UNITED STATES DEPARTMENT OF AGRICULTURE
PUBLICATIONS ABSTRACTED

Technical Bulletin—	Page
631. The Storage of Sweet Cherries as Influenced by Carbon Dioxide and Volatile Fungicides, F. Gerhardt and A. L. Ryall.....	41
633. Principles of Gully Erosion in the Piedmont of South Carolina, H. A. Ireland, C. F. S. Sharpe, and D. H. Eargle	339
634. Food of Game Ducks in the United States and Canada, A. C. Martin and F. M. Uhler.....	538
637. Subsoil Moisture Under Semiarid Conditions, J. S. Cole and O. R. Mathews.....	478
638. Temperature and Other Factors Affecting the Germination of Fescue Seed, V. Kearns and E. H. Toole.....	360
640. Growth of Lemon Fruits in Relation to Moisture Content of the Soil, J. R. Furr and C. A. Taylor.....	652
643. Food Habits of North American Diving Ducks, C. Cottam.....	538
644. The Chemical Determination of Soundness in Corn, L. Zeleny and D. A. Coleman.....	8
645. Manufacturing and Serviceability Tests on Sheetings Made From Two Selected Mill Types of Cotton, R. E. Rogers, M. B. Hays, and J. T. Wigington.....	602
651. Forest Fire Insurance in the Northeastern States, H. B. Shepard.....	444
652. Flow of Water in Irrigation and Similar Canals, F. C. Scobey.....	580
653. A Revision of the Mites of the Subfamily Tarsoneminae of North America, the West Indies, and the Hawaiian Islands, H. E. Ewing.....	82
659. The Sand Wireworm and Its Control in the South Carolina Coastal Plain, J. N. Tenhet and E. W. Howe.....	80
663. Effect of Cleaning Seed Cotton on Lint Quality and Ginning Efficiency, F. L. Gerdes, A. J. Johnson, and C. A. Bennett.....	288
667. Wintering Steers on Different Planes of Nutrition from Weaning to 2½ Years of Age, W. H. Black, J. R. Quesenberry, and A. L. Baker.....	258
668. Bruising, Freezing, and Chemical Injury of Potatoes in Transit, R. C. Wright.....	207
669. Fertilizer Placement for Potatoes, G. A. Cumings and G. V. C. Houghland.....	507
670. Relation of Temperature and Moisture Content to Longevity of Chewings Fescue Seed, V. Kearns and E. H. Toole.....	366
671. Composition and Properties of Goat's Milk as Compared With Cow's Milk, J. A. Gamble, N. R. Ellis, and A. K. Besley.....	564
672. Vapor-Heat Treatment for the Control of Narcissus Bulb Pests in the Pacific Northwest, R. Latta.....	674
673. The Distribution of Insects, Spiders, and Mites in the Air, P. A. Glick.....	673
674. Breaking Strength, Elongation, and Folding Endurance of Films of Starches and Gelatin Used in Textile Sizing, M. S. Furry.....	460
675. Sewage Irrigation as Practiced in the Western States, W. A. Hutchins.....	426
676. Shrinkage and Cooking Time of Rib Roasts of Beef of Different Grades as Influenced by Style of Cutting and Method of Roasting, L. M. Alexander and N. G. Clark.....	447

Technical Bulletin—Continued.

Page

677. Experiments in Breeding Holstein-Friesian Cattle for Milk- and Butterfat-Producing Ability, and an Analysis of the Foundation Cows and of the First Outbred Generation, M. H. Fohrman and R. R. Graves..... 771
678. A Chemical Study of Some Soils Derived from Limestone, L. T. Alexander, II G. Byers, and G. Edgington..... 760
679. Studies on the Development of the Pigeon Capillariid, *Capillaria columbae*, E. E. Wehr..... 848

Farmers' Bulletin—

1812. Native and Adapted Grasses for Conservation of Soil and Moisture in the Great Plains and Western States, M. M. Hoover..... 202
1814. Terrace Outlets and Farm Drainageways, C. L. Hamilton..... 851
1817. Growing Wheat in the Eastern United States, S. C. Salmon and J. W. Taylor..... 644
1818. Mechanical Milk Cooling on Farms, J. R. McCalmont..... 119
1819. Infectious Anemia (Swamp Fever), W. S. Gochenour, C. D. Stein, and O. L. Osteen..... 111
1820. Silo Types and Construction, J. R. McCalmont..... 853
1821. Containers for Fruits and Vegetables, L. C. Carey..... 513
1822. Seed Corn, M. T. Jenkins..... 506

Statistical Bulletin—

64. Statistics of Forest Products in the Rocky Mountain States, R. V. Reynolds and A. H. Pierson..... 46
65. Forest Products Statistics of the Pacific Coast States, compiled by R. V. Reynolds and A. H. Pierson..... 47
66. Stumpage and Log Prices for the Calendar Year 1937, compiled by H. B. Steer..... 47

Circular—

491. Grass Culture and Range Improvement in the Central and Southern Great Plains, D. A. Savage..... 202
506. Control of the Corn Earworm on Fordhook Lima Beans in Eastern Virginia, L. W. Brannon..... 248
507. Diets of Families of Employed Wage Earners and Clerical Workers in Cities, H. K. Stiebeling and E. F. Phipard..... 142
509. Mushroom Casing Soil in Relation to Yield, E. B. Lambert and H. Humfeld..... 514
510. Air-Blast Gin Performance and Maintenance, A. J. Johnson and T. L. Bagette..... 119
511. Control of Black Rot of Pineapples in Transit, C. O. Bratley and A. S. Mason..... 62
512. Longevity of Onion Seed in Relation to Storage Conditions, J. H. Beattie and V. R. Boswell..... 212
513. Curly-Top-Resistant Sugar-Beet Varieties in 1938, F. V. Owen, F. A. Abegg, A. M. Murphy, B. Tolman, C. Price, F. G. Larmer, and E. Carsner..... 58
514. Differential Staining of Sections of Unpreserved Bovine Udder Tissue Affected With Mastitis, W. T. Miller and H. W. Johnson..... 282
515. Handling and Shipping Strawberries Without Refrigeration, D. F. Fisher and J. M. Lutz..... 216
516. Control of Cyclamen and Broad Mites on Gerbera, F. F. Smith..... 401
517. The Northstar Strawberry, G. M. Darrow..... 44

Circular—Continued.

Page

518. Breeding Areas and Economic Distribution of the Beet Leaf-hopper in New Mexico, Southern Colorado, and Western Texas, V. E. Romney.....	246
519. The Tobacco Industry in Puerto Rico, C. E. Gage.....	293
520. Wildlife of the Atlantic Coast Salt Marshes, W. L. McAtee.....	391
521. Studies of Gaps in Sugarcane Rows and Their Effect Upon Yield Under Louisiana Conditions, G. Arceneaux and I. E. Stokes....	508
522. A Soft Cheese of the Bel Paese Type, R. R. Farrar.....	415
524. Determination of Slaughter-Steer Grades From Weights and Measurements, B. Knapp, Jr.....	557
525. Artificial Insemination of Chickens and Turkeys, W. H. Burrows and J. P. Quinn.....	773
528. New Chrysanthemums, F. L. Mulford.....	519

Leaflet—

170. Date Growing in the United States, R. W. Nixon and D. C. Moore..	44
171. The Timothy Crop, M. W. Evans.....	208
172. Why Fruit Trees Fail to Bear, H. P. Gould.....	44
173. The Bud-Graft Method of Propagating Vinifera Grape Varieties on Rootstocks, E. Snyder and F. N. Harmon.....	44
174. Bean Bacterial Wilt, F. Hedges.....	229
175. Eradication of the Cultivated Black Currant in White Pine Regions, J. F. Martin.....	233
177. The Pasteurization of Milk, C. J. Babcock.....	102
178. Dwarf Fruits, H. P. Gould.....	44
179. The Native Papaw, H. P. Gould.....	44
180. How to Keep and Increase Black Grama on Southwestern Ranges, R. S. Campbell and E. C. Crafts.....	39
181. Drying Seed Cotton, F. L. Gerdes, W. J. Martin, and C. A. Bennett..	583
182. Housefly Control, F. C. Bishopp.....	683
183. Cankerworms, T. H. Jones.....	680
184. The Elm Leaf Beetle, C. W. Collins.....	821

Miscellaneous Publication—

269. A Graphic Summary of Farm Animals and Animal Products, O. E. Baker.....	296
318. 4-H Club Insect Manual, M. P. Jones.....	300
319. Plans of Farm Buildings for Western States.....	119
322. Housing Requirements of Farm Families in the United States, M. Wilson.....	318
323. The Farm-Housing Survey.....	318
326. Forest Resources of Southeastern Texas, J. W. Cruikshank and I. F. Eldredge.....	46
334. Land Facts on the Southern Plains, G. K. Rule.....	171
335. Workers in Subjects Pertaining to Agriculture in Land-Grant Colleges and Experiment Stations, 1938-39, M. A. Agnew.....	300
336. The Mosquitoes of the Southeastern States, W. V. King, G. H. Bradley, and T. E. McNeel.....	819
337. Abbreviations Used in the Department of Agriculture for Titles of Publications, C. Whitlock.....	750
339. Family Income and Expenditures: Pacific Region.—I, Family Income, D. Monroe, M. S. Weber, and H. Hollingsworth.....	603
341. The Species of <i>Pantomorus</i> of America North of Mexico, L. L. Buchanan.....	822

Miscellaneous Publication—Continued.

Page

342. Hosiery for Women, A Buying Guide, M. Smith.....	461
343. Directory of Field Activities of the Bureau of Biological Survey, 1939	803
346. Short-Time Camps: A Manual for 4-H Leaders, E. Gardner.....	733
347. Lumber Requirements for Nonfarm Residential Construction, F. J. Hallauer.....	427
348. Federal Legislation, Rulings, and Regulations Affecting the State Agricultural Experiment Stations.....	603
349. Use of the Rapid Whole-Blood Test for Pullorum Disease, H. Bunyea	847
350. The Wildlife Restoration Program Under the Pittman-Roberston Act of 1937, A. M. Day.....	390

EXPERIMENT STATION RECORD

VOL. 81

JULY 1939

No. 1

JACOB GOODALE LIPMAN, 1874-1939

The sudden death on April 19, 1939, of Dean and Director Jacob Goodale Lipman of New Jersey removed from the land-grant institutions a leader of unique personality and comprehensive interests. Overcoming many handicaps, his career had been one of consistent advancement and increasing influence. There have been few men in comparable positions who have become more widely known or whose assistance in the development of agricultural science has been sought and rendered more freely.

Dr. Lipman's success has been a logical result of his keen mentality, his genius for organization, and his unsparing industry. To an unusual degree he rose by his own efforts. Born in Friedrichstadt, Russia, on November 18, 1874, he came to the United States when a boy of 14, and for a time was employed in a law office in New York City. In 1891 his family settled in the Baron de Hirsch Colony at Woodbine, N. J., where he made his first contacts with practical farming in the reclamation and development of the scrub oak land of the region and studied agriculture in the farm school. Three years later he won a State scholarship in Rutgers University, meeting his college expenses largely by farm work and the testing of cattle for advanced registry, then in its early stages. He received the B. S. degree in 1898 and was appointed assistant chemist in the fertilizer inspection laboratory of the station. The next year he took up graduate work in soil chemistry and bacteriology at Cornell University, earning the M. A. degree in 1900 and the Ph. D. degree in 1903.

Even before the completion of his studies, Dr. Lipman was invited to return to New Jersey to organize what was probably the first station department of soil chemistry and bacteriology. He entered upon this pioneer field in 1901, and in the succeeding decade built up a considerable staff, equipment, and program.

Much of his work was carried on in close association with Director E. B. Voorhees, and upon the death of the latter in 1911 the selection of Dr. Lipman as his successor was in keeping with the tradition of the institution. He soon announced a policy of enlarged service based

upon a wider publicity for the work, a more effective dissemination of the station results, and an increased specialization. Within 3 years five new departments had been established—poultry husbandry, seed analysis, plant pathology, agronomy, and farm management and extension—and the work in animal and dairy husbandry had been divided. The inspection service was made more effective. Cranberry and blueberry investigations were begun in 1916, and egg-laying and breeding contests in 1917.

These somewhat radical beginnings in a relatively conservative environment were continued in later years. The physical plant was greatly enlarged, with practically a complete set of new and substantial buildings and much additional land and equipment. Substantially increased income was obtained. For the fiscal year 1912 the State appropriated \$89,048 for the work of the State station; in 1938 the comparable State funds available were \$512,090. While numerous factors entered into this expansion, by no means the least were the unusual foresight and shrewd business management of Dr. Lipman and the support and confidence which he had inspired among the people of a State not primarily agricultural in its economic and social outlook.

Arduous and punctiliously performed as were the duties of the station directorship, they absorbed only a fraction of Dr. Lipman's energies. In 1902 he had been made instructor in agricultural chemistry, in 1906 assistant and associate professor, and in 1910 he became professor of soil fertility and bacteriology. Since 1913 he had been professor of agriculture, and since 1915 dean of the College of Agriculture. He had also continued as chief of the station division of soils and crops. In all these he rendered effective service. As his biographer in the station history pointed out in 1930, "Dr. Lipman has made soil science a live and glowing subject for scores of students—graduate and undergraduate. His researches and writings have been fundamental and brilliant. But together with scientific research he has been able to combine the very difficult, often exacting, task of administration."

Added to his services for Rutgers and the New Jersey Stations, formally recognized in 1923 by the conferring upon him by the university the honorary degree of doctor of science, was a sustained participation in a remarkable range of interests of national and international scope. Prominent among these inevitably was the Association of Land-Grant Colleges and Universities. He was very active in this organization, holding many offices and performing much useful committee service. He was elected vice president for 1928 and president for 1936, delivering in the latter year an address entitled *The Land-Grant and Our Land*, in which he visualized some of the

accomplishments of the land-grant institutions and Federal Department of Agriculture and pointed out numerous problems awaiting solution.

Dr. Lipman was a charter member of the American Society of Agronomy in 1907 and the founder of *Soil Science* in 1916. He served as editor-in-chief of this journal throughout the succeeding years, as well as associate editor of a number of other scientific journals. His own publications were also voluminous, including a long list of technical papers on soils, soil bacteriology, agronomy, and many other phases of agriculture and country life.

In the field of international relations it seems probable that no representative of American agricultural science has had more extended and intimate contacts. He was a member of several European academies of agriculture, many foreign societies, commissions, and other groups, and the recipient in 1930 of the degree of honorary doctor from the Catholic University of Santiago, Chile, and an honorary membership in the faculty of the University of Santiago. His most conspicuous service in this connection was with international soil science meetings. He was active in the 1922 conference in Praha and the Roma conference in 1924, served as president of the First International Congress of Soil Science held in Washington, D. C., in 1927, and was chairman of the American delegation to the 1935 meeting in Oxford. Of these the Washington congress imposed exceptionally heavy responsibilities, including the burden of financing as well as the planning and execution of the program. Its success was due in no small degree to his personal efforts and influence.

Needless to say, Dr. Lipman led a very busy life and one which was highly productive. Not only Rutgers and New Jersey but the land-grant institutions as a national group may well take pride in his achievements, for he was a conspicuous representative of a class of youth with limited means and outlook which they were established to reach and serve. To Rutgers and Cornell he owed his sound technical training, the inspiration of such pioneers as Voorhees, Caldwell, and V. A. Moore, and the opening of the door of research opportunity. These debts he speedily repaid by his exceptional public service. So long as the land-grant institutions can develop and put to work investigators, educators, and administrators such as he, their usefulness in a democracy can be readily justified.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations by the Iowa Station] (*Iowa Sta. Rpt. 1938, pts. 1, pp. 102, 123; 2, pp. 61-69, fig. 1*).—Research work on nitrogen and accessory growth factor requirements of bacteria, especially the lactic and propionic acid forms, by C. H. Werkman; and on development of the use of clay, particularly Iowa clay, for the clarification of sorghum sirup, by W. G. Gaessler and J. T. Lonsdale, is reported in part 1. In part 2, dealing with the Iowa Corn Research Institute, certain chemical and physical characteristics of corn as related to industrial utilization, oxidation of cornstarch, and identification of the compounds responsible for the odor of yellow corn are reported upon by R. M. Hixon; a characterization of the products of starch degradation by enzyme, by N. Naylor; physical properties of dextrose, by J. H. Buchanan; and utilization of agricultural products in the fermentative production of lactic acid, by Werkman.

[Bacteriological chemistry investigations by the Wisconsin Station] (*Wisconsin Sta. Bul. 442 (1938), pp. 62-64, 65-67*).—Lactic acid bacteria have been studied by E. E. Snell and F. M. Strong, butyric acid anaerobes by L. E. McDaniel and D. W. Woolley, fermentation of wood sugar liquor, by N. O. Sjolander, products of propionic acid bacteria by A. S. Phelps and M. J. Johnson, industrial production of lactic acid by S. C. Pan, enzymes of micro-organisms by J. Berger and Johnson, and physiology of anaerobic bacteria by E. McCoy, C. Lankford, Sjolander, and N. Rodgers; and yields of yeast, role of phosphorus, spoilage of bakers' yeast, and oxidation-reduction relationships, by D. Collingsworth, W. L. Owen, and I. L. Baldwin.

Some notes on the stability of dithizone solutions, P. A. CLIFFORD. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem., 21 (1938), No. 4, pp. 695-703, figs. 3*).—The instability of dithizone solutions in chloroform was found to be due to the decomposition of the solvent rather than to instability of the reagent itself. Solutions in purified chloroform stabilized by the addition of 1 percent of its volume of pure absolute alcohol. Chloroform solutions of the reagent kept well enough when stored in darkness and at a temperature of 40° F. to permit standard solutions to be prepared in considerable quantities and held for some time. Carbon tetrachloride, as well as chloroform, was improved by purification but added alcohol was not needed. Storage of carbon tetrachloride solutions of dithizone in the cold and dark under a layer of sulfur dioxide water of about 0.1 M strength will preserve them almost indefinitely.

A chemical examination of the lignin-like substance from the sporophores of *Fomes pini* (Thore) Lloyd (*Trametes pini* (Thore) Fr.), M. PHILLIPS. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem., 21 (1938), No. 4, pp. 678-684*).—The author isolated from the sporophores of *F. pini*, by extraction either with fuming hydrochloric acid or with diluted hydrochloric acid and ethylene glycol monomethyl ether and subsequent precipitation, a substance resembling lignin in some chemical reactions but differing from lignin of seed plants in being essen-

tially free from methoxyl groups. Results of chlorination, bromination, nitration, acetylation, methylation with diazomethane and with dimethyl sulfate, and alkali fusion are given.

The dehydrogenation of alkali lignin from corn cobs with selenium, M. PHILLIPS and M. J. Goss. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 21 (1938), No. 4, pp. 632-635).—Alkali lignin from corncobs was distilled with selenium in an atmosphere of nitrogen. From the oil obtained guaiacol and 1-*n*-propyl-3-methoxy-4-hydroxybenzene were isolated and identified as their 3,5-dinitrobenzoyl esters. The neutral fraction of the oil consisted of a mixture of selenium-containing organic substances, which appeared to be mixtures of organic selenides. The fraction boiling between 155° and 160° C. was found to contain 80.71 percent (average) of selenium. There was also isolated a crystalline substance melting at 122° (corrected), which appeared to be identical with the one previously isolated from the oil obtained in the dry distillation of lignin from corncobs. No hydrocarbon that would throw light on the structure of lignin was isolated.

Seasonal variation in tannin content of *Lespedeza sericea*, I. D. CLARKE, R. W. FREY, and H. L. HYLAND. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 2, pp. 131-139, fig. 1).—Because of its possible influence upon palatability to cattle and upon digestibility, the tannin content of the leaves of this forage plant was determined in cuttings taken each week from the end of May to the end of July.

Total tannin in the leaves increased from 7.5 to 18 percent, and fixable tannin increased from 3.8 to 11.6 percent. The last cutting (a decrease of the percentage of leaves from 61.6 to 42.8 being taken into consideration) contained about 2½ times as much total tannin and 3 times as much fixable tannin as the first cutting. Not only the quantity of tannin in the leaves but also the astringency of the tannin increased during spring and summer. The quantity of total tannin in the stems was relatively insignificant, ranging only from 1 to 1.6 percent. In the whole plant the percentages of total and fixable tannin were essentially constant except for the three earliest cuttings.

The formaldehyde precipitation method gave results differing by a constant factor from those obtained in total tannin determinations. It is therefore considered that under some conditions the formaldehyde method might be a convenient procedure for approximate estimations.

Further studies on the nature of *Ricinus* lipase and its action, H. E. LONGENECKER and D. E. HALEY. (Pa. Expt. Sta.). (*Jour. Amer. Chem. Soc.*, 59 (1937), No. 11, pp. 2156-2159, figs. 2).—An arbitrary expression for comparing the lipolytic activity of preparations from the seeds of the castor-bean plant is based on the time required for 40 percent hydrolysis of an oil. Variation of the substrate concentration and the amount of water in the digestive mixture have shown the optimum conditions for *Ricinus* lipase action and the variance permissible for considerable action. Lipolytic action in the presence of a trace of water was observed and is considered to suggest the utility of the enzyme to the germinating seed. Inactivation of this enzyme by water was found to take place in the presence or absence of oil.

The effect of certain salts and cholesterol on the activity of *Ricinus* lipase, H. E. LONGENECKER and D. E. HALEY. (Pa. Expt. Sta.). (*Jour. Amer. Chem. Soc.*, 59 (1937), No. 11, pp. 2160, 2161, fig. 1).—The effect of certain salts, chiefly chlorides and acetates, on the activity of *Ricinus* lipase was studied. All of these were found to retard or inhibit the normal action of the enzyme. Salts of copper, cobalt, and mercury showed the greatest inhibitory action. The least inhibitory effects were those of iron, lead, nickel, and zinc salts. Cholesterol

accelerated the action of the enzyme, indicating that a water-in-oil emulsion is desirable for its optimum activity.

[A. O. A. C. reports presented at the 1937 meeting] (*Jour. Assoc. Off. Agr. Chem.*, 21 (1938), No. 4, pp. 531-533, 552-554, 594, 595, 596, 596-600, 614-618, 622-625).—Reports on analytical methods and on collaborative studies of such methods have been reported from land-grant institutions as follows: Santonin, phenolphthalein, and calomel in tablets, and pyridium, both by H. J. Fisher (Conn. [New Haven]); feeding stuffs, by L. S. Walker (Vt.); stock feed adulteration, by P. B. Curtis (Ind.); mineral mixed feeds, by A. T. Perkins and J. F. Merrill (Kans.); hydrocyanic acid in glucoside-bearing materials, by R. A. Greene (Ariz.); and biological methods for vitamin B complexes, by C. A. Elvehjem (Wis.).

[Studies of chemical methods by the Cornell Station], B. L. HERRINGTON, P. F. SHARP, V. N. KRUKOVSKY, D. B. HAND, L. C. NOERIS, and A. Z. HODSON ([*New York*] *Cornell Sta. Rpt.* 1938, pp. 106, 107, 147, 148).—Procedures for determining the total-solids content of milk from the fat and specific gravity, factors involved in the determination of moisture in milk products, a seeding test for the detection of crystalline β -lactose, a quantitative method for determining the relative amounts of α - and β -lactose in dried milk and whey, a method for more satisfactory analysis of composite samples by the Babcock test, and methods for determining the riboflavin content of feedstuffs are briefly noted.

Influence of arsenical treatments upon rapid tests for soil phosphorus, M. S. ANDERSON and J. W. BENGTSON. (U. S. D. A. et al.). (*Jour. Amer. Soc. Agron.*, 30 (1938), No. 10, pp. 844-846).—The authors show that where lead arsenate has been applied in large quantities or repeatedly, as in Japanese beetle control, rapid test methods for determining soil phosphate requirement will give high results for phosphate content. From the data presented "it is evident . . . that the relative quantities of phosphorus or arsenic, or both, dissolved by the different extracting solutions vary somewhat but show the same general trends. It is clear, also, that rapid tests for phosphorus, as ordinarily conducted, are meaningless when soils have received any kind of arsenical treatments."

Determination of chlorate in soil extracts, culture solutions, and plant sap, R. S. ROSENFELS. (Calif. Expt. Sta. and U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 21 (1938), No. 4, pp. 665-674).—The first of the two methods reported upon is based upon the reduction of chlorate to chloride by sulfurous acid. The chloride is determined before and after reduction by titration with silver nitrate, the difference being a measure of the amount of chlorate. Recovery tests on known amounts of chlorate show that the method gives reliable results on soil extracts. A shorter procedure is based upon the reduction of chlorate by hydriodic acid followed by titration of the resulting iodine with thiosulfate. Recovery tests showed that this method is not suited to the analysis of soil extracts but gives reliable results on culture solution. It was also satisfactory for the analysis of xylem sap of squash.

Determination and occurrence of boron in natural phosphates, superphosphates, and defluorinated phosphate rocks, L. F. RADER, JR., and W. L. HILL. (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 57 (1938), No. 12, pp. 901-916, figs. 2).—The authors have so far modified the methyl ester distillation method as to permit titration with a single indicator (phenolphthalein) instead of two indicators. The boron contents (acid-soluble boron (B_2O_3)) as thus determined are given for 54 samples of natural phosphates from various deposits of the world as ranging from <10 to 144 p. p. m., in 9 samples of superphosphates from <10 to 158 p. p. m., and in 3 samples of defluorinated phosphate rock from 20 to 30 p. p. m.

Concerning the Dyer method for the identification and determination of volatile fatty acids, E. P. CLARK and F. HILLIG. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 21 (1938), No. 4, pp. 684-688, figs. 3).—A critical study of the method has revealed that the distillation constants of the various acids depend largely upon the size and design of the apparatus, as well as upon the rate of distillation. "The values recorded by Dyer [*E. S. R.*, 37, p. 13] are obtained, therefore, only under the exact conditions used by him, and since the instructions given in his paper are inadequate, his results are not reproducible."

The authors present a fully dimensioned diagram of a distillation apparatus giving reproducible results, specifying not only dimensions of all parts affecting the distillation rates but also the angles of bends in the connecting tubing. Steam is obtained from a 3-l. Erlenmeyer flask provided with an immersed 25-ohm coil of No. 30 Chromel wire connected in series with a 22-ohm variable resistance for accurate control of the rate of steam elevation. These heating unit and resistance specifications are for 110 v.

Application of the Scales method to determination of sugar in plant juices and tissues, W. R. ROY and A. E. HUGHES. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 21 (1938), No. 4, pp. 636-645, figs. 2).—The Benedict alkaline copper solution is used, the cuprous oxide being oxidized by a known excess quantity of standard iodine solution in the presence of hydrochloric acid in the original reaction mixture, in which also the back titration of the excess iodine with standard thiosulfate solution is carried out.

The sodium thiosulfate-sugar equivalent was determined by means of regression lines of volume of sodium thiosulfate on milligrams of dextrose and sucrose, covering the range considered. A statistical study of these ratios showed them to be linear. A method for the determination of the blank, based on the fact that linear regression lines were obtained, was developed. The effect of period of boiling on the amount of sugar recovered was studied, the optimum time of actual boiling having been found to be 3 min. Back oxidation was controlled during cooling by minimum agitation of the flask in which the determination was being made. A statistical study of the error in the amount of sugar, estimated at various concentrations and covering the entire range of the method, showed that the method is reliable between the limits 4-18 mg. of sugar. A statistical comparison of the Scales method as modified and the standard method of Munson and Walker, as applied both to pure sugar solutions and to fruit juices, showed equal accuracy.

An improved technic in the toluene distillation method for the determination of moisture in foodstuffs, J. A. DE LOUREIRO (*Jour. Assoc. Off. Agr. Chem.*, 21 (1938), No. 4, pp. 645-648, fig. 1).—Satisfactory results are obtained with the Bidwell and Sterling direct method for water estimation (*E. S. R.*, 53, p. 805) under the following conditions: (1) An apparatus allowing a flow of liquid in the same direction as the flow of vapors must be used. (2) The collecting tube must be rinsed with a strongly alkaline solution before the estimation is begun. (3) Liberation of volatile fatty acids must be prevented by the addition of a small quantity of anhydrous disodium phosphate. A dimensioned diagram shows the construction of the apparatus necessary for this modification of the method.

A note on the bioassay technique for determining available iron in foods, P. L. HARRIS and G. L. POLAND (*Food Res.*, 3 (1938), No. 4, pp. 383-388, fig. 1).—Data are presented confirming the recommendations of Smith and Otis (*E. S. R.*, 78, p. 888) for the modification of the Elvehjem and Kemmerer bio-assay procedure (*E. S. R.*, 67, p. 90) for determining available iron in foods of low iron content.

The chemical determination of soundness in corn, L. ZELENY and D. A. COLEMAN (*U. S. Dept. Agr., Tech. Bul. 644* (1939), pp. 24, figs. 3).—It has been shown that the quantity of free fatty acids, amino acids, and acid phosphates in the kernel tend to increase as deterioration progresses. Only the fat acidity, however, increases significantly with incipient deterioration and is therefore the only type of acidity which appears to be useful in differentiating degrees of soundness in corn. For the samples included in this study the average increase in fat acidity between grades No. 1 and No. 2 is 20 times as great as the average increase in phosphate acidity and 59 times as great as the increase in aminic acidity. Fat acidity based on the sample as a whole appears to be a more reliable index of soundness than fat acidity based on the extracted fat.

A soundness score has been devised as a mathematical expression based on percentage of damaged kernels, germinability, fat acidity, amino acid acidity, and phosphate acidity as criteria of soundness. In a series of 244 samples of corn, fat acidity values correlated more closely with the soundness score than did the percentages of damaged kernels.

A rapid method of determining fat acidity has been devised by which 75 to 100 determinations may be made in a 7-hr. day by an analyst with the aid of one nontechnical assistant, the method thus being usually more rapid than the damaged-kernel method.

A chemical procedure for evaluating spoilage in canned fish, especially salmon and tuna fish, F. HILLIG and E. P. CLARK. (*U. S. D. A.*). (*Jour. Assoc. Off. Agr. Chem.*, 21 (1938), No. 4, pp. 688-695, fig. 1).—The authors found the production of volatile acids to be characteristic of the spoilage in question and adapted the Dyer method (*E. S. R.*, 37, p. 13) to the purpose of obtaining an index of the degree of spoilage.

"A critical examination of the extensive data accumulated shows that for practical diagnostic purposes it is not necessary to determine the entire quantity of acid in a sample, nor is it necessary to identify all the components of the mixture. What is essential is to determine accurately a definite proportion of the total acids which has been called the volatile acid number, and the quantity of formic acid in this fraction, designated as the 'formic acid number.'"

The preparation of samples of canned dog food for chemical analysis, C. J. KOEHN (*Alabama Sta. Rpt. 1937*, p. 24).—A method devised by the station is described.

Observations on the determination of ash in feeding stuffs, J. W. CLULOW (*Jour. Assoc. Off. Agr. Chem.*, 21 (1938), No. 4, pp. 674-678).—The author notes that although the proportion of calcium carbonate used in a mixed feed is usually small, it may amount to from 15 to 30 percent of the ash, making uniformity in the decomposition of the carbonate essential to uniformity of ash determination results. He found that oven control is erratic at 550° C., the decomposition of the calcium carbonate ranging from 17 to 100 percent. A temperature of 650° maintained for from 15 to 18 hr. or a temperature of 700° maintained for 2 hr. gave more uniform results, "but there is still considerable room for improvement."

The colorimetric determination of pH in milk and whey by means of the "Wulff" pH tester, R. ASCHAFFENBURG (*Jour. Dairy Res. [London]*, 9 (1938), No. 3, pp. 336-338).—A comparison of pH values for milk and whey obtained by the Wulff colorimetric and potentiometric methods is reported. Good agreements of values were obtained for the whey, while somewhat wide variations occurred with milk. The value of the colorimetric method for following pH changes in whey during cheese manufacturing is suggested.

The estimation of sulfanilamide in milk, H. BAUER and M. F. GUNDERSON. (Univ. Nebr.). (*Cornell Vet.*, 28 (1938), No. 4, pp. 299-304, fig. 1).—It was found that sulfanilamide in the milk of goats or cows can be estimated by the method described by Fuller in 1937 (*E. S. R.*, 77, p. 849). The errors encountered by this method ranged from 0.4 to 4 percent, but the results with human milk were disappointing. "Duplicate milk samples containing known amounts of sulfanilamide and the requisite amount of trichloroacetic acid when held at refrigerator temperature for a period of 24 hr checked within 0.4 to 4 percent. Likewise duplicate samples which did not contain trichloroacetic acid but were held in the refrigerator for 24 hr. checked within 0.6 to 4 percent. Determinations made immediately on duplicate milk samples containing known amounts of sulfanilamide checked within 1 to 4 percent. The results obtained would seem to indicate that neither the addition of trichloroacetic acid nor the holding of the milk samples at refrigerator temperature for 24 hr. markedly interferes with the accuracy of the test. Of the 23,349 mg of sulfanilamide fed to the goat, only 79.054 mg. were recovered at the end of 60 hr. . . . Of the several hundred sulfanilamide determinations made on herbivore milk samples, no technical difficulties were encountered using Fuller's modified method."

Use of phenol in application of Prebluda-McCollum reagent for determining vitamin B₁, D. MELNICK and H. FIELD, JR. (*Soc. Eapt. Biol. and Med. Proc.*, 38 (1938), No. 5, pp. 723-725, fig. 1).—The authors have found that xylene quantitatively extracts the pigment formed in the color test for vitamin B₁ described by Prebluda and McCollum (*E. S. R.*, 77, p. 151), and that in the presence of phenol there is a marked increase in the sensitivity of the reaction, the xylene later becoming intensely pigmented. The quantities of the various reagents used in the test were 100γ of thiamine chloride in 10-cc. solution at pH 7, 20 cc. of the Prebluda-McCollum reagent, and 50 mg. of phenol. After 24 hours' standing at room temperature, 2 cc. of the xylene is added, the mixture is shaken vigorously for 1½ min., centrifuged, and the color of the xylene layer then compared in a microcolorimeter with a standard similarly treated. The intensity of color in the presence of phenol has made possible a micromethod, using 3/10 quantities of the vitamin solution, phenol, and color reagent, but the original quantity of xylene. By this procedure it is said to be possible to determine accurately the vitamin B₁ concentration in solutions containing as little as 10γ total of thiamine chloride. The reaction in its present form cannot be applied as yet to biological materials unless quantitative procedures for the preparation of suitable concentrates are first devised.

Use of cyanide in the determination of ascorbic acid, M. CUSHMAN and A. M. BUTLER (*Soc. Eapt. Biol. and Med. Proc.*, 39 (1938), No. 3, pp. 534-539).—Conflicting views as to the advisability of adding KCN to blood samples to be used in the determination of ascorbic acid have led to a reinvestigation of the effect of KCN on 2,6-dichlorophenolindophenol and the stability of reduced ascorbic acid in whole blood, plasma, and plasma filtrate, with the finding that KCN may or may not invalidate the results, depending upon the concentration of the salt and the pH of the dye-salt solution. It was also demonstrated that reduced ascorbic acid is stable in whole blood or metaphosphoric acid plasma filtrates for as long as 24 hr., but that there is a significant loss when plasma stands at room temperature for more than 4 hr. and that this loss is not prevented by the presence of KCN in the concentrations recommended. The authors conclude that there is no reason for the addition of potassium cyanide in the determination of plasma ascorbic acid by the methods tested.

Direct reading catalase test tubes, E. R. CARLSON. (*Wis. Expt. Sta.*). (*Cornell Vet.*, 28 (1938), No. 4, pp. 331-339, figs. 4).—Two forms of a direct read-

ing catalase test tube are described and illustrated. The capillary type is designed for field use, while the other is especially suited for the laboratory. Both types have the innovation of a scale for direct reading of the percentage of oxygen gas without resorting to computation. The laboratory type in addition makes use of a pigmented agar indicator to facilitate reading. Methods of determining percentages higher than 200 percent with the use of the laboratory type test are described. Both types are designed to facilitate self-measurement of fluids used in the catalase test.

Photo-colorimetric method for the determination of androsterones in urine. R. NEUSTADT (*Endocrinology*, 23 (1938), No. 6, pp. 711-717, figs. 2).—A photo-colorimetric method is described for the determination of androsterones in urine.

Keeping quality of crackers improved by antioxygen. H. O. TRIEBOLD. (Pa. Expt. Sta.). (*Food Indus.*, 10 (1938), No. 2, pp. 71, 111, 112).—Oat flour and its extracts were found to have some antioxidant properties, inhibiting for a time the oxidative deterioration of crackers stored at elevated temperatures. It was found that the best way to add the antioxidant is to spray the crackers with the extract immediately upon their removal from the oven. Dusting the crackers with oat flour just previous to baking also aided in retarding rancidity development.

Potato by-products studies. C. A. BRAUTLECHT (*Maine Sta. Bul.* 391 (1938), pp. 305, 306).—Studies, principally concerned with starch production problems and including analyses, are reported.

[Better prune products] (*Oregon Sta. Circ.* 130 (1938), pp. 44, 45, figs. 3).—This is a brief general article containing notes on five new prune products. These are canned dried prunes, prune juices, prune pulp, dried prune halves, and dried prunes in small packages. The desirability of a quality standard to replace the present size standard is also pointed out.

List of publications on pulp and paper. (Coop. Univ. Wis.). (*U. S. Dept. Agr., Forest Serv., Forest Prod. Lab.*, 1938, pp. [2]+19).—Technical notes, reprints, mimeographed reports, etc., obtainable upon request from the Forest Products Laboratory at Madison, Wis., as long as available, are listed.

List of references to the literature on tall oil (tallol, liquid rosin, pine oil, or black liquor soap), M. W. BRAY, J. S. MARTIN, and L. H. SMITH. (Coop. Univ. Wis.). (*U. S. Dept. Agr., Forest Serv., Forest Prod. Lab.*, 1938, rev., pp. [1]+9).—This list contains 98 references, mostly to foreign publications, of which a considerable number report Swedish work on this material. A brief account is appended of the manufacture, constituents, purification, and uses of liquid rosin or tall oil (Swedish "tall" equals pine).

AGRICULTURAL METEOROLOGY

Weather. G. PICKWELL (*Los Angeles: Hugh F. Newman & Co.*, 1937, pp. x+170, [figs.] 59).—This popular treatise discusses the subject under the headings: Why study weather, what makes the weather (sun, air, water, cyclones and anticyclones, and cyclones and seasons), signs of the weather (clouds, winds, and lightning), the work of the weather (by winds, water, and sun), what man does about the weather (recording and predicting the weather, and control of wind, floods, erosion, and frost), and learning the weather (by younger and older students).

The daily exploration of the atmosphere by radiosond [trans. title], R. BOURGEOIS (*Compt. Rend. Acad. Sci. [Paris]*, 207 (1938), No. 15, pp. 611-613).—The author describes and discusses the meteorological application of the radiosond

balloon to the instantaneous recording of temperature, pressure, and humidity data from high atmospheric altitudes.

Structure of the lower stratosphere [trans. title], V. MIRONOVITCH and A. VIAUT (*Compt. Rend. Acad. Sci. [Paris]*, 207 (1938), No. 19, pp. 866-869, figs. 2).—The authors examine certain theories of the structure of the tropopause on the basis of information from daily temperature soundings. The effect of invasion by polar air originating in latitude 50° and reaching latitude 35° is examined, curves from actual soundings being compared with theoretical data, and a similar study is made of invasion by tropical air, with corresponding curves. The effects of such invasions are discussed, with particular reference to what the authors call the division ("dédoublément") of the tropopause. This effect is said to be very often a sign that a change in type of weather is in progress.

Atmospheric ozone as a constituent of the atmosphere, B. HAUEWITZ (*Bull Amer. Met. Soc.*, 19 (1938), No. 10, pp. 417-424, fig. 1).—This is a review, with 16 references.

The vertical distribution of atmospheric ozone [trans. title], F. W. P. GÖTZ (*Ergeb. Kos. Phys.*, 3 (1938), pp. 253-325, figs. 51).—This monographic review of the subject (196 references) considers the advances in the principles and methods of reckoning and measuring ozone, determination of its vertical distribution, theories of its vertical distribution, and the results of such distribution, including its relations to ultraviolet radiation, to temperatures in the higher atmosphere, and to the weather.

Agricultural meteorology: Some characteristics of winds in Alberta and Saskatchewan, J. W. HOPKINS (*Canad. Jour. Res.*, 17 (1939), No. 1, Sect. C, pp. 4-24, figs. 7).—Over a period of years the monthly mean mileage of wind per day, April to September, at four meteorological stations in central and southern Alberta and Saskatchewan was greatest in April and May and least in July and August. The range of variations of the monthly means was considerable (order of 50 percent). Significant correlation in the interannual fluctuations at these stations was not demonstrable from the available data, but there was some indication of correlation between the mileages at a given station in successive months of the same year. Over the season as a whole northwesterly winds predominated, but in this respect too there were pronounced annual variations. Variation in the amount of wind from day to day within months was also pronounced, and tables show for each of the 6 mo. the relative frequency of occurrence of different daily mileages. On the whole, more wind was recorded during the day than the night. Hourly averages for all 6 mo. showed a definite diurnal trend, the maximum being around 3 p. m., but the actual hourly sequence on a given day might deviate markedly from this underlying regularity. There was a slight tendency for days of above-average temperature to have higher wind mileage, but this was a minor factor compared with the uncorrelated variation of both quantities.

Evaporation in agricultural meteorology, T. ALTY (*Canad. Jour. Res.*, 17 (1939), No. 1, Sect. C, pp. 1-3, figs. 2).—Data are presented emphasizing the fact that in order to relate the evaporation rate to other meteorological factors, the temperature of the evaporating liquid surface as well as that of the air must be known, and that the measurement of such temperatures at agricultural meteorological stations would be valuable. As the evaporation process itself cools the surface, its temperature is never equal to that of the liquid as a whole. It is suggested that a good approximation of the required surface temperature could be obtained by floating a thermometer horizontally in the surface of the liquid.

Industrial smoke drift and weather, H. H. LAMB (*Quart. Jour. Roy. Met. Soc. [London]*, 64 (1938), No. 277, pp. 639-643, figs. 2).—Local data from Scotland are presented as showing that drift from industrial smoke pollution of the air may give rise not only to fog but also to slight rain or drizzle and lowered cloud.

Recent tree-ring work in Alaska, J. L. GIDDINGS, JR. (*Tree-Ring Bul.*, 5 (1938), No. 2, p. 16).—It is concluded from this brief progress report on evidence of timberline trees that climatic conditions have been for several centuries uniform over the whole area from the Yukon River south to the Alaska Range.

The value of tree-ring analysis in engineering, R. LASSETTER (*Tree-Ring Bul.*, 5 (1938), No. 2, pp. 13-15).—The author reports briefly on several studies in northeastern Tennessee as showing the value of the tree-ring technic as an aid in hydrological problems, viz, adaptation of the technic to tree growth in the area, determination of the degree of relationship between tree growth and hydrological phenomena, when a suitable relation exists to compute the approximate precipitation and run-off from tree growth values as far back as the growth curve extends, and if possible to learn something of climatic trends in the area. It is concluded that the relationships derived from tree growth appear to be satisfactory enough to be of definite value in approximating past hydrological conditions.

February unusually wet—cold in West (*U. S. Dept. Agr., Weather Bur., Weekly Weather and Crop Bul.* 10 (1939), pp. 1, 2, figs. 2; also in *U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 23 (1939), No. 5, pp. 88-90, figs. 2).—Brief summaries of temperature and precipitation, with accompanying maps.

Meteorological observations (*Maine Sta. Bul.* 391 (1938), pp. 326-329).—The usual observations on temperature, precipitation, snowfall, sunshine, and wind at Orono for 1937 and the first 6 mo. of 1938 are summarized, and in addition corresponding data for 1937 for Presque Isle, Maine.

Meteorology report for State College, 1937, C. O. CROMER and C. A. KERN (*Pennsylvania Sta. Bul.* 367 (1938), pp. 65, 66).—A brief report on temperature and rainfall and snowfall, with a tabulated climatological summary for 1937.

The New England hurricane of September 21, 1938, R. M. BROWN (*Jour. Geog.*, 37 (1938), No. 8, pp. 293-300, figs. 6).—The author summarizes data on the path of the storm, the movement of water, damage by wind and by water, and recovery.

The effects of the hurricane upon New England forests, R. T. CLAPP (*Jour. Forestry*, 36 (1938), No. 12, pp. 1177-1181).—Although the greatest loss of life and the most spectacular property damage occurred along the New England coast, the most lasting scars were made on the forests, and the salvaging of some 4 billion feet of wind-thrown timber is said to be the gigantic task now presented. Some of the methods proposed for accomplishing it and the problems involved are here discussed.

Hurricane damage to Connecticut forests (*Forest Leaves*, 29 (1939), No. 1, pp. 9, 10, figs. 2).—This is a brief summary of the effects on wildlife and on timber and highway and shade trees, and of efforts under way for forest-fire protection and methods of salvage.

SOILS—FERTILIZERS

Work continued on fundamental soil studies (*Oregon Sta. Circ.* 180 (1938), pp. 6, 7, figs. 5).—This very brief general statement notes results obtained in soil surveys (coop. U. S. D. A.), studies of fertilizer requirements, and alkali reclamation.

[Soil investigations by the Alabama Station] (*Alabama Sta. Rpt. 1937*, pp. 12-16, fig. 1).—Lysimeter studies of nitrogen losses by leaching after soybeans, cowpeas, and crotalaria have been added to the soil are reported by J. R. Taylor, Jr., and J. W. Tidmore; the relation of soil types and the distribution of soils susceptible to boron deficiency by overliming, by J. A. Naftel; oxidation-reduction potentials of soils, by N. J. Volk; and elements required in small quantities for plant growth in soils, by A. L. Sommer.

[Soil investigations by the Iowa Station]. (Partly coop. U. S. D. A.). (*Iowa Sta. Rpt. 1938*, pts. 1 pp. 69-78; 2, pp. 9-19).—The report contains in part 1 notes on occurrence and activities of *Azotobacter* in Iowa soils as influenced by soil treatment, by A. G. Norman and W. Kubiena; utilization of carbonaceous materials by *Rhizobium*, decomposition of lignin in soils, and decomposition of some humus-forming materials in soils, all by Norman; decomposition of leguminous green manures in acid and limed soils, by F. B. Smith; relation between the free energy of soil water and the moisture content of soil, relation of capillary conductivity to the capillary tension and moisture content of soil, and factors determining the flow and distribution of water in soil and the development of field apparatus for soil moisture measurement, all by L. A. Richards; effect of various natural organic materials at different stages of decomposition on those physical and chemical properties of soils which affect erosion, by J. B. Peterson, Richards, and Kubiena; soil survey, soil conservation survey, land classification, and economic appraisal of the farm land in Tama County, by W. H. Pierre, T. H. Benton, B. J. Firkins, W. G. Murray, W. W. Wilcox, R. Finley, R. Schickele, and A. J. Englehorn; microscopic studies on soil erosion, by Peterson and Kubiena; and microbiological status of some Iowa soils as affected by water-logging and erosion, by Norman and Richards.

Part 2 includes studies on effects of fertilizers on crops and soil conditions under various rotations in the Wisconsin drift soil area, and effects of various amounts of fertilizers applied at different times in the rotation on crops and soil conditions in the Wisconsin drift soil area, both by Pierre and L. W. Forman; effects of various fertilizing materials on crop growth on the Carrington, Grundy, Tama silt loam, and some minor soils and on the chemical and bacteriological conditions in the soils, all by H. R. Meldrum and Englehorn; similar studies on the Clarion, Webster, and Marshall silt loam soils, by Meldrum; plant food content and lime requirements of Iowa soils and the composition of various crops, by Norman and Englehorn; soil erosion on the Marshall silt loam in Page County, Iowa, by Pierre, G. B. MacDonald, J. B. Davidson, and H. D. Hughes; and character, fertilization, and management of high lime and alkali soils of Iowa, by Pierre, Forman, and J. L. Boatman.

[Soil investigations by the Cornell Station] ([*New York*] *Cornell Sta. Rpt. 1938*, pp. 81, 82).—The report notes research work on the removal of certain constituents from soil in drainage water and in plants as influenced by nitrate of soda and sulfate of ammonia, respectively, and the accretion of nitrogen in soils under several cropping systems, both by J. A. Bizzell.

[Soil work by the Oklahoma Station] (*Oklahoma Sta. [Blen.] Rpt. 1937-38*, pp. 181-183, 189).—A test started in 1892 shows effects of lack of fertilizer. Phosphate fixation by clay minerals has been studied by H. F. Murphy.

[Soil investigations at the Pennsylvania Station] (Partly coop. U. S. D. A.). (*Pennsylvania Sta. Bul. 367 (1938)*, pp. 17, 18, 19, 21, 22, 23, 24).—The report contains brief notes on residual effects of fertilizers, by J. W. White, F. J. Holben, and C. D. Jeffries; test of phosphates, by C. F. Noll; "quick tests" of soils, by F. G. Merkle; mineralogical composition of Pennsylvania soils, by Jeffries and White; soil conservation, by N. R. Farris, R. D. Anthony, and E. W.

Schroeder; soil management studies in orchards, by Merkle and N. J. Shaulis; and nitrogen fixation in the soil, by White, J. J. Reid, Holben, and A. C. Richer.

[Soil investigations by the South Carolina Station] (*South Carolina Sta. Rpt. 1938, pp. 41-45, 131, 132, 150, 151, figs. 4*).—The effect of cropping practices on erosion and the run-off from different soil types are noted by T. C. Peele and F. Moser. Fertilizer placement is taken up by W. M. Lunn and J. B. Mattison (coop. U. S. D. A.). and lysimeter investigations by N. McKaig, Jr., and E. M. Roller.

[Soil investigations by the Texas Station]. (Partly coop. U. S. D. A.). (*Texas Sta. Rpt. 1937, pp. 20-22, 23, 24, 121-123, 176-179, 197, 198, 223-227*).—The following subjects are reported upon: Composition of soils and the relation of soil composition to plant and animal deficiencies, both by G. S. Fraps and J. F. Fudge; fertilizers affect composition of soils, by Fraps, Fudge, and E. B. Reynolds; the fixation of phosphate from dipotassium phosphate solution, by Fraps and P. Macy; and nitrification, by Fraps and A. J. Sterges.

Notes are given on a soil survey of Fannin County made by E. H. Templin et al.; of Dimmit County, by H. M. Smith et al.; and of Brown County, by W. I. Watkins et al.

Soil and water conservation investigations included experiments on soil and water losses, strip cropping, the effect of slope characteristics on soil and water losses, the effect of plant cover, burning woods, and terrace characteristics on soil and water losses, by J. B. Pope, O. C. Ward, and J. C. Acher. At the Temple Substation this work included general control plat work, terrace investigations, strip cropping investigations, and protection of eroded lands by revegetation, all by H. O. Hill. At the Spur Substation soil and water conservation studies were made with control plats, field areas, the sirup pan terrace system, pasture improvement, and buffalo grass selections, all by R. E. Dickson, B. C. Langley, and C. E. Fisher.

[Soil investigations by the Wisconsin Station] (*Wisconsin Sta. Bul. 442 (1938), pp. 59-61, fig. 1*).—These have been concerned with excretion of nitrogen from legume roots, role of bios, "hydrogen bacteria" and soil fertility, and vitamins for legume bacteria, all by P. W. Wilson, R. H. Burris, O. Wyss, P. M. West, S. Lee, and E. B. Fred.

[Soil Survey Reports, 1934 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1934, Nos. 12, pp. 41, figs. 5, map 1; 13, pp. 24, pls. 2, figs. 2, map 1*).—These surveys were made in cooperation with the respective State experiment stations: Nos. 12, Kitsap County, Wash., R. Wildermuth et al.; and 13, the Price area, Utah, F. O. Youngs and D. S. Jennings.

1 A method for obtaining a continuous measurement of soil moisture under field conditions, G. J. BOUYOUKOS and A. H. MICK. (Mich. Expt. Sta.). (*Science, 89 (1939), No. 2307, p. 252*).—The moisture content of a standardized block of CaSO_4 (gypsum) buried in the soil varies directly with that of the soil and may be measured by determining the electrical conductivity of the block by means of electrodes and a form of the Wheatstone bridge. A high degree of accuracy is reported.

Erosion and related land use conditions on the Elm Creek watershed, Texas, H. OAKES and E. SOMERVILLE (*U. S. Dept. Agr., [Soil Conserv. Serv.], 1939, pp. 20, pls. 5, fig. 1, maps 2*).—Conditions on this watershed, which comprises 159,195 acres all in farms, 84 percent cultivated, and affected by erosion damage ranging from slight to very severe, are described. The survey shows that 137,053 acres have been affected by accelerated water erosion, 50,442 acres slightly, 52,674 acres moderately, 20,200 acres severely, and 13,737 acres very severely eroded and essentially ruined for further cultivation. Control and recovery methods of the usual type are recommended.

The accuracy of the plate count of suspensions of pure cultures of bacteria in sterile soil, M. SUTHERLAND and N. JAMES (*Canad. Jour. Res.*, 16 (1938), No. 8, Sect. C, pp. 305-312, figs. 3).—A culture of *Pseudomonas fluorescens* was suspended in a sterile soil and water mixture. Dilutions of 1:2,000,000 and 1:10,000,000 were plated in four replicates of each dilution, nutrient agar being used. This was repeated 200 times. A χ^2 value was calculated from each set of four counts. The distribution of the 200 χ^2 values in the platings from each dilution agrees very well with the theoretical distribution. In a second experiment, 100 sets of four replicates of *P. fluorescens* were plated along with 100 of *Bacterium globiforme* and 100 of a mixture of the two cultures. The distribution of the χ^2 values in each of the three sets was such that the values could be considered to have been derived from populations distributed according to the Poisson series. The close conformity of the distribution of the actual χ^2 values to that of the expected in each of the five sets of data indicated that the mean of four replicates is reliable as an estimate of the population in the dilution plated, and further that the failure to obtain this conformity with soil flora is due to causes other than technic.

Effect of certain crops and soil treatments on soil aggregation and the distribution of organic carbon in relation to aggregate size, W. H. METZGER and J. C. HIDE. (Kans. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 30 (1938), No. 10, pp. 833-843, fig. 1).—Soil under growing corn and kafir in field and greenhouse showed as good aggregation under the sorghum crop as under corn. When oats succeeded these two crops in the field, however, soil samples from the oats stubble showed a greater degree of dispersion following sorghum than where corn was grown the preceding crop. Sweetclover left the soil better aggregated after 1 year's growth than did soybeans, while alfalfa and sweetclover gave similar results. Soil fallowed for 2 yr. in the field was less aggregated than soil fallowed for 1 yr. Limed soil under sweetclover and red clover in a greenhouse experiment was more highly aggregated than unlimed similar soil under these crops. Unlimed and unleached fallow soil in the greenhouse was as well aggregated as limed fallow soil. It is suggested that perhaps the combined action of lime and a legume crop, or possibly other crops, produces an aggregating force which lime alone does not exert. "The grasses failed to produce the aggregation of the soil expected of them, but their failure in this experiment may have been due to the shortness of the growth period."

Greenhouse soil management, E. C. STAIR. (Purdue Univ.). (*Ind. State Veg. Growers' Assoc.*, [Ann. Rpt.], 9 (1938), pp. 17-23).—This general discussion points out some advantages of a sandy soil for greenhouse vegetable growing and taking up methods of watering, prevention of "buckeye rot" by avoiding the splashing of soil onto leaves and fruit during watering, maintenance of organic matter supply, use of commercial fertilizers, sterilizing soils, etc.

Fertility studies on Dekalb soil and their application to farmland in Pennsylvania, J. W. WHITE, F. J. HOLBEN, C. D. JEFFRIES, and A. C. RICHER. (*Pennsylvania Sta. Bul.* 370 (1939), pp. [3]+48, figs. 12).—The area on which the plat experiments were located in Snow Shoe Township, Centre County, showed a weighted crop yields index of 76.6 compared to 94.8 percent for the average of the entire Dekalb farm land of the State. The experiments were started in 1916 and included 40 plats divided into 4 fields, 3 in a 4-yr. grain rotation and 1 in permanent pasture. The land was classified as submarginal land and had been abandoned for approximately 40 yr.

The economic returns indicated that this type of farm land is capable of profitable production under a system of farm management including the systematic use of lime, commercial fertilizers, and manure. In the production of pasture

grasses, the L+PKN treatment showed the maximum improvement. If L+PKN is expressed as 100 the relative returns were from L+P 66, from L+PK 88, and from L+MP 74. The relative crop-producing values of P, K, and N for the pasture plats were P 60, K 20, and N 20. The economic returns from 16 yr. of liming were similar in the case of limestone and hydrated lime. Based on the more economical fertilizer treatments previously indicated, the yields of crops at Snow Shoe were raised from a weighted crop yields index of 76.6 to a crop-producing value of 113 (the State average being taken as 100).

Results with potash in eastern Virginia, J. B. HESTER and J. M. BLUME. (Va. Truck Expt. Sta.). (*Better Crops With Plant Food*, 21 (1937), No. 6, pp. 9-12, 37-39, figs. 5).—The available potassium test is less convenient than those depending on color reactions but was found capable of separating soils into groups containing, respectively, 100 lb. or more, between 40 and 100 lb., and less than 40 lb. of readily available potash per acre. Both greenhouse and field plat tests supported, in general, the conclusions indicated by the cobaltinitrite turbidity test made on an extract obtained by the treatment of a soil sample with an acetic acid-sodium acetate solution buffered at pH 5.0.

Replacement of calcium in soils by sodium from synthetic irrigation water, G. S. FRAPS and J. F. FUDGE. (Tex. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 30 (1938), No. 10, pp. 789-796).—Calcium chloride and sodium chloride, in equal equivalent concentration and together equivalent to the exchangeable hydrogen in a hydrogen-saturated soil, replaced about 20 percent of the exchangeable hydrogen. Calcium absorbed represented about 75 percent of this quantity, and was thus three times as active as sodium in replacing hydrogen.

When 50 gm. of soil were shaken with 200 cc. of solutions containing 2.5, 5, 7.5, and 10 milligram equivalents of sodium chloride, the average net increase in calcium content of the solutions was equivalent to 36, 32, 30, and 30 percent, respectively, of the sodium originally present. The addition of 5 m. e. of calcium chloride to the solutions caused a decrease in net calcium of about 50 percent of that found in the solutions containing sodium chloride alone. When sodium bicarbonate was used instead of sodium chloride, the net calcium was very small and decreased with an increase in bicarbonate concentration.

Replacement of calcium from soil receiving a second shaking with solutions containing sodium chloride and calcium chloride was equal to about one-third that in the first shaking, while that in the case of soil shaken three times was less than one-fifth of that in the first shaking. A single shaking with a concentrated solution replaced about one-third more calcium than was replaced by the same quantity of salt applied in three shakings.

Calcium replaced by solutions containing 3.5 m. e. of sodium chloride and 0, 1.75, 3.5, 5.25, and 7 m. e. of calcium chloride was equivalent to 39, 28, 22, 18, and 14 percent, respectively, of the sodium chloride present. Calcium replaced by solutions containing 1.25 m. e. calcium chloride and varying quantities of sodium chloride per 100 cc. in six successive percolates represented 55, 31, 21, 11, 8, and 4 percent of the sodium chloride originally present.

Fertilizer-lime and crop rotation experiments, W. H. RANKIN. (N. C. Expt. Sta.). (*Com. Fert.*, 57 (1938), No. 5, pp. 8-10).—The author states some general results of long-period experiments at the Piedmont Substation.

Lime, while necessary for clover and beneficial for most legumes, increased the severity of cotton rust and of the "frenching" disease of corn when from 3 to 4 tons per acre were applied during 10 yr. The addition of 1 ton per acre every fourth year in a 4-yr. rotation gave the soil a poorer physical condition than that found where lime was not used. Nitrogen was needed for all crops in the rotation. Heavy phosphating or the use of phosphate with lime produced results similar to

those of overliming. Phosphates were needed, however. Continued application of potassium compounds only lowered the yields, but some potassium was needed to prevent the corn and cotton diseases mentioned. Complete fertilizers were more effective than incomplete mixtures or single fertilizer elements. Recommendations for specific crops on each of seven groups of Piedmont soils are offered.

Minor elements and major soil problems, L. G. WILLIS and J. R. PILAND. (N. C. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 30 (1938), No. 11, pp. 885-894, figs. 3).—"The perspective introduced into soil fertility experimentation by research on the functions of the so-called minor elements directs attention to the defects in the interpretations of prior work. The scientific objective of modifying single independent variables is demonstrated to be unattainable in fact even though it has been made the basis of all fertilizer experiments. The interpretations of such experiments are therefore subject to unavoidable errors, and practical applications derived from them are in some degree empirical. Recognition of this fundamental limitation constitutes the first step in increasing the efficiency of fertilizer usage. Further progress must depend upon accidental discovery or upon a more rational development of experimental procedure."

The minor elements in soil fertility and plant nutrition, W. L. POWERS (*Oregon Sta. Circ. Inform.* 192 (1938), pp. 5+[3], figs. 7).—A brief discussion of the possibilities of manganese, zinc, tin, boron, copper, and iodine in improving yields or preventing deficiency diseases is accompanied by description and illustration of some crop nutrition experiments with these elements.

The value of a ton of farm manure in the North Platte Valley, L. HARRIS. (Coop. U. S. D. A.). (*Nebraska Sta. Bul.* 318 (1938), pp. 20, figs. 2).—The rotation and manure experiments indicated a high residual value for manure, showing that heavy applications each year are not necessary to maintain yields at satisfactory levels. Good yields for a period of 25 yr. were obtained in a 6-yr. rotation of potatoes, oats, sugar beets, and 3 yr. of alfalfa, with a 12-ton application of manure to the sugar beet crop. It is estimated, on the basis of data on manure production by farm animals in the North Platte Valley, that the feed produced in this type of rotation is sufficient for the livestock required to produce the 2-ton per acre equivalent annual application of manure. Where a 4- or a 6-ton per acre annual application of manure is required for the whole area of a farm, as in 3-yr. and 2-yr. rotations, enormous numbers of livestock are needed to produce the required manure. Furthermore such rotations produce very little feed for livestock. The 6-yr. rotation, in which 50 percent of the land each year has been in alfalfa, has proved to be the most practical, from the viewpoint of a manure-livestock-feed relationship. It has also been found to be one of the most desirable rotations from the standpoint of the control of potato diseases.

Increases in the present population of livestock in the North Platte Valley ranging from 90 percent in 6-yr. rotations to 370 percent in 2-yr. rotations appeared to be necessary for the maintenance of the productivity of the soil on the basis of the rotation experiments.

AGRICULTURAL BOTANY

[Botanical studies by the Iowa Station]. (Partly coop. U. S. D. A.). (*Iowa Sta. Rpt.* 1938, pts. 1, pp. 109-112, 113, 114; 2, pp. 48-51).—In part 1, brief reports are given on studies of the structure of seed-coat and environal factors pertaining to germination of weed seeds, by J. N. Martin; distribution and ecology of plants in the waterfowl breeding areas of Iowa, by A. Hayden;

and the relation of plant cover to erosion control, by J. M. Aikman and A. F. Dodge.

In part 2, brief reports are included on a comparative study of the stem and root development of some of the varieties of field corn grown in Iowa, as to the anatomical features manifested at successive stages of development, by Martin; translocation gradients in the corn plant and their relation to photosynthesis and yield, by W. E. Loomis; and measurement of the limiting environmental factors in the growth of the corn plant at different rates and spacings, by Aikman.

[Botanical studies by the Cornell Station] ([*New York*] *Cornell Sta. Rpt.* 1938, pp. 100, 101, 102, 110).—Progress reports are included on stomatal behavior and rate of photosynthesis in strains of corn, by O. F. Curtis, D. G. Clark, J. I. Shafer and R. A. Emerson; translocation of solutes in plants—tissues concerned in translocation and factors influencing the rate and direction of movement, by Curtis and R. Shurtleff; requirements for the storage and germination of seeds of various aquatic plants, by W. C. Muenscher and O. L. Justice; and influence of X-rays on the growth and metabolic processes in ferns, by L. Knudson and G. R. Mandels; and bacterial physiology and fermentation, by O. Rahn and J. M. Sherman.

Advances in botany, edited by F. VON WETTSTEIN (*Fortschritte der Botanik. Berlin: Julius Springer, 1938, vol. 7, pp. IV+339, figs. 23*).—Surveys are included of the literature in the fields of morphology, systematics and phylogeny, physiology of metabolism, physiology of organ formation, and ecology.

Plant form and function, F. E. FRITSCH and E. J. SALISBURY (*London: G. Bell & Sons, 1938, pp. VIII+668, figs. 445*).—As the title implies, this textbook, intended not only to cover the first year university syllabus but also to provide an adequate foundation for a nonspecialized graduate course, includes the fundamental knowledge regarding morphology and anatomy and also the physiological and ecological aspects of plant life. There is a chapter on the British flora, and brief accounts of additional families are introduced to include all those to which frequent reference is made in the text. An especially adequate index is included.

The structure of economic plants, H. E. HAYWARD (*New York: Macmillan Co., 1938, pp. X+674, pl. 1, figs. 340*).—In this book the available data have been freely drawn upon, and selected literature citations appear at the conclusion of each chapter. The material is organized in two parts, viz, general plant anatomy, and the structure of a selected number of economic plants representing 13 families (corn, wheat, onion, hemp, beet, radish, alfalfa, pea, flax, cotton, celery, sweetpotato, potato, tomato, squash, and lettuce). A glossary and an index are provided.

Introduction to the botany of field crops.—I, Cereals. II, Non-Cereals, J. M. HECTOR (*Johannesburg: Cent. News Agency, Ltd., [1936], vols. 1, pp. XXXIV+478, figs. 190; 2, pp. XXXIII+479-1127, figs. [258]*).—This monographic text presents and copiously illustrates anatomical data on the roots, stems, leaves, and inflorescences of the plants included, their sex expression and pollination, organization of the ovule and fertilization, the fruit and seed, chromosome numbers and behavior, classification, and other general information. Keys are provided, bibliographies terminate the chapters, and each volume is provided with author, plant, and general indexes. Volume 1 includes members of the Gramineae (the small grains, millets, sugarcane, sorghums, and maize), and volume 2 members of the Liliaceae (onions and asparagus), Moraceae (hemp and hops), Polygonaceae (buckwheat family), Chenopodiaceae (beet family), Cruciferae, Leguminosae, Linaceae (flax), Malvaceae (cottons), Umbelliferae,

Convolvulaceae (sweetpotato), Solanaceae (potato, tomato, tobacco), Curcubitaceae, and Compositae.

Botanical dictionary, F. SAFTENBERG, rev. by F. HEILIG (*Botanisches Wörterbuch*. Leipzig: Hachmeister & Thal, 2. ed., rev., pp. 176).—The taxonomic position, derivation, and common names are indicated for generic and species names, with accent indicated. A separate index to German common names is also provided.

Selected list of references on microbiology, compiled by H. F. SMART (*U. S. Dept. Agr., Bur. Chem. and Soils, 1938, pp. 5*).—Books are listed under eight categories, viz, general and systematic, medical, industrial and agricultural, and veterinary bacteriology, laboratory methods, microbiology of foods, yeasts and molds, and microbiological books dealing with bacterial chemistry and metabolism.

Submicroscopic morphology of protoplasm and its derivatives, A. FREY-WYSSLING (*Submikroskopische Morphologie des Protoplasmas und seiner Derivate*. Berlin: Borntraeger Bros., 1938, pp. XIV+317, figs. 133).—The subject matter is discussed under the principles involved, including the theories of phase, structure, and micelles; the minute structure of protoplasm, including the cytoplasm, nucleus, and chloroplasts; and the minute structure of plasma derivatives, including structural elements and reserve materials.

Fundamental principles of bacteriology, with laboratory exercises, A. J. SALLE (*New York and London: McGraw-Hill Book Co., 1939, pp. XIII+679, figs. 215*).—This is a general textbook on bacteriology, including the yeasts, molds, and viruses, with chapters on microbiology in agriculture and industry and in relation to diseases in plants, animals, and man.

An introduction to industrial mycology, G. SMITH (*London: Edward Arnold & Co., 1938, pp. XII+302, figs. 127*).—In this textbook sufficient general mycology is included to orient the student, but the major portion consists of descriptions and illustrations of most of the genera of molds which occur regularly in industrial products, with more detailed consideration of the most important genera. Six chapters deal directly with the main taxonomic groups of molds, while single chapters concern laboratory equipment and technic, physiology of mold fungi, maintenance of a culture collection, control of mold growth, and industrial uses of fungi, respectively. Literature references terminate the individual chapters, while a chapter is devoted to the general mycological literature, and an index is provided. The foreword is by H. Raistrick.

The occurrence of mycorrhizae, considered systematically, with special reference to the extent of our knowledge concerning them, A. P. KELLEY (*Landenberg, Pa.: Landenberg Lab., 1938, pp. 12*).—The author presents a synopsis of mycorrhizal angiosperms, gymnosperms, and pteridophytes, pointing out the limitations of our knowledge of mycorrhizas and indicating where it might be widened.

Respiration and lactic acid production by a fungus of the genus *Rhizopus*, S. A. WAKSMAN and J. W. FOSTER (N. J. Expt. Stas.). (*Jour. Agr. Res. [U. S.]*, 57 (1938), No. 12, pp. 873-899, figs. 5).—In general, conditions favoring growth of the *Rhizopus* used proved unfavorable to the accumulation of lactic acid. The fully grown pellicle in a sugar solution produced lactic acid up to 50 percent of the sugar under anaerobic and to ± 60 percent under aerobic conditions, some growth accompanying the process in the latter case. Only $\pm 30-40$ percent of the carbohydrate consumed was changed to the acid in the absence of a neutralizing agent, in growth cultures, and as much as 70-75 percent in its presence. It is thus concluded that the fungus produces lactic acid by a fermentation mechanism despite its strictly aerobic nature. The acid is preceded by an intermedi-

any substance, converted by the pellicles under anaerobic conditions to the extent of 50 percent to the acid and the remaining portion to alcohol and CO₂, with the liberation of only a little energy. During growth or under aerobic conditions the lactic acid and alcohol precursors are oxidized partly to the acid and partly to CO₂. The presence of different elements influences which reaction shall predominate, e. g., zinc favors growth and is unfavorable to lactic acid production, while the reverse influences are exerted by iron. *Rhizopus* is thus shown to possess both fermentative and oxidative mechanisms, resembling those of higher forms of life.

Element assimilation by plant life, with reference abstract bibliography: A contribution to the literature on agronomy, G. H. RIDDLE (*Res. Found., Inc.*, [1938], pp. [183], figs. 47).—This monograph on the phenomenon of element assimilation by plant life—which the author concludes to be due to specific physical, chemical, and electrokinetic forces coordinating to either buffer or accelerate their several functions—is described by the author as “a technical paper designed to clarify the general conception as to the functions of any specific plant in employing selective (or elective) dialysis as regards the quantity of any element, or the ions of such element, which it utilizes from the soil solutions. Such quantity, under conditions normal to the healthy plant having been designated by the author as the ‘Saturation Constant Specific to the Plant.’” The reference abstract bibliography contains a large number of references, and author and subject indexes are provided.

Effects of a limiting element on the absorption of individual elements and on the anion : cation balance in wheat, A. G. McCALLA and E. K. WOODFORD (*Plant Physiol.*, 13 (1938), No. 4, pp. 695–712, figs. 5).—Limiting the supply of one nutrient resulted in an increased uptake of another absorbed as an ion of the same sign, or in a decreased total uptake of the nutrients absorbed as ions of opposite sign. With N limiting, the effect was chiefly felt in increased P absorption, although there was also in some cases an increased S absorption. In one series of graded N and P supply, the increased P absorption resulting from limiting N supply was fully equivalent to the decreased N uptake. Limiting K was accompanied by increased absorption of both Ca and Mg. Limiting Ca was accompanied by relatively increased absorption of K and Mg and slightly decreased absorption of anions. In spite of relatively enormous differences in ratios of individual nutrients as a result of limiting one of them, there was a marked tendency toward maintaining a balance between total anions and cations—this balance always being in favor of the anions.

The effect of drops of water on leaf temperatures, P. J. KRAMER (*Amer. Jour. Bot.*, 26 (1939), No. 1, pp. 12–14, figs. 2).—Temperatures of sprayed leaves of six different kinds of plants as measured by copper-constantan thermocouples inserted into the leaves, both under a 500-w. tungsten lamp and exposed to the sun, were 4°–12° C. less than corresponding unwet leaves. The focal point of drops of water on the leaf surface was found to be usually greater than the leaf thickness, rendering doubtful the commonly reputed injury to leaves from exposure to sun while water drops are present.

Stomatal index and transpiration rate of leaves, H. B. SMITH (*Science*, 89 (1939), No. 2308, pp. 268, 269).—The author presents observations on beans supporting the view that juvenile leaves may be advantageously used to compare plants in breeding work dealing with transpiration rate, and that transpiration rate is associated with stomatal index rather than with stomatal number. This index may be determined from any of the leaves of a young bean plant.

Quantitative isolation of chloroplasts from higher plants, S. GRANICK (*Amer. Jour. Bot.*, 25 (1938), No. 8, pp. 558–561).—By this method, using tomato

and tobacco leaves, the cells were torn apart by grinding under hypertonic sugar solutions, and the chloroplasts were separated from the other cell materials by differential centrifuging. A method is also presented for relating the quantity of chloroplasts isolated to the total quantity in the leaf sample, based on the assumption that the number of chloroplasts is directly proportional to the quantity of contained pigments.

Chloroplast nitrogen of some higher plants, S. GRANICK (*Amer. Jour. Bot.*, 25 (1938), No. 8, pp. 561-567, fig. 1).—Methods are described for determining the nitrogenous constituents of the chloroplasts as compared to the remainder of the protoplasm during the development and aging of leaf parenchyma cells of tomato and tobacco, the chloroplasts being first removed as described in the preceding paper. The nitrogen fractions of the chloroplasts analyzed consisted of a crude-lipid fraction soluble in alcohol-ether, a protein fraction insoluble in 7 percent trichloroacetic acid, and a soluble rest-nitrogen. The nitrogen of the chloroplasts increased with the nitrogen of the rest of the protoplasm, and in these two plants contained 30-40 percent of the total nitrogen of the leaf blade material outside the midrib and main veins. The protein of the chloroplast constituted 80 percent of the chloroplast nitrogen, and chlorophylls a+b accounted for another 10 percent. In the average leaf parenchyma cell it was estimated that 35-45 percent of its protein was contained in its chloroplasts. A parenchyma cell at two-thirds its maximum attainable size contained ± 10 times more total nitrogen and protein nitrogen than a cell one-third its maximum size, while the nitrogen of the fully expanded cell was only 25 percent greater than that of the cell at two-thirds its maximum size. The evidence suggests that the chloroplasts as well as the nonchloroplast protoplasm have the ability to synthesize their own proteins. Assuming a molecular weight of 100,000 for the proteins of the chloroplast, it is estimated that there are ± 30 chlorophyll molecules for each protein molecule of the chloroplast.

Influence of photoperiod and other factors on the formation of flower primordia in the potato, H. A. JONES and H. A. BORTHWICK. (U. S. D. A.). (*Amer. Potato Jour.*, 15 (1938), No. 12, pp. 331-336, fig. 1).—In potato the first inflorescence was differentiated at approximately the same node under a range of temperature, photoperiod, size of seed piece, etc. The small size of seed piece (5 gm.), the high temperature (day 80° and night 55° F.), and the short photoperiod (9 hr.) tended to increase the node number to the first inflorescence. Flower primordia were differentiated in darkness.

The time course of photosynthesis as shown by the glass electrode, with anomalies in the acidity changes, L. R. BLINKS and R. K. SKOW (*Natl. Acad. Sci. Proc.*, 24 (1938), No. 10, pp. 413-419, figs. 4).—The glass electrode method described is believed to have value in indicating the direction and the relative speed of photosynthesis during the first moments of illumination. It is further believed that the anomalies are not artifacts, since obvious controls with dead tissue, green cellophane, black paper, agar, or the blank electrode failed to show any significant response to light. Infrared was largely filtered out, and when used alone it gave only a slow drift due to heating, quite different from the cusps in visible light.

The time course of photosynthesis as shown by a rapid electrode method for oxygen, L. R. BLINKS and R. K. SKOW (*Natl. Acad. Sci. Proc.*, 24 (1938), No. 10, pp. 420-427, figs. 5).—Application of the glass electrode in direct contact with plant cells or tissues (see preceding entry) proved so valuable in following rapid CO₂ changes during and after illumination that a corresponding method for following oxygen evolution and consumption was worked out and is described and compared. It is believed that this method may give a valu-

able correction to apply in determining the true photosynthetic rate for quantum efficiency and other determinations.

Effect of ultraviolet radiation on plants, H. W. PORR (*Pennsylvania Sta. Bul.* 367 (1938), pp. 32, 33, 34).—Note on the effects of different wavelengths on growth substance and development of plants.

The Mirsky-Pauling theory of the structure of native, denatured, and coagulated proteins, and some theoretical aspects of the evolution of oxygen from the irradiated green plant, O. L. INMAN (*Plant Physiol.*, 13 (1938), No. 4, pp. 859–862).—This review and discussion calls attention to some possible relationships which may exist between the sensitization and denaturation of proteins and one phase of the mechanism of photosynthesis. Although there seems to be no good reason for assuming that visible radiation directly activates either CO₂ or water, it is deemed to be certainly possible that water or CO₂ or a combination of the two, when associated with chlorophyll which does absorb visible radiation, might become activated and enter into chemical and photochemical reactions one of which could be the release of oxygen.

The metabolism of proteins in green leaves, H. B. VICKREY (In *Cold Spring Harbor Symposia on Quantitative Biology*, VI. Cold Spring Harbor, N. Y.: Biol. Lab., 1938, vol. 6, pp. 67–78, figs. 6).—This is a critical analytical review of the present status of knowledge (33 literature references), including the findings of the author and his associates.

Preliminary experiments on biotin, W. J. ROBBINS and M. B. SCHMIDT (*Bul. Torrey Bot. Club*, 66 (1939), No. 3, pp. 139–150, fig. 1).—Based on its effect on the growth of *Ashbya gossypii* (method described), the amount of biotin found in a sample of liquid manure was $150,000 \times 10^{-8}$ γ per gram of dry weight, while unfiltered sirup, cerophyl, and egg yolk contained ± 600 units and other substances tested smaller quantities. The amount decreased with the purity of the sugar samples tested. Neither pantothenic acid nor vitamin B₆ were found to replace biotin.

The influence of certain growth-promoting substances on the rooting of some southern ornamental plants, E. W. McELWEE. (Ala. Expt. Sta.). (*Assoc. South. Agr. Workers Proc.*, 39 (1938), pp. 110, 111).—An abstract.

An assay method for growth-promoting substances utilizing straight growth of the Avena coleoptile, R. L. WENTRAUB (*Smithson. Misc. Collect.*, 97 (1938), No. 11, pp. [1] + 10, pl. 1, fig. 1).—The assay method here described for growth-promoting substances, utilizing straight growth of the oat coleoptile, is believed to possess a number of theoretical and practical advantages over the widely used curvature test.

- **Carbohydrates of bean plants after treatment with indole-3-acetic acid**, T. R. ALEXANDER (*Plant Physiol.*, 13 (1938), No. 4, pp. 845–858, figs. 7).—When the stem ends of beans were removed above the primary leaves and the stumps treated with 2 percent indole-3-acetic acid-lanolin, tumors and roots developed at the point of treatment, but the final dry weight was greater in the control than in the treated plants. Carbohydrates were translocated toward the point of treatment, but the final amount of starch was greater in the untreated controls. Indole-3-acetic acid stimulation induced conditions causing simple carbohydrates to be condensed to complex polysaccharides at the point of application. Losses in dry weight of the treated plants are said to indicate respiratory increases. Reduction of soluble carbohydrates in the treated stem ends was caused by increases in acid-hydrolyzable substances, and probably also by respiration incident to the stimulated metabolic activity of the tumor.

The dual effect of auxin on root formation, F. W. WENT (*Amer. Jour. Bot.*, 26 (1939), No. 1, pp. 24–29, fig. 1).—Using etiolated pea stem cuttings which

are relatively free from auxin, it was shown that phenyl acetic acid is not in itself a root-forming substance. Although redistribution of rhizocaline was tentatively considered the immediate effect of this material and several other substances, including indole acetic acid, it is suggested that the latter and related substances can induce root formation subsequently by activation of the accumulated rhizocaline.

After-effects of the treatment of seed with auxin, K. V. THIMANN and R. H. LANE (*Amer. Jour. Bot.*, 25 (1938), No. 7, pp. 535-543, figs. 8).—Using *Avena* and *Triticum*, low auxin (indole-3-acetic acid) concentrations accelerated the rate of root elongation while high concentrations inhibited it. However, if the auxin was removed the growth of the inhibited roots became faster than that of the controls, so that in a few days the treated roots were considerably longer. Furthermore, high auxin treatment increased the number of roots on the young plants. After such treatment with high auxin concentrations the general vegetative growth of the shoot is accelerated, the leaves may become longer and wider, and the dry weight of the plants may be increased more than 50 percent. Flowering is also slightly hastened. This general acceleration is considered an aftereffect, due to the action of auxin on the root system. If auxin treatment of *Avena* is delayed until the seedlings are 24 hr. or more old the length of the first leaf is decreased, while in *Triticum* this result follows both the delayed treatment and treatment of the seed. Growth of later leaves is nevertheless hastened. Vernalization brings about the same results in *Triticum*. It is therefore tentatively suggested that the vegetative effects of vernalization are due to the prolonged exposure of the seed to its internal auxin supply.

Nicotinic acid and the growth of isolated pea embryos, J. BONNER (*Plant Physiol.*, 13 (1938), No. 4, pp. 865-868).—Evidence is presented that nicotinic acid, known to be a component of the vitamin B complex and to be indispensable to the growth of certain micro-organisms, is also a growth factor for pea seedlings. Its general distribution or that of closely related derivatives in natural plant products leads to the tentative conclusion that its function is also widespread in the higher plants.

Synthesis carried out in vivo by isolated pea roots, I, J. BONNER and E. R. BUCHANAN (*Natl. Acad. Sci. Proc.*, 24 (1938), No. 10, pp. 431-438).—Under closely controlled environment and nutrient supply it is shown that the isolated pea root synthesizes vitamin B₁ or something indistinguishable from it by *Phytophthora* assay from a mixture of the pyrimidine and thiazole components of the vitamin molecule, and that this reaction is carried out in vivo under conditions such that no in vitro reaction can occur. This must be a synthesis in which a specific enzyme takes part. A second and distinct enzyme system is able to effect closure of the thiazole ring from suitable acyclic substances to form the vitamin thiazole. It is suggested that both "thiaminase" and "thiazolase" play their parts in the natural synthesis of thiamin by the plant. It was further shown that certain thiazole derivatives are transformed to the vitamin thiazole in vivo by enzymatic reactions corresponding to deamination, decarboxylation, hydrolysis, and hydration, whereas certain other growth-promoting thiazoles are not so transformed. It is suggested that the methods outlined may offer a new and more exact approach to the problem of the mechanism of biosyntheses.

Thiamin (vitamin B₁) and the growth of roots: The relation of chemical structure to physiological activity, J. BONNER (*Amer. Jour. Bot.*, 25 (1938), No. 7, pp. 543-549, figs. 2).—The root tips, as excised from seedling peas, are found to contain a considerable "reserve" of thiamin. Thus thiamin does

not limit root growth in vitro until the roots have grown 60 mm. or more and tips of these roots have been transferred to fresh medium. The pea root utilized an equimolar solution of the pyrimidine and thiazole portions of the thiamin molecule, and it is deemed probable that these two portions are synthesized in vivo to the vitamin molecule itself. The pea root utilized a considerable number of substituted thiazole compounds. It was found essential, however, that a hydroxyl group (or one readily metabolizable to it) be present in the molecule if the substance is to possess growth-factor activity for roots. Quaternary salts, unless the substituent possessed the prerequisites of an active pyrimidine, could not be utilized. "As the pyrimidine constituent the root can utilize 2,5 dimethyl, 6 amino pyrimidines, substituted in the 5 methyl position by groups which will permit of the formation of quaternary salts. The 6 amino group cannot be replaced by a hydroxyl group."

A plant growth inhibitor, W. S. STEWART, W. BERGREN, and C. E. REDEMANN (*Science*, 89 (1939), No. 2304, pp. 185, 186, figs. 2).—The ether extract of cotyledons of French Breakfast radish yielded by the simplified method of Van Overbeek (*E. S. R.*, 79, p. 313) a substance producing on *Avena* effects opposite in character to those produced by indole-3-acetic acid.

Plant indicators—concept and status, A. W. SAMPSON. (Univ. Calif.). (*Bot. Rev.*, 5 (1939), No. 3, pp. 155–206, figs. 2).—From this comprehensive review of a large literature (142 references) it is deemed evident that there are many kinds of plant indicators, and the consensus of opinion is that communities of plants are more reliable in indicating the character of the habitat than are individual species. Although experienced field workers often make use of plant indicators in various ways, there is as yet no recognized technic for selecting them. Applications to land-use problems, including forestry, and to grazing lands are discussed especially. It is concluded that a broader use of indicator communities and species is likely, but there must first be a more critical study of the growth requirements of both the indicator and the economic species before the method will reach its maximum reliance.

Notes on the genus *Ribes* in California, C. R. QUICK. (U. S. D. A.). (*Madroño*, 4 (1938), No. 8, pp. 286–290, pl. 1).—In the course of field work in the control of white pine blister rust, field supervisors have made interesting observations on the distribution and morphology of native *Ribes* species. The notes here presented include the more important of those observations not hitherto recorded.

The anatomical development of *Lepidium draba*, A. O. SIMONDS. (Colo. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 57 (1938), No. 12, pp. 917–928, pls. 4, figs. 5).—This investigation of the anatomical development of hoary cress from seed to maturity deals with one of the most persistent perennial weeds in the West. It takes up the seedling morphology; the anatomy of the embryo; the root, including the structure of the xylem, phloem, and cortex; the root-stem transition; the stem, including the primary structures and changes in the mature stem; the crown; adventitious shoot and root formation; and the leaf. Details are presented and illustrated.

Influence of culture conditions upon the growth and development of *Dictyostelium discoideum*, K. B. RAPER. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 3, pp. 157–198, figs. 10).—Continuing the culture studies of this slime mold of the soil (*E. S. R.*, 78, p. 202), a medium containing 1.2 percent each of peptone and a carbohydrate easily fermented by the associated bacteria was found to provide an especially favorable substrate for growing the host bacteria (*Escherichia coli* and *Pseudomonas fluorescens* used) and for the subsequent growth and normal development of the *Dictyostelium*. In the absence

of a fermentable carbohydrate the colonies of host bacteria became alkaline and toxic to the slime mold. The optimum reaction for the latter was pH 6-6.5, while good growth and normal fruiting structures occurred regularly on bacterial colonies at pH 5-7. The myxamoebae failed to feed effectively on bacterial cells encased in gum or slime, although such colonies were wholly non-toxic to the slime mold. More nearly optimum conditions were required for development of the fruiting structures than for vegetative growth, and in turn the requirements were stricter for normal than for abnormal sorocarp development. In fact, the sorocarp pattern served as a useful basis of judgment as to the favorableness of cultures to this organism. The bibliography contains 28 references.

Temperature effects upon the growth of excised root tips, G. C. GALLIGAR (*Plant Physiol*, 13 (1938), No. 4, pp. 835-844, fig. 1).—The optimum temperature for excised pea roots was found to be 10° C., for sunflower and corn 20°, and for cotton 25°. Few lateral roots or none developed at 10° and 35°. Anthocyanin formation in corn was inhibited at 25° and 35°, while 10° and 15° retarded pigmentation in cotton. Marked distention in diameter occurred in pea roots at 10° and 25°, and in corn and sunflower roots at 35°. For the growth of root tips of all four plants, 35° was definitely beyond the range of optimum temperature.

A method for the culture of excised plant parts, R. F. DAWSON (*Amer. Jour. Bot.*, 25 (1938), No. 7, pp. 522-524).—By the method described, leafy shoots of tobacco were cultured in solutions containing organic substances, decomposition of which was practically prevented by chilling the cultures to 5°-10° C. Several external factors apparently influencing the success of cut stem and excised leaf cultures are discussed.

Pollen longevity of Ginkgo, E. H. NEWCOMER. (Mich. State Col.). (*Bul. Torrey Bot. Club*, 66 (1939), No. 2, pp. 121-123, figs. 4).—An experiment is reported in which the pollen maintained its viability for a period of nearly 16 mo.

GENETICS

Principles of genetics, E. W. SINNOTT and L. O. DUNN (*New York and London: McGraw-Hill Book Co.*, 1939, 3. ed., pp. XIV+408, [pl. 1], figs. 147).—This revision (E. S. R., 54, p. 427) has been largely rewritten to incorporate the advances in the development of genetics which take account of progress in gene location by studies of large salivary chromosomes of some insects, induction of mutations by radiation, contributions of transplantation of tissues to physiological action of the gene, and other related developments.

What are the genes?—II, The physico-chemical picture: Conclusions, A. GULICK. (Univ. Mo.). (*Quart. Rev. Biol.*, 13 (1938), No. 2, pp. 140-168, figs. 7).—Continuing these studies (E. S. R., 79, p. 610), genes are concluded to unite characteristics that render an organism capable of metabolism and amenable to the biological type of evolutionary processes. The number, size, and composition of genes suggest that they are essentially living units consisting either of a single large molecule or a cluster of molecules of nucleic acid and nitrogen-rich amino acids. Two types of action are attributed to genes. One is autocatalytic, permitting formation of further similar molecules, and the second is an enzymelike control over cytoplasmic happenings. Chemical alteration in the gene results in mutations. The haploid gene numbers were estimated as between 2,000 and 13,000 for *Drosophila* and 6,600 and 78,000 for man.

Spragg memorial lectures on plant breeding (*East Lansing: Mich. State Col.*, 1937, pp. 86; 1938, pp. 16).—The lectures in this series include Contribution of Plant Breeding to the Agriculture of the United States, by H. H. Love

(pp. 5-16), and Heredity and Environment, by R. A. Emerson (pp. 33-41) (both Cornell Univ.); New Crops for Old, by T. A. Kiesselbach (pp. 17-32) (Univ. Nebr.); Disease Resistance in Crop Plants, by J. H. Parker (pp. 42-48) (Kans. State Col.); The Role of Plant Breeding in Crop Improvement, by H. K. Hayes (pp. 49-56) (Univ. Minn.); The Life and Work of Luther Burbank, by D. F. Jones (pp. 57-76) (Conn. [New Haven] Expt. Sta.); Improvement of Pasture Grasses and Legumes, by L. E. Kirk (pp. 77-86); and Corn Breeding Experience and Its Probable Eventual Effect on the Technique of Livestock Breeding, by H. A. Wallace (pp. 3-16) (U. S. D. A.).

Radiation and plant cytogenetics, T. H. GOODSPEED and F. M. UBER. (Univ. Calif. and Univ. Mo.). (*Bot. Rev.*, 5 (1939), No. 1, pp. 1-48).—The subject is reviewed (326 references) under the headings: Introduction and historical summary, physical nature of biological effects of radiation (X-rays, alpha particles, neutrons, and electrons including cathode and beta rays), types of material irradiated, types of induced alteration, and cytogenetic consequences of chromosomal alterations.

Effect of the *Dt* gene on the mutability of the *a₁* allele in maize, M. M. RHOADES. (U. S. D. A.). (*Genetics*, 23 (1938), No. 4, pp. 377-397, figs. 5).—Further studies (E. S. R., 77, p. 175) showed that the *a₁* allele (dotted aleurone), which has a low spontaneous mutation rate in the presence of recessive *dt*, becomes highly mutable with dominant *Dt*, the mutation frequency being proportional to the dosage of the *a₁* gene. Mutations of *a₁* to the *A₁* allele occur about 1,000 times as frequently as to the *a₂* allele. Mutations of *a₁* occurred in aleurone, culm and sheaths, and pericarp, and there were indications that they occur late in the development of each tissue and not consonantly in all parts of the plant. The existence of a dominant modifying gene which decreases mutation frequency was indicated. The *a₁* and *Dt* genes are not linked; *a₁* is in chromosome 3, and *Dt* may be in chromosome 9. The data did not support the view that mutations of *a₁* induced by *Dt* result from a position effect; *Dt* remains unaltered when a mutation of *a₁* takes place. Cytological observations of the *Dt* and *dt* stocks showed no evidence of gross chromosomal aberrations.

Induction of polyploidy in *Nicotiana* by hetero-auxin treatment, W. H. GREENLEAF. (Univ. Calif.). (*Jour. Heredity*, 29 (1938), No. 12, pp. 451-464, figs. 8).—Using indole-3-acetic acid, plants of several species and species hybrids of *Nicotiana* were made to regenerate plentifully. Two *F₁* hybrids in particular were employed in the tests reported, viz, *N. sylvestris-tomentosiformis* and *N. sylvestris-tomentosa*. Enormous calluses were in many cases formed and hundreds of shoots were obtained from them. These plants failed to regenerate without heteroauxin. Treatment resulting in shoot formation in *Nicotiana* inhibited such results on callus of tomato plants. In 1,973 classified shoots of the two hybrids above named the frequency of tetraploid shoots was 13.7 percent. Also ± 30 octoploid and 5 different heteroploid shoots occurred. The allo-octoploid types with 96 chromosomes showed great deviation in morphology as compared with corresponding diploids and tetraploids. A general decrease in plant size was correlated with general monstrosity in the *8n* plants. The changes went beyond the usual quantitative deviations from parental form observed in polyploids in general. The theoretical behavior of tetraploids on inbreeding is considered on the basis of random chromosome and chromatid segregation in the simplex, duplex, and triplex, and the expected proportions of homozygosis are calculated up to five generations.

Somatic variation of chromosome numbers in hybrid wheats, R. M. LOVE (*Genetics*, 23 (1938), No. 6, pp. 517-522, pl. 1).—Pollen mother cells with aberrant chromosome numbers ranging from 15 to 61 and bivalent chromosomes

varying from 3 to 29 were found in 16 of 336 plants of 50 *vulgare*-like lines derived from interspecific crosses involving 4 varieties of *Triticum vulgare* and Tumble (T. durum).

Cytology of poplar species and natural hybrids, F. H. Peto (*Canad. Jour. Res.*, 16 (1938), No. 11, Sect. C, pp. 445-455, pl. 1, figs. 6).—Of five species and two species hybrids examined at the first metaphase of pollen mother cell formation, *Populus alba* and two of four *P. canescens* trees were found to be triploid, while all others were diploid. Pollen characters, such as percentage of good pollen, pollen diameter, and pollen-size distribution, were generally not indicative of chromosome number or pairing relations at first metaphase. The tendency for the poplars to produce unreduced pollen grains is believed to explain the number of triploid trees discovered in Canada and Sweden.

Intergeneric hybridization.—A preliminary note of investigations on the use of colchicine in inducing fertility, A. R. RAW (*Jour. Dept. Agr. Victoria*, 37 (1939), No. 1, pp. 50-52, figs. 3).—The successful induction of complete fertility in the normally totally sterile intergeneric hybrid *Triticum vulgare* × *Agropyron intermedium* by the action of colchicine is reported.

The breeding of new yeast types through hybridization, O. WINEE (*Bakers Tech. Digest*, 13 (1939), No. 7, pp. 123-125, figs. 9).—A popular discussion of progress in this field.

The nature and origin of filtrable viruses, C. C. LINDEGREN (*Jour. Heredity*, 29 (1938), No. 11, pp. 409-414).—This theoretical consideration relates the bacteriophage and other filtrable viruses to the gene, and postulates that the cooperation of genes and cytoplasm may depend on two restrictive devices, viz, the chromatin envelope of the gene which prevents contact of gene and cytoplasm at mitosis and the nuclear membrane which prevents contact of the more or less exposed resting-stage genes and the cytoplasm. Free genes and cytoplasm may be antagonistic because the cytoplasm may contain gene-inactivating antibodies, and genes in direct contact with cytoplasm (if not inactivated by antibodies) might divide without restraint and destroy the cytoplasm together with the food stored in it. It is assumed that the interposed chromosomal and nuclear membrane in ordinary living forms make it possible for the genes to transform and direct the energy supplied by the cytoplasm.

[Research in animal genetics and breeding at the Iowa Station], J. L. LUSH, C. Y. CANNON, E. N. HANSEN, P. S. SHEARER, C. C. CULBERTSON, M. D. HELSER, F. J. BEARD, B. H. THOMAS, N. F. WATERS, J. W. GOWEN, and E. W. LANDSTROM (*Iowa Sta. Rpt. 1938, pt. 1, pp. 79-84, 96, 153, 154*).—Studies of the consequences of inbreeding in Holstein-Friesian cattle and Poland China hogs; the amount of inbreeding in the Poland China breed; the milk records in cow-testing associations as to persistency and inheritance of milk and fat production; the value of the Danish Landrace in the development of improved strains of swine for American conditions; the effect of inbreeding and cross-breeding in the domestic fowl; and genes and viruses as to their structure and general organization of the inheritance are briefly noted.

[Experiments in animal genetics by the Cornell Station] ([*New York*] *Cornell Sta. Rpt. 1938, pp. 90, 91, 145-147, 149*).—Brief results are given on the progress of studies of the effect of Progynon-B in combating failure of pregnancy in 7 of 10 cows treated, by S. A. Asdell, S. E. Smith, and M. G. Fincher; inheritance of differences between lines in interior egg quality, by G. O. Hall; the transmission of disease resistance and susceptibility to high temperatures in White Leghorns, Rhode Island Reds, and crosses between them, by F. B. Hutt and J. H. Bruckner; the relation of follicular hormone in the yolk of developing eggs to blood calcium, by W. F. Lamoreux and Hutt; and studies

of the genetics of curled toes, congenital blindness, nakedness, early maturity, and talpid lethal in poultry, by Hutt and Bruckner.

[Physiological and genetic studies with cattle] (*Wisconsin Sta. Bul.* 442 (1938), pp. 55-57).—Ovulation and heat were induced in "shy breeding" cows by L. E. Casida by the administration of gonadotropic hormones from the pituitary or oestrogen. The sex ratio of 1,044 fetuses varied with their age, larger percentages of males being found by A. B. Chapman, Casida, and A. Coté in the younger fetuses.

The breeding efficiency of proved (aged) sires, J. R. DAWSON. (U. S. D. A.). (*Jour. Dairy Sci.*, 21 (1938), No. 11, pp. 725-737, fig. 1).—A detailed analysis of the breeding efficiency after 5 yr. of age of 20 proved sires used at 8 branch stations of the U. S. D. A. Bureau of Dairy Industry is reported. The percentages of services to fertile cows that resulted in conceptions were tabulated with reference to age, frequency of service, season, and effect of the distance that the bulls were moved by the stations. So much variation was exhibited by the individual sires that the averages seemed to be of little value for prediction of the effect of different methods of handling on individual sires.

The influence of skeletal alterations on the milch qualities of the Sahiwal breed, W. SAYER (*Agr and Livestock in India*, 8 (1938), No. 5, pp. 541-546, pls. 5).—Progress in breeding away from loose sheaths and skin and pendulous udders in Sahiwal bulls and cows without losing the potentialities for milk production is reported.

[Inheritance studies with sheep and goats by the Texas Station], J. M. JONES, B. L. WARWICK, W. H. DAMERON, S. P. DAVIS, H. C. McPHEE, and D. A. SPENCER. (Partly coop. U. S. D. A.). (*Texas Sta. Rpt.* 1937, pp. 41, 42-44).—Brief reports are given which indicate some dominance of the genes for freedom from skin folds in Rambouillets, although only a small number of individuals have been produced. Studies with Angora goats indicate that type of lock, i. e., flat lock or ringlet, has little effect on the quality or quantity of scoured mohair. Shrinkage of mohair was generally less than that of Rambouillet wool produced under the same conditions. Data are also given on an attempt to cross a Barbary ram with sheep and goats which indicated that this species is in a different genus from either.

[Genetic studies with poultry by the Oklahoma Station], R. G. JAAP (*Oklahoma Sta. [Bien.] Rpt.* 1937-38, pp. 160-163, 175-177).—Brief reports are given on the production of a true-breeding strain of fowls which permits separation of the sexes at hatching, the possibilities of the elimination of barebacks, the mode of inheritance of baldness in several breeds (E. S. R., 79, p. 319), and rapid feathering in Plymouth Rocks. In a study of the inheritance of body size and shape in turkeys, certain differences in shank length and measurements were noted between the sexes which may be measured by shape ratios at between 20 and 28 weeks of age.

On the validity of progeny tests of sires obtained on culled populations of daughters, S. BIRD and J. W. SINCLAIR (*Sci. Agr.*, 19 (1938), No. 1, pp. 1-6, figs. 2).—To study the effects of culling on progeny tests in poultry flocks, different percentages of the lowest producers were culled from three populations. The accuracy of calculating the entire population from the truncated portion of the distribution depends on the amount of culling and how close the population approached a normal distribution. Culling should be kept between 15 and 25 percent; and only 75 percent of the culling should be done during the laying season, with 25 percent "paper culling" after completion of the test. Culling for other conditions than production should not be done while

the test is in progress. Truncated distributions after such selection are thought to be better for progeny testing than undisturbed populations.

Crossbreeding poultry for meat production, including a feeding test of taro waste and poi, C. M. BICE and B. A. TOWER. (Coop. U. S. D. A.). (*Hawaii Sta. Bul.* 81 (1939), pp. [2]+19, figs. 4).—Comparative studies of the hybrids produced from crosses of Japanese Shamo Game ♂♂ with Barred Plymouth Rock, Rhode Island Red, and Single Comb White Leghorn ♀♀ showed that, in general, the hybrids were superior in rate and economy of gains to purebreds except for the Shamo Games. The dressed carcasses of the hybrids were superior in appearance to those of the purebreds, and the hybrid carcasses in the Shamo Game × Leghorn cross lacked dark pinfeathers. The hatchability of the hybrids was definitely higher except for the Rhode Island Reds. The only sex-linked character exhibited in the day-old chicks was in the Plymouth Rock cross and involved black feathers with white spots on the heads of the ♂♂ while the ♀♀ are entirely black. All hybrid progeny were pea-combed.

In feeding experiments, taro waste proved an economical feed for fattening broilers, whereas the gains produced with poi were more costly than the standard ration.

Dual purpose poultry: Is breeding for meat type incompatible with breeding for egg type? E. A. LLOYD (*U. S. Egg and Poultry Mag.*, 45 (1939), No. 1, pp. 28-33, 52-54, figs. 18).—Progress in the improvement of production and quality of eggs, meat grade, and resistance to fowl paralysis by selective breeding over a period of 20 yr. in White Leghorns, Barred Plymouth Rocks, and Rhode Island Reds at the University of British Columbia is reviewed.

Role of inherited natural resistance to tuberculosis, M. B. LURIE (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 1, pp. 176-181, figs. 3).—Marked differences were noted between inbred families of rabbits in the way tuberculosis developed following natural infection. The three families also differed in the duration of the period of survival to artificial infection.

Nature of inherited natural resistance to tuberculosis, M. B. LURIE (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 1, pp. 181-187, figs. 5).—Families of rabbits exhibiting varying degrees of resistance to tuberculosis differed markedly in several factors, such as permeability of the skin, inflammatory response to tubercle bacilli and tuberculin, and the growth of lesions, which seemed to be jointly related to resistance.

Bent-nose in the Norway rat: A study of interaction of genes and diet in the development of the character, W. E. HESTON. (Mich. State Col.). (*Jour. Heredity*, 29 (1938), No. 11, pp. 437-448, figs. 2).—The appearance of a bent-nose condition in rats which was related to the nutrition of the animals was found to involve an abnormal curvature of the rostrum of the nose which manifested itself between 34 and 120 days of age. As diet seemed related to the appearance of the anomaly, progeny of bent-nosed parents and two other control strains were raised on seven diets of varying calcium and phosphorus levels. The frequency of the bent-nosed individuals among the progeny of bent-nosed parents varied from less than 1 percent on a well-balanced stock ration to 64.91 percent on a low calcium ration. The results from one control stock roughly paralleled results from progeny of bent-nosed parents, but almost no bent-nosed animals were produced in the other control stock. Analysis of the results indicated that the calcium:phosphorus ratio was the deciding factor in the occurrence of the condition in strains with bent-nose genes. Supplements of vitamin D reduced the deleterious effects of the calcium-phosphorus imbalance. In general, growth rate was reduced in animals on rations which produced a high percentage of bent-nosed rats, but no causal connection was found between weights at birth

or weaning and the occurrence of the anomaly. Recessive genetic factors were shown to cause variations in the appearance of the bent-nosed progeny from the different matings on the same diets. More than one pair of genes seemed responsible for the condition.

Genetical studies on immunity in mice.—II, Correlation between antibody formation and resistance, P. A. GOREZ and H. SCHÜTZE (*Jour. Hyg. [London]*, 38 (1938), No. 6, pp. 647-662).—Continuing these studies,¹ four strains of mice were tested for the relation between resistance and the production of antibodies to *Salmonella typhi murium* and *S. enteritidis*. The greater production of both H and O agglutinins by ♀♀ than ♂♂ was correlated with resistance. Differences between lines were also noted. However, no positive correlation between agglutinins and resistance was noted after immunizing with *S. enteritidis*. Inbred strains reacted more uniformly than strains selected for resistance but not intensively inbred.

Incomplete development of the diaphragm in mice causing death from asphyxia, B. L. EVAN WANG (*Anat. Rec.*, 71 (1938), No. 4, pp. 469-475, figs. 3).—The occurrence of more or less related mice exhibiting abnormalities of the diaphragm, such as to cause air to pass and be held in the abdominal cavity, evidently interfering with breathing and causing asphyxiation is described from the Peiping Union Medical College.

Terminology of sex hormones, A. S. PARKES (*Nature [London]*, 141 (1938), No. 3557, p. 36).—The author suggests the term "gynaecogenic" as more descriptive of the oestrogenic hormones to take care of their noncyclic as well as cyclic effects. "Ambisexual" might be applied to extracts exhibiting activities pertaining to both sexes. Likewise, the use of the suffix "trophic" instead of "tropic" in such words as "gonadotropic" seems logical.

Nomenclature of gonad-stimulating hormones of placental origin, E. B. ASTWOOD and R. O. GREIF (*Science*, 89 (1939), No. 2300, p. 81).—It is proposed that the term "cyonin" be applied to the hormones of chorionic origin and protein nature which act to sustain a ♀ sex hormone balance favorable to pregnancy. Thus "human cyonin" would replace "pregnancy urine," "pregnancy prolan," "anterior-pituitary-like hormone," and similar terms.

Hormone studies with the ultra-centrifuge.—II, The concentration of anterior lobe and pituitary-like hormones with the ultra-centrifuge, A. E. SEVERINGHAUS, L. LEVIN, and J. A. CHILES, JR. (*Endocrinology*, 23 (1938), No. 3, pp. 285-291, fig. 1).—By the use of the ultracentrifuge,² marked concentration of the gonadotropic potency of mare serum and castrate urine preparations was effected. The treatment did not concentrate the thyrotropic hormone.

The nipple test: Studies in the local and systemic effects on topical application of various sex-hormones, W. JADASSOHN, E. UEHLINGER, and A. MABGOT (*Jour. Invest. Dermatol.*, 1 (1938), No. 1, pp. 31-43, fig. 1).—The application of several androgens and andrenosterone and corticosterone in aqueous solutions caused significant enlargement in the nipples of ♂ guinea pigs, but oily solutions were without effect. However, oestrogens in aqueous solutions were much more effective than the androgens. Anol, a nonsterol, also proved active in the nipple test.

The effect of testosterone propionate on the genital tract of the immature female rat, U. J. SALMON (*Endocrinology*, 23 (1938), No. 6, pp. 779-783, figs. 11).—The administration of testosterone propionate caused premature opening of the vagina, follicle growth, corpora lutea formation, oestrous

¹ *Jour. Hyg. [London]*, 36 (1936), No. 1, pp. 37-49, figs. 10.

² *Jour. Expt. Med.*, 68 (1938), No. 1, pp. 1-16, figs. 7.

reaction in the smear, and marked enlargement of the preputial glands, of immature ♀ rats. In ovariectomized ♀♀ testosterone caused less marked enlargement of the uterus and opening of the vagina than in intact ♀♀. Testosterone propionate is thought to act directly on the ♀ genital tract, and indirectly on the tract in conjunction with progesterone from the corpus luteum.

Gonadotropic action of testosterone propionate on the immature mouse ovary, W. F. STARKEY and J. H. LEATHAM (*Soc. Egypt. Biol. and Med. Proc.*, 39 (1938), No. 1, pp. 218-220, figs. 4).—Single injections of testosterone propionate into 18- to 21-day-old mice caused follicle stimulation and hypertrophy of the uterus in from 48 to 72 hr. Lutein tissue was not observed. Doses of 1 and 2 mg. gave similar responses, but response was less in animals treated with 0.5 mg.

Influence of testosterone propionate on vaginal opening in the immature albino rat, H. S. RUBINSTEIN, A. R. ABARBANEL, and D. N. NADER (*Soc. Egypt. Biol. and Med. Proc.*, 39 (1938), No. 1, pp. 20-22).—Since the administration of testosterone propionate to spayed and nonspayed 26-day-old rats caused vaginal opening at an average of from 33 to 34 days, it is concluded that this action was directly on the vaginal zone and independent of the ovary. Vaginal opening in normal controls occurred at from 40 to 48 days of age, and later, if at all, in spayed ♀♀.

Effect of estrogen injections on lactogen content of female rat pituitary, R. P. REECE. (N. J. Expt. Stas.). (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 1, pp. 77-80).—Following up earlier studies (E. S. R., 78, p. 324), which showed that oestrogen injections increased the lactogen content of the pituitary glands of ovariectomized rats, normal ♀♀ were injected with doses of from 200 to 1,000 International Units of Progynon-B per day for 15 days. The pituitaries of the treated rats were almost double the size of those from untreated rats, and the total pigeon crop-gland units of lactogen per pituitary gland were increased about 40 percent with the smaller dose of oestrogen and 28 percent with the larger dose. The pituitaries from ovariectomized rats injected with 1,000 I. U. were significantly larger than from rats with ovaries intact and similarly treated.

The influence of a normal ovary on the formation of typical irradiation tissues in the X-rayed ovary, I. G. SCHMIDT (*Anat. Rec.*, 71 (1938), No. 4, pp. 409-412).—Twelve virgin ♀ guinea pigs were irradiated so that one ovary was protected. The untreated ovaries were normal and did not hypertrophy, although the irradiated ovaries became small and atrophic, and glandular tissue did not form in them. Oestrous cycles and the vaginal opening were, in general, normal. The pituitaries of treated rats were slightly larger than the pituitaries of normal ♀♀.

The influence of urine of the pregnant cattle on the mammary gland of rabbit [trans. title], N. KAWANO and S. NAKANO (*Bull. Miyazaki Col. Agr. and Forestry*, No. 10 (1938), pp. 1-21, figs. 15; *Eng. abs.*, p. 15).—Subcutaneous injection of urine from pregnant cattle into virgin, adult female nonpregnant and gonadectomized rabbits caused the animals to lactate within from 7 to 13 days. The milk produced was colostrumlike at first and later appeared normal. The stimulated mammary glands were not developed to the same degree and contained more connective tissue than is normally present. The follicular hormone (oestrin) and the trophoblast hormone (gonadotropin), both of which are produced by the placenta, were considered responsible for the mammary gland development.

Comparison of pregnancy urine injection and coitus as stimuli for ovulation in the rabbit, B. B. RUBINSTEIN (*Soc. Egypt. Biol. and Med. Proc.*,

39 (1938), No. 1, pp. 191-194).—Determination of the oxygen consumption and carbon dioxide production of tissues isolated from rabbits showed that during the 7- to 12-hr. interval after injection with pregnancy urine the oxygen consumption by the anterior pituitary per gram was practically trebled. A similar increase was noted in the oxygen consumption of adrenal tissue from 13 to 18 hr. after the administration of the pregnancy urine. No comparable increases in the metabolic rate of these glands were noted after coitus.

Effect of choline chloride on estrous cycle of mice, J. H. MOWAT and C. C. LITTLE (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 1, pp. 211, 212).—Choline chloride in doses as high as 6 mg. per day did not affect the recurrence of oestrous cycles in mice.

Growth of follicles in the ovaries of the bat *Myotis lucifugus lucifugus*, M. J. GUTHRIE and K. R. JEFFERS. (*Univ. Mo.*). (*Anat. Rec.*, 71 (1938), No. 4, pp. 477-496, figs. 5).—The ovaries of 40 ♀ bats, collected at intervals from late October until late in April, showed there were from 53 to 305 growing follicles present in them, which were equally distributed between the ovaries. Periodic seasonal variations suggested 3 peaks of growth for follicles 24 μ to 43 μ in diameter, which were followed by peaks of growth in the larger follicles. Hibernation is preceded by a fourth peak of growth. The size of the degenerating follicles varied with the season after February 6, degenerating follicles being smaller in size than earlier in the year.

Some observations on the semen production of the male fowl, W. H. BURBOWS and H. W. TITUS. (*U. S. D. A.*). (*Poultry Sci.*, 18 (1939), No. 1, pp. 8-10).—Studies of the semen production by 22 crossbred cockerels and 10 crossbred cocks about 1.5 yr. of age showed that the average yield per collection was about 19 percent greater if collections were made on alternate days as contrasted with daily collections. Full semen production of about 1 cc. per collection was reached at about 275 days of age and maintained throughout the experiment (579 days of age) except during February. On analysis after post mortem, approximately 61 percent of the variation in semen production of the individuals was related to testis size. Size of the comb and wattles and other characters including libido were not correlated with semen production.

The effect of testis hormone on the preservation of sperm life in the vas deferens of the fowl, S. S. MUNRO (*Jour. Expt. Biol.*, 15 (1938), No. 2, pp. 186-196, fig. 1).—In a study with mature young cockerels the length of sperm life in the vas deferens under conditions of vas isolation (ligature of the vas deferens at both proximal and distal ends) without castration and accompanied by castration were compared. The mature sperms in the isolated ductus deferens retained the capacity for movement in physiological saline for an average of from 26 to 28 days in each instance, thus indicating that the testis hormone is not directly concerned with the maintenance of sperm life in the excurrent reproductive ducts of the fowl.

Functional changes in fowl sperm during their passage through the excurrent ducts of the male, S. S. MUNRO (*Jour. Expt. Zool.*, 79 (1938), No. 1, pp. 71-92).—Further investigations were conducted to determine what changes, if any, occur in the capacity for movement and in the fertilizing capacity of formed sperms of fowls during their journey through the seminiferous tubules, the epididymis, and the ductus deferens. Sperms removed from the reproductive tract of recently killed mature cockerels and examined while suspended in physiological salt solution indicated that sperm motility is very slight in the testis, definitely increases in the epididymis, but reaches a maximum when in the vas deferens. When hens were artificially inseminated with sperms obtained from the various regions of the tract, fertility resulted in a very small

percentage of cases, with sperms from the testis, somewhat more frequently with those from the epididymis, and in a high percentage of cases with those from the vas deferens. The sperms traveled very quickly through the reproductive tract, passage occurring in 24 hr. in sexually active males but requiring from 72 to 96 hr. in nonactive males. It was evident that a male environment was necessary for the maturation or attainment of functional maturity of the fowl sperm.

On the exchange of bull semen between England and Holland, J. EDWARDS, A. WALTON, and J. SIEBENGA (*Jour. Agr. Sci. [England]*, 28 (1938), No. 3, pp. 503-508).—Semen samples collected from an excellent-breeding bull in England were employed for the insemination of 26 difficult-breeding cows in the Netherlands. The semen samples were from 28 to 57 hr. old. Only 8 cows conceived. No pregnancies followed the use of nonmotile semen. One of 3 cows inseminated in England with semen 28 hr. after collection in the Netherlands calved normally. No conceptions resulted from five inseminations with 72- and 48-hr. semen samples in poor condition. The service record of the Dutch bull was below normal.

Artificial insemination in dairy cattle, C. L. COLE and L. M. WINTERS. (Minn. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 2, pp. 107-110).—Methods of semen collection and artificial insemination of 121 cows in the vicinity of the North Central Substation at Grand Rapids, Minn., are described. Considering all of the cows, 1.77 inseminations were required per conception.

FIELD CROPS

[Agronomic research in Alabama, 1937], J. T. WILLIAMSON, J. W. RICHARDSON, R. W. TAYLOR, H. B. TISDALE, J. B. DICK, E. L. MAYTON, D. G. STURKIE, E. V. SMITH, and J. F. DUGGAR (*Alabama Sta. Rpt. 1937*, pp. 9-12, 25, 26, 30, 31).—Progress results are reported from experiments (E. S. R., 78, p. 774) concerned with effects on stands of 6-8-4 fertilizer at different rates, ammonium sulfate v. sodium nitrate on limed and unlimed soil, varieties and fertilizers in relation to wilt disease, merits of varieties, and effects of environmental factors on oil content of seed, all with cotton; manure, sodium nitrate, and vetch as nitrogen carriers for cotton and corn in rotation; effect of time of planting on stands of Dallis grass; germination studies in dry soil, and hot water treatment v. scarification, both with seed of *Orotalaria spectabilis*; frequency of cutting *Lespedeza sericea*; seasonal activity of bulbs of wild garlic as related to its control by creosote-kerosene or other sprays; and the life history of nutgrass as related to possible control methods.

[Farm crops research in Iowa], C. P. WILSIE, H. D. HUGHES, L. C. BURNETT, J. B. WENTZ, C. Y. CANNON, M. G. WEISS, E. V. COLLINS, J. N. MARTIN, W. H. PIERRE, P. M. NELSON, B. LOWE, J. L. ROBINSON, L. W. FORMAN, A. G. NORMAN, I. E. MELIUS, C. S. REDDY, W. F. BUCHHOLTZ, C. M. NAGEL, A. L. BAKKE, R. H. PORTER, J. M. AIKMAN, M. DONNELLY, A. T. ERWIN, N. D. MORGAN, J. B. DAVIDSON, C. K. SHEDD, A. A. BRYAN, R. M. HIXON, W. G. GAESSLER, E. L. ERICKSON, R. C. ECKHARDT, R. W. JUGENHEIMER, J. C. ELDREDGE, and E. W. LINDSTROM. (Partly coop. U. S. D. A.). (*Iowa Sta. Rpt. 1938*, pts. 1, pp. 53-63, 65-69, 115, 116, 118, 120, 121, 178, 179-181, 182, 184-186, figs. 4; 2, pp. 20, 21, 23-28, 29-33, 33-41, 41-45, figs. 3).—In part 1, further reports of progress (E. S. R., 79, p. 470) are made on breeding work with oats, barley, wheat, soybeans, sweet-clover, bromegrass, timothy, potatoes, and sweetpotatoes; variety tests with oats, wheat (coop. Minn. Expt. Sta.), barley, red clover, sweetclover, soybeans, edible soybeans, potatoes, and sweetpotatoes; adaptation studies with Mukden and Kanro soybeans and Korean lespedeza; seed treatments with seed flax varieties;

cultural studies with reed canary grass and with alfalfa varieties and alfalfa-timothy mixtures on bacterial wilt-infected soil; trials of legumes for green manure for corn and oats; relative value of red clover, alfalfa, and sweetclover as soil-building crops; studies of the adaptability of grasses and legumes to establishment and growth on subsoil v. fertile top soil; fertilizer and varietal factors affecting storage quality of sweetpotatoes; studies of sugar production and storage in sugar beets; fertilizer and propagation tests with sweetpotatoes; permanent pasture improvement; effects of fertilizers and grazing methods on soil conditions and plant growth on permanent pastures; properties and herbicidal action of sodium chlorate mixtures; and studies of the permeability of weed seed, particularly bindweed, to water.

Corn research proceeding as projects under the Iowa Corn Research Institute, covered in part 2, dealt with genetic relations of inbred lines, including influence of intensity of inbreeding on development of inbred lines, second cycle inbred lines, growth curves of inbred and hybrid corn, and maternal influence on tillering in corn; developing inbred lines of corn resistant to stalk and ear rots; genetic studies; improving inbred lines by crossing followed by selfing and sibbing; improvement through the use of inbred lines; growth response of hybrids and varieties on soils of different levels of fertility and on various soil types; tests of varieties, strains, and hybrid combinations in different parts of Iowa; hill spacing of check planted corn; comparison of single-plant hill spacings; corn production methods and equipment; correlation between composition and strength of stalk; maintenance of pure seed sources of improved varieties through field inspection and certification; production and distribution of seed of corn hybrids and of their parents; and breeding and varietal studies with popcorn. Other activities related to corn production were concerned with seed increase of new or improved varieties of field crops; technics used in seed analysis; and physiology of field bindweed (*Convolvulus arvensis*).

[Field crops work in Maine], R. M. BAILEY, D. S. FINK, F. CHADWICK, JR., J. A. CHUCKA, A. HAWKINS, and B. E. BROWN. (Partly coop. U. S. D. A.). (*Maine Sta. Bul.* 391 (1938) pp. 261, 267-277, 284-286, 287).—Fertilizer tests with potatoes involving rates of application with the usual and several spacings, different formulas, variations in potassium and magnesium contents, acid v. neutral fertilizers, limed v. unlimed soil, sources of phosphorus and potassium, and uncommon elements; variety tests with corn, alfalfa, and potatoes; and pasture improvement by fertilization and other practices are again (*E. S. R.*, 79, p. 41) reported on.

[Field crops and plant improvement research in New York], J. A. BIZZELL, E. W. LELAND, J. K. WILSON, L. F. and F. RANDOLPH, S. RAVAGE, J. EINSSET, D. B. HAND, R. A. EMERSON, A. C. FRASER, H. H. LOVE, E. DORSEY, F. P. BUSSELL, W. T. CRAIG, R. G. WIGGANS, J. R. LIVERMORE, A. G. NEWHALL, W. C. MUENSCHER, and O. SMITH. (Partly coop. U. S. D. A.). ([*New York Cornell Sta. Rpt.* 1938, pp. 82, 83, 101, 102, 125, 126, 127, 128, 131, 160, 162).—Progress results are reported briefly from breeding work and genetic studies with corn, wheat, rye, oats, and barley; breeding experiments with soybeans and potatoes; studies on the number, form, and behavior of the chromosomes in corn and other plants, with special reference to their role in heredity, and on tetraploid corn, and the production of tetraploid strains of teosinte, Sudan grass, barley, iris, and other plants; experiments on the protein content of timothy and of alfalfa cut at several progressive stages of growth, nitrogen fertilization for timothy, and the production of silage from crops high in protein; handling and storage of seed potatoes; factors affecting chemical composition and culinary quality of potatoes; and control of weeds in onions by the use of herbicides.

[Agronomic work in North Dakota] (*North Dakota Sta. Bmo. Bul.*, 1 (1939), No. 3, pp. 4, 5, 9-12, 17-19, 25-28, 31-39, figs. 3).—Recent progress in experiments with field crops and in related activities is reviewed in brief articles entitled *The Identification Service for Weeds and Other Plants*, by O. A. Stevens (pp. 4, 5); *Perennial Peppergrass in North Dakota*, by E. A. Helgeson (pp. 9-12); *Seed Flax Production and Flax Research*, by T. H. Hopper (pp. 17-19); *Does Wheat "Run Out"?* by L. R. Waldron (pp. 25-28); *Which Rust Resistant Wheats Are Most Desirable?* by T. E. Stoa and R. H. Harris (pp. 31-35); *New Varieties of Rust Resistant Wheat*, by L. R. Waldron and R. H. Harris (pp. 35-37); and *Breeding Potatoes for North Dakota*, by H. Mattson (pp. 37-39).

[Field crops research in Oklahoma, 1936-38], J. E. WEBSTER, H. B. CORDNER, F. A. ROMSHE, H. J. HARPER, H. F. MURPHY, H. DUNLAVY, L. L. LIGON, H. W. STATEN, C. B. CROSS, W. B. GEBNERT, and J. C. IRELAND. (Partly coop. U. S. D. A.). (*Oklahoma Sta. [Blen.] Rpt.* 1937-38, pp. 5, 103-105, 112-115, 184-188, 189-215, figs. 10).—Field crops work (E. S. R., 77, p. 38), reported on briefly for the above period, included variety tests with cotton, corn (hybrids), wheat, seed flax, potatoes, sweetpotatoes, and miscellaneous grasses and legumes; breeding work with cotton, corn, and grain sorghum; influence of wide v. narrow small grain rows on stands of lespedeza and sweetclover; investigation of floral structures and seed production in alfalfa; cultural (including planting) experiments with cotton, oats, and grasses; fruiting studies with cotton varieties; crimson clover for forage and soil improvement; merits of limestone in a wheat-sweetclover rotation; effects of time of applying nitrogen fertilizer on protein content of wheat; effect of seed treatments and soil conditions, especially temperature, on yields of fall-crop potatoes; storage experiments with spring-grown potatoes; curing studies with sweetpotatoes; feeding castor bean leaves to grasshoppers; and chemical studies on weed root reserves in relation to control.

[Special agronomic investigations in Oregon]. (Coop. U. S. D. A. et al.). (*Oregon Sta. Circ.* 130 (1938), pp. 12-14, 16, 17, 36-38, 40, 41, figs. 24).—Progress results, reported from agronomic experiments authorized by the 1937 legislature, included the establishment of good sod-forming grasses on logged-off land where a reasonably good burn of slashings had been made; new crops indicated for Malheur County, including Virginia and Illini soybeans for green manure or forage and Cayuga and Minsoy for seed, Newland and Rio flax, Minnesota 1085-4 wheat, hybrid seed corn, Trebi barley, White Rose potatoes, strawberry clover, and Orestan alfalfa; fertilizer tests in Malheur County showing favorable yield responses of potatoes, sugar beets, alfalfa, and other crops to treble superphosphate, of potatoes but not alfalfa to sulfur, and of several crops to complete fertilizer; weed control investigations, including chemicals, e. g., a sodium chlorate-oil emulsion making 100 percent kill of Canada thistle, control of annual weeds in grain by a 1.5-percent solution of Sinox and a 5-percent solution of sulfuric acid, control of lawn weeds by Sinox, copper nitrate, and kerosene and other chemicals, control of poison-oak by 1:60 solution of sodium arsenite or borax, and control of Canada thistle and morning-glory by cultivation; and certification and regulatory activities of the seed testing service.

[Field crops research in Pennsylvania], D. E. HALEY, O. OLSON, C. F. NOLL, C. J. IRVIN, H. B. MUSSEY, J. W. WHITE, J. S. COBB, J. J. REID, E. L. NIXON, D. W. MCKINSTY, and W. THOMAS. (Partly coop. U. S. D. A.). (*Pennsylvania Sta. Bul.* 367 (1938), pp. 7, 8, 16, 17, 18, 19-21, 22, 23, 24, 32, 33, 39, 44, 48, fig. 1).—Agronomic studies, reported on briefly, included breeding work with potatoes, wheat, oats, soybeans, grasses, and red clover; inheritance studies with red clover; variety trials with wheat, corn (and hybrids), oats, barley, potatoes, soybeans, and alfalfa; effects of soil reaction and planting date on yield and

cooking quality of potatoes; foliar diagnosis of the nutrition of corn and potatoes (E. S. R., 80, p. 188); research on microflora associated with fermentation of cigar-leaf tobacco during curing; fertilizer experiments with tobacco, hay, and turf grasses; response in hay yields to nitrogen carriers on limed and unlimed soil; and studies of soil acidity tolerance of strains of red clover and *Rhizobium trifolii*.

[Agronomic research in South Carolina], G. B. KILLINGER, H. P. COOPER, R. W. WALLACE, J. B. EDMOND, H. J. SEFICK, C. H. ARNDT, G. M. ARMSTRONG, C. C. BENNETT, B. S. HAWKINS, C. S. PATRICK, E. D. KYZER, J. E. LOVE, W. H. JENKINS, E. L. HALL, J. R. MATTISON, W. W. KIRVEN, F. M. HARRELL, J. D. McCOWN, W. M. LUNN, H. A. McGEE, J. A. RILEY, N. MCKAIG, JR., W. A. CARNS, A. B. BOWEN, E. M. ROLLER, L. E. SCOTT, E. W. FAIRES, W. C. BARNES, R. L. SMITH, J. M. JENKINS, JR., and W. B. ROGERS. (Partly coop. U. S. D. A. et al.). (*South Carolina Sta. Rpt. 1938*, pp. 33-41, 46-52, 61-63, 85, 87-89, 94, 99-103, 105-114, 125-129, 132-136, 144-150, 151-156, 159, 160, 162-167, 167-172, 177, 179, 181, 182, 184-186, figs. 3).—Progress reports are made again (E. S. R., 79, p. 322) from field crops experiments at the station and substations, including variety tests with cotton, corn, oats, wheat, grain sorghum, sorgo, sugarcane, cowpeas, soybeans, sweetpotatoes, potatoes, and crotalaria species; tests of kudzu and of different green manure crops for truck soils; breeding work and genetic studies with cotton; hybridization experiments with sea-island and upland cotton; fertilizer experiments with potatoes, sweetpotatoes, and soybeans; response of potatoes to limestone and basic slag; fertilizer and nutrition studies with cotton dealing with placement, time and rate of applying potassium and other fertilizers, potassium carriers with and without lime and magnesium sulfate, acid-forming v. non-acid-forming fertilizers, and rates of stable manure in the drill; the comparative value of a cover crop of rye and hairy vetch, fresh manure, and their combination in production of cotton; cottonseed storage experiments; studies of variation in fiber length in several lines of Super-Seven cotton; tobacco experiments, including effects of various rotations, rates and forms of potassium fertilizers, and fertilizer formulas recommended for bright flue-cured tobacco and plant beds: sweetpotato experiments concerned with yields from vine cuttings v. sprouts of the same parentage, nutrient deficiency symptoms, and effect of time of planting and spacing on yields of the Porto Rico variety; comparison of Biloxi soybeans, Ootootan soybeans, and cowpeas for hay; Biloxi soybeans with four varieties of sorgo for silage; and establishing and maintaining lespedeza and white clover in carpet grass pasture.

[Agronomic investigations in Texas], W. H. FRIEND, E. B. REYNOLDS, H. E. REA, D. T. KILLOUGH, T. R. RICHMOND, R. E. HARPER, G. T. McNESS, R. H. WYCHE, H. M. BEACHELL, R. E. DICKSON, B. C. LANGLEY, C. E. FISHER, P. C. MANGELSDORF, R. G. REEVES, H. P. SMITH, D. L. JONES, P. R. JOHNSON, R. H. STANSIL, P. B. DUNKLE, V. L. COXY, W. H. DAMERON, R. E. KAPER, J. R. QUINBY, G. S. FRAPS, R. L. HENSEL, J. H. JONES, E. S. McFADDEN, P. A. YOUNG, J. J. TAUBENHAUS, R. A. HALL, C. H. McDOWELL, I. M. ATKINS, F. GAINES, J. J. BAYLES, H. F. MORRIS, E. K. CROUCH, J. C. STEPHENS, G. H. GODFREY, L. E. BROOKS, and E. MORTENSEN. (Partly coop. U. S. D. A. et al.). (*Texas Sta. Rpt. 1937*, pp. 36, 67-84, 86-93, 94, 95, 107, 115, 166-169, 170-173, 179-181, 182-186, 187-191, 198-206, 207-209, 210-219, 220-222, 230-232, 232-234, 236, 238-242, 249-256, 257, 258, 260-262, 265, 266, 277, 279, 280, 284-290, 302, 303).—Results are again reported briefly from agronomic and plant breeding experiments (E. S. R., 79, p. 42) at the station and substations, including varietal tests with cotton, corn (and corn hybrids), wheat, oats, barley, rice, grain sorghum, sorgo, sugarcane for sirup, flax, peanuts, soybeans, cowpeas, velvetbeans, alfalfa, lespedeza, clover,

bur clover, sweetclover, vetch, winter peas, sesame, crotalaria, potatoes (seed stock), and miscellaneous winter and summer legumes and grasses; growing of spineless cactus (*Opuntia ellisiana*); breeding work with cotton, wheat, oats, barley, corn, rice, grain sorghum, Sudan grass, sorgo, broomcorn, sorghum for popping, cowpeas, buffalo grass, and peanuts; development of cotton varieties adapted to mechanical harvesting; inheritance studies with cotton, corn, broomcorn, and different sorghums; studies of the genetic and cytological relationships of corn, *Euchlaena*, and *Tripsacum*; hybrid vigor in sorghum; cultural (including planting) tests with cotton, corn, oats, rice, grain sorghum, Sudan grass, buffalo grass, flax, soybeans, sweetclover, sesame, and potatoes; effects of interplanting corn and grain sorghum and sweetclover with Sudan grass and with oats; treatment of cottonseed; dusting sulfur on peanut vines; seedbed preparation studies; comparisons of corn and sorghums; effects of grain sorghum and corn on succeeding small grain crops; irrigation tests with grain sorghum and cotton; studies of artificial plats for field experiments in soil improvement; numerous crop rotation and sequence experiments; fertilizer trials with crops in rotation, corn, wheat, oats, rice, potatoes, grain sorghum, pasture, sugarcane, and cotton; methods of applying fertilizers for cotton and rice; effects of fertilizers on germination of rice seed; tolerance of rice to different soil reactions adjusted with lime and sulfur; polyhalite as a source of potassium for fertilizers; nitrogen sources for cotton and corn; cotton burs v. manure as cotton fertilizers; continuous cotton v. cotton grown from two-thirds to one-fourth of the period in rotation; green manures for cotton, corn, potatoes, and other crops; inoculation studies with soybeans and other legumes; rice weed control with sulfuric acid solutions; soil fertility and improvement studies; hairy vetch for soil improvement; germination and longevity of the seed and control of bitterweed; control of Johnson grass and nutgrass with chloropicrin; control of pricklypear and pasture weeds; production and germination of buffalo grass seed and establishment of buffalo grass pasture; and other pasture improvement and management investigations concerned with plants and seeds mixtures for different types of pasture, effects of fertilizer treatments on yield and chemical and botanical composition of herbage, introduction of new grasses and legumes and sods for observation, grazing tests with new grasses, inoculation tests with pasture legumes, combination woodland and pasture studies, different rates of phosphate on strains of Subterranean clover, effects of fertilizers and oak ashes and of mineral fertilization on establishment and survival of clovers, both on native pasture, and influence of deferred grazing on increase of desirable winter-growing range plants.

Irrigation of small grain at germination may reduce yield as much as 10 percent. D. W. ROBERTSON (*Colo. Farm Bul. [Colorado Sta.], 1 (1939), No. 1, pp. 5-7*).—Experiments with wheat, largely noted earlier (E. S. R., 78, p. 348), showed that too early an irrigation of small grain may reduce yields about 10 percent because the irrigation water carries the available nitrogen below the feeding area of the roots.

Alfalfa in Colorado. D. W. ROBERTSON, R. M. WEIHING, and O. H. COLEMAN (*Colorado Sta. Bul. 450 (1938), pp. 26, figs. 7*).—Cultural, irrigation, and harvesting practices and varieties, based on results of experiments and experience over an extended period, are suggested for growing the crop in Colorado. Titles of 40 station contributions on alfalfa, 1888-1937, are appended.

Recommendations include a level, smooth, well-prepared seedbed; spring planting or early fall planting in July or August; from 8 to 10 lb. of good clean seed drilled from 0.5 to 1 in. deep or broadcasted and the land harrowed or packed, and either sown alone or with a companion crop of field peas or flax;

and irrigation depending on water supply and soil type. The hay should be cut in from one-tenth to one-fourth bloom and raked into windrows when wilted, allowed to cure partially in the windrow, and while still a little damp, either bunched or cocked and allowed to cure, and stacked in high well-peaked stacks. Varietal recommendations include Meeker Baltic for short rotations, with Grimm and Hardistan second, and Hardistan for long rotations where a stand (E. S. R., 79, p. 619) of alfalfa is to be kept longer than 3 yr.

Ladino clover for western Oregon, H. A. SCHOTH. (Coop. U. S. D. A.). (*Oregon Sta. Circ.* 129 (1938), pp. 8, figs. 2).—Practical suggestions for growing Ladino clover (*Trifolium repens latum*) based on the cooperative experiments and observations consider environmental needs, seedbed preparation, seeding mixtures and practices, fertilizer and irrigation requirements, and methods of managing pasture and handling the crop for hay and seed.

Illinois corn performance tests, 1938, G. H. DUNGAN, A. L. LANG, J. H. BIGGER, B. KOEHLER, and O. BOLIN. (Coop. U. S. D. A. et al.). (*Illinois Sta. Bul.* 450 (1939), pp. 225-272, figs. 5).—The 246 kinds of corn (E. S. R., 78, p. 776) compared on 10 fields in 1938 included 219 hybrids and 27 open-pollinated varieties. The number of entries in each field was limited to 60, which included 5 adapted open-pollinated varieties selected to serve as a check.

The 5 best hybrids on all 10 fields surpassed the best 5 open-pollinated varieties by an average of 15.5 bu. per acre and by 13.2 in percentage of erect plants. The 5 hybrids excelled in 9 fields in yield of sound corn and on all fields in percentages of erect plants. In the 2 northern and 1 central sections even the 5 poorest hybrids on the average outyielded the 5 open-pollinated corns. Two- and 3-yr. summaries of results in several northern and central sections show that certain hybrids were definitely superior to adapted open-pollinated varieties, but the advantage was small or nil in the more southern sections.

Dropped ears were appreciable only in 2 fields, at Reddick 0.92 percent and Littleton 0.55 percent; 15 hybrids in the Reddick field and 10 hybrids in the Littleton field dropped 1 percent or more of their ears. Many hybrids were above average in resistance to two species of corn rootworms, the only insects causing noteworthy damage on the 1938 fields. A combination of Stewart's disease and *Diplodia* stalk rot reduced yields as much as 50 percent in some localities in 1938, most severely in south-central Illinois. With exceptions, the high-yielding hybrids appeared to be more susceptible to the above disease complex than lower-yielding hybrids. Disease susceptibility seemed to be correlated most highly with earliness of maturity.

Soil adaptation tests in 1938 continued to demonstrate the need for fertile soil to take full advantage of the high productiveness of good hybrids. However, yield alone is not always a complete index to the adaptability of a variety or hybrid to a given soil, for lodging, type of ear, and kernel formation may also be influenced greatly by productivity level.

The 1938 Iowa corn yield test, M. S. ZUBER and J. L. ROBINSON. (Coop. U. S. D. A. et al.). (*Iowa Sta. Bul.* 379 (1939), pp. 77, fig. 1).—The 1,110 entries made in the 12 fields of the 1938 Iowa corn yield test were grown cooperatively in the same groupings and in a similar growing season as in 1937 (E. S. R., 79, p. 45). Hybrid corn averaged in yield 16.9 percent more than open-pollinated varieties, and the greatest relative increase was in the 2 districts suffering most from drought. An experimental hybrid yielded highest in 8 districts, a regular hybrid in 3, and the highest yielding regular and experimental hybrids were equal in 1 district. The lowest yielding entry in 7 districts was an experimental hybrid, in 4 districts an open-pollinated corn, and in 1 district a regular hybrid. An excessive number of the better performing

combinations in the northern and north-central sections had moisture contents above the average open-pollinated strains. Data on variations among hybrids again emphasized the fact that many of the commercial hybrids on the market can be regarded as mediocre to poor.

Section entries with highest performance scores in the regular open-pollinated, regular hybrid, and experimental hybrid classes, respectively, were for the northern section Kossuth Reliance, Pioneer Hi-Bred 349, and Funk Hybrid G-114; for the north-central section Iowill, Funk Hybrid G-53, and Feldcorn 853; for the south-central section Coppock Utility, Pioneer Hi-Bred 313, and Iowa Hybrid 3110; and for the southern section Krug, Dekalb 827, and Iowa Hybrid 3395. Because of its performance in the northern section, the grower of Pioneer Hi-Bred 349 was awarded a trophy for the regular section entry having the highest performance score.

Corn hybrids for Missouri, G. F. SPRAGUE. (Coop. U. S. D. A.). (*Missouri Sta. Circ. 201 (1939), pp. 27, figs. 23*).—Methods of producing and testing hybrid corn are outlined, and its value and limitations are pointed out. Hybrids recommended for Missouri from results of performance tests include Missouri No. 8 and No. 47 for culture throughout the State, with No. 47 usually excelling in northern Missouri, and Iowa 13 for extreme northern Missouri.

Progress report on fertility investigations with peanuts in 1938, E. R. COLLINS and H. D. MORRIS (*North Carolina Sta. Agron. Inform. Circ. 117 (1939), pp. [7], figs. 5*).—In the first year of studies on four soil types in five fields in the peanut belt in eastern North Carolina, peanuts responded in yield increases to gypsum only on two Dunbar-Lenoir fine sandy loams with respective pH values of 5.9-6.1 and 4.6-4.8, to lime only on the latter soil, to potassium alone only on Norfolk very fine sandy loam, to phosphorus on no soils with increased yield but with a decrease on Ruston loamy sand, and to potassium alone and to 300 lb. per acre of a 2-8-4 fertilizer only on the Norfolk soil.

Reseeding with grasses native to Colorado increases forage crops on depleted ranges, E. W. NELSON and C. H. WASSER (*Colo. Farm Bul. [Colorado Sta.], 1 (1939), No. 1, pp. 9-13*).—Reseeding practices suggested as productive on depleted ranges in different parts of the State include good soil, drilling seed of adapted grasses from 0.75 to 1.5 in. deep—preferably 1 in. deep and early on well-prepared seedbeds, seeding in high stubble where soil blowing occurs or after vegetation is removed in nonblowing areas, mowing weeds on newly seeded areas, where practicable, at least twice a year, and permitting no grazing in the first year after seeding. Improvement by better grazing systems should be tried before artificial reseeding is attempted.

How to keep and increase black grama on southwestern ranges, R. S. CAMPBELL and E. C. CRAFTS. (Coop. Univ. Ariz.). (*U. S. Dept. Agr. Leaflet 180 (1939), pp. 8, figs. 5*).—Management and utilization practices are outlined and the means of spreading are described for black grama grass (*E. S. R.*, 71, p. 465), considered essential to southwestern ranges because of its wide occurrence, forage value, and use in soil conservation.

HORTICULTURE

[Horticultural studies by the Alabama Station], L. M. WARE, H. HARRIS, and E. W. MOELWEE (*Alabama Sta. Rpt. 1937, pp. 26-29*).—Reports are presented on the following studies: The effect of various sources of nitrogen upon the yield of vegetable crops, varieties of muscadine grapes, and the influence of photoperiod modification on the flowering of the chrysanthemum and aster.

[Horticultural studies by the Iowa Station], B. B. SPROAT, A. F. DODGE, E. W. LINDSTROM, E. C. VOLZ, T. J. MANEY, B. S. PICKETT, H. H. FLAGGE, H. L. LANTZ, A. T. ERWIN, E. S. HABER, and N. D. MORGAN (*Iowa Sta. Rpt. 1938, pts. 1, pp. 147, 148, 149, 150, 164-178, 179, 181, 182, 183, 184, 186, 187, figs. 2; 2, pp. 33, 41*).—In part 1, the following studies are discussed: Conservation nursery cultural practices; inheritance of fruit size and shape in tomatoes; varieties of iris; growing of uniform stocks for propagating the apple; development of new stocks, particularly dwarfing stocks, for apples; soil management of apple orchards; response of apple varieties to storage temperatures; breeding apples, pears, and plums; species crosses to develop hardy peaches; new apple varieties; breeding of anthracnose-resistant black raspberries; storage of the Jonathan apple with respect to control of functional disorders; varieties and soil management of strawberries in southeastern Iowa; stock-on-scion influences in the apple; vegetative propagation of woody plants as related to juvenile and mature tissues; breeding and testing of rose stocks; growth-promoting substances as aids to propagation by cuttings; culture of asparagus; commercial fertilizer v. manure for muskmelons; substitute crops for cabbage and melon "sick" soils in southeastern Iowa; varieties of vegetables and muskmelons; and ecological factors affecting the growth of asparagus.

Part 2 takes up sweet corn breeding and the nature of drought resistance in inbred and hybrid lines of sweet corn.

[Horticultural studies by the Maine Station], M. T. HILBORN, R. M. and D. M. BAILEY, J. A. CHUCKA, S. M. RALEIGH, I. M. BURGESS, D. FOLSOM, F. B. CHANDLER, and I. C. MASON (*Maine Sta. Bul. 391 (1938), pp. 243-256, 306-311, figs. 2*).—Among studies the progress of which is discussed are the nature, causes, and prevention of winter injury to apple trees; sweet corn breeding, spacing, and fertilization; breeding and planting rates of beans; vegetable variety trials; development of scab-resistant cucumbers; boron deficiency in rutabagas, cauliflower, and related plants; breeding and variety trials with small fruits; and blueberry fertilization, culture, weed control, and propagation.

[Horticultural studies by the Pennsylvania Station], J. W. SINDEN, C. E. MYERS, M. T. LEWIS, W. B. MACK, W. THOMAS, R. D. ANTHONY, F. N. FAGAN, C. O. DUNBAR, N. F. FARRIS, H. K. FLEMING, H. W. THURSTON, E. I. WILDE, R. P. MEAHL, G. J. STOUT, E. M. RAHN, and F. W. HALLER (*Pennsylvania Sta. Bul. 367 (1938), pp. 34, 35, 47-50, 51, 52, 53, 54, fig. 1*).—Included are brief reports on studies in mushroom culture: inbreeding of sweet corn; tomato, rhubarb, and lettuce breeding; fertilization of truck crops; foliar diagnosis of crop nutrition; soil management in peach orchards; apple storage and use of growth-promoting substances in apple propagation; breeding of snapdragons; testing of ornamentals; and the asexual production of ornamentals with growth-promoting substances; variety and strain tests of celery, beets, carrots, cabbage, peas, beans, peppers, and tomatoes.

[Horticultural studies by the Oklahoma Station], V. G. HELLER, F. B. CROSS, H. B. CORDENER, F. A. ROMSHE, G. F. GRAY, R. L. SCOTT, and E. L. HARTMAN (*Oklahoma Sta. [Blen.] Rpt. 1937-38, pp. 3, 4, 98-100, 101-103, 105-111, 115-134, figs. 9*).—Included are brief reports on the following studies: Effect of saline waters on greenhouse plants; effect of growth-promoting substances on root formation in cuttings and young pecan trees; management of pecan groves; varieties of pecans; grafting waxes for covering propagation wounds; varieties, irrigation, and fertilizers for vegetables; use of cloth houses for tomato growing; irrigation and fertilizer for strawberries; varieties of small fruits; comparative transpiration rates of different strawberry varieties; varieties of tree fruits and grapes; causes of uneven ripening of grapes; soil media for greenhouse flowers; and varieties of tomatoes for greenhouse culture.

[Horticultural studies by the Oregon Station] (*Oregon Sta. Circ.* 130 (1938), pp. 2, 3, 19, 20, figs. 8).—Included are progress reports on the following investigations: The handling and storage of rose plants, ethylene as a cause of premature defoliation of holly, use of growth hormones in propagation, the preservation of peony blooms, and the culture and handling of hops.

[Horticultural studies by the South Carolina Station], A. M. MUSSEY, L. E. SCOTT, J. M. JENKINS, JR., and W. C. BARNES (*South Carolina Sta. Rpt.* 1938, pp. 52–54, 74, 75, 157–159, 160–162, 172–176, 178, 179–181, 182–184, 188, 189, figs. 5).—Brief reports are presented on the progress of studies relating to fruit varieties, particularly peaches, grapes, and berries; fertilizers and cover crops for peaches; grape rootstocks; breeding of spineless okra and of cabbage; varieties and fertilization of vegetables, with particular reference to asparagus, beans, peas, tomatoes, cucumbers, watermelons, and cantaloups.

[Horticultural studies by the Texas Station], S. H. YARNELL, J. F. ROSEBOROUGH, H. F. MORRIS, J. C. RATSEK, W. H. FRIEND, E. MORTENSEN, J. F. WOOD, G. H. GODFREY, H. M. REED, R. H. STANSEL, W. S. FLORY, L. E. BROOKS, L. R. HAWTHORN, R. A. HALL, R. H. WYCHE, D. L. JONES, J. J. BAYLES, and W. H. DAMEBON. (Partly coop. U. S. D. A.). (*Texas Sta. Rpt.* 1937, pp. 29–36, 36–39, 169, 173–175, 186, 187, 191, 192, 232, 237, 242, 243, 244, 245, 260, 273–277, 277–279, 280, 281, 290–293, 294–301, 302).—Included are brief reports on studies relating to fruit, ornamental, and vegetable adaptation; culture of the blackberry and rose; rootstocks for citrus; citrus breeding, fertilizing, culture, and storage; date varieties and propagation; chromosome structure of the Meyer lemon; breeding and processing of the fig; grape rootstocks and pollination; peach, plum, blackberry, dewberry, and strawberry breeding; orchard heating; development of vegetables for canning and freezing; vegetable culture and fertilization; types of vegetables; cabbage breeding; crucifer hybridization; vernalization of cabbage seed; storage of cucumbers; factors influencing the quality and yield of onions and spinach; tomato breeding and pruning; the cause and nature of puffing in the tomato; breeding of ornamentals, including the oleander, oak, and rose; use of growth-promoting substances for cuttings of oak, plum, peach, etc.; the chromosome structure of oak and *Habranthus robustus*; and fertilizer and adaptation studies with tung oil and slash pine trees.

The water-culture method for growing plants without soil, D. R. HOAGLAND and D. I. ARNON (*California Sta. Circ.* 347 (1938), pp. 39, pls. 4, figs. 7).—This is a presentation of information as to the historical background and development of the growing of plants in water solutions containing essential mineral nutrients for growth. In discussing the economic possibilities of water culture, the authors state that "indispensable to profitable crop production by the water-culture method is a general knowledge of plant varieties, habits of growth, and climatic adaptations of the plant to be produced, pollination, and control of disease and insects; in other words, the same experience now needed for successful crop production in soils." Formulas for the preparation of nutrient solutions are suggested.

Plant injection for the diagnosis of mineral deficiencies, B. F. G. LEVY (*Sci. Hort.* [Wye, Kent, Eng.], 7 (1939), pp. 50–59, figs. 9).—This is a discussion of technic.

[Vegetable studies by the Cornell Station], C. H. MYERS, R. A. EMERSON, H. C. THOMPSON, A. G. NEWHALL, P. H. WESSELS, R. H. WHITE-STEVENS, H. S. CUNNINGHAM, J. E. KNOTT, G. J. RALEIGH, R. L. CAROLUS, C. H. DEARBORN, O. A. LORENZ, H. PLATENIUS, P. WORK, and C. L. VINCENT ([*New York*] *Cornell Sta. Rpt.* 1938, pp. 127, 156–160, 161, 162).—Included are reports on the following studies: Breeding cabbage for yield and uniformity; breeding celery of self-blanching types for quality, disease resistance, and yield; asparagus spacing;

fertilizer requirements of vegetables; green-manure and cover crops; soil reaction for vegetable crops; crop adaptation and soil management for vegetables grown on muck soils; lettuce improvement; soil deficiencies for vegetables and the use of borax; storage and precooling of vegetables on the farm; and vegetable handling and storage.

The vegetable growing business, R. L. and G. S. WATTS (*New York: Orange Judd Pub. Co., 1939, pp. XVII+549, figs. 148*).—This is a comprehensive treatise devoted to the principles and practices of growing and marketing vegetables.

Problems in the production of Iceberg lettuce in New York, J. E. KNOTT, E. M. ANDERSEN, and R. D. SWEET (*[New York] Cornell Sta. Bul. 714 (1939), pp. 17, figs. 6*).—Of varieties and strains of Iceberg lettuce tested at several locations, a hybrid known as Imperial 44 and developed by the U. S. Department of Agriculture showed unusual capacity for producing firm, marketable heads even under conditions that greatly reduced heading in other varieties. Imperial 44 was found slower to bolt than any other strain of the same type tested. As grown on well-decomposed muck soil, it had a much more spreading root system and fewer deep roots than White Boston, indicating a better feeding but possibly a poorer water-collecting capacity. Wider spacing than is usually allotted lettuce was needed to produce large heads of the Iceberg type. Too abundant feeding with too quickly available N made for poorer heading and greater susceptibility to tipburn. Water supply was apparently a vital factor, and a plentiful and relatively constant supply is considered essential for good heading. It is believed that water may be helpful in part by overcoming, to some degree, the detrimental effects of high temperatures. On most muck soils a water table of from 18 to 24 in. should provide sufficient moisture without saturating the soil. Suggestions as to fertilization on muck and mineral soil are given. Imperial 44, notwithstanding its susceptibility to tipburn and failure to head under extreme temperatures, is conceded the best variety of Iceberg lettuce yet introduced into the State.

The effect of temperature on the photoperiodic response of spinach, J. E. KNOTT (*[New York] Cornell Sta. Mem. 218 (1939), pp. 38, figs. 10*).—Although a complete interacting range of both temperature and photoperiod was not included in the study, the data suggested that for spinach the photoperiod may be less important than temperature in determining the reproductive response. The photoperiod necessary to cause the appearance of seedstalks was apparently determined by the temperature during early growth complemented by the temperature prevailing during the later stages of development. In the case of plants growing under a 15-hr. photoperiod and exposed to three temperature ranges, namely, from 50° to 60° F., 60° to 70°, and 70° to 80°, the 60°-to-70° lot was the earliest to initiate seedstalks. At from 40° to 50° and 15 hr. of light, plants made little growth, but when subjected to favorable temperatures they developed seedstalks sooner than did those plants not subjected to an initial low-temperature treatment. Under both the 15-hr. and the natural photoperiod, the higher the temperature at which the plants were growing the sooner after the completion of the initial treatments did the blooms appear. The rate of elongation of seedstalks was influenced by the prevailing sunshine, photoperiod, and temperature in descending order. The possible role of temperature in the production of a flower-promoting hormone is discussed. The fact that spinach exposed to a 7-hr. day at from 60° to 70° did not form seedstalks until March 14 following the planting on October 11 may have been due to the slow production of the hormone. The relation of the observations to the behavior of spinach in the field is indicated.

The modification of flower structure by environment in varieties of *Lycopersicum esculentum*, F. S. HOWELL. (Ohio Expt. Sta.). (Jour. Agr. Res. [U. S.], 58 (1939), No. 2, pp. 79-117, figs. 14).—A study of the flowers of fifty-odd varieties and strains of tomato showed a definite response to environment with respect to the relative length of the pistils and stamens. The change in relative length of the two organs was largely due to variation in the length of the pistil. The ovary, as well as the style, was concerned in change in the pistil length, but the style was usually the more important factor. Differences occurred among varieties as to the extent or degree to which the relative length of the pistils and stamens varied in response to environment. In certain varieties in which the pistil was enclosed within the staminal cone the effect of environment was masked. A classification of a number of varieties based on the relation of the length of pistils to that of stamens is presented. The maximum length of the pistils in relation to stamens was attained in plants grown during a period of relatively short daylight, under light of low intensity, and with an abundance of readily available N. On the contrary, short pistils in relation to stamens were produced when the days were long, the light of high intensity, and the supply of N only moderate. Increased length of pistils in relation to stamens is believed to be associated with, if not due to, carbohydrate deficiency. It is suggested that the differential response of the two sex organs is due to differences in their physiological mechanisms.

[Pomological studies by the Cornell Station], D. BOYNTON, A. J. HEINICKE, M. B. HOFFMAN, J. I. DEVILLERS, L. H. MACDANIELS, E. M. HILDEBRAND, A. B. BURRELL, D. S. WELCH, R. M. SMOCK, and A. J. LOUSTALOT ([New York] Cornell Sta. Rpt. 1938, pp. 138-143).—The following studies are discussed: Lack of oxygen in the soil atmosphere as related to apple tree rooting and productivity; influence of different kinds and amounts of mulch material on the growth and fruiting of apple trees; influence of fertilizer placement on the growth and fruiting of apple trees; growth and activity of roots of fruit trees under varying soil and cultural conditions; effect on the set of fruit of spraying and dusting apple blossoms with various fungicides and bactericides; wound dressings for fruit trees, with special reference to trees damaged by winter injury; the structure of the flowers of apple, pear, and quince, with special reference to the occurrence of stomata and the cutinization of various floral parts; effects of freezing on the roots and other tissues of fruit plants; relation of climatic, soil, and cultural conditions and maturity of apples to storage; comparative efficiency of oiled wrappers and shredded oiled paper and different waxes in the control of apple scald and shriveling; effect of different low but nonfreezing temperatures on the keeping quality of apples; effect of modified storage atmospheres on the keeping quality of apples; cause and control of bitter pit in apples; factors influencing the red color formation in fruits during and after harvest; removal of spray residue from cherries; and the photosynthetic activity of apple foliage under natural conditions and as influenced by cultural practices, with special reference to spraying and fertilization.

Soils in relation to fruit growing in New York.—XIV, Tree behavior on important soil profiles in the Finger Lakes area, D. BOYNTON ([New York] Cornell Sta. Bul. 711 (1938), pp. 21, figs. 20).—Continuing this series (E. S. R., 80, p. 593), a discussion is given on the growth of apple and cherry trees on different types of soil. As indicated previously, soil conditions exert a profound influence on the tree and its roots. Trees on Ottawa loamy fine sand developed deep and extensive roots and vigorous tops. Dunkirk silty clay was also satisfactory where the surface drainage was good. Honeoye, Lansing and

Darien soils were adequately drained but were sometimes underlaid less than 3 ft. below the surface with an extremely compact, unweathered glacial-till subsoil. Ontario loam proved satisfactory in the area studied. Lyons silt loam showed slow internal drainage and compact, shallow subsoil distinctly unfavorable to the Rhode Island Greening apple. Where Lansing and Darien soils were underlaid with bedrock closer than 3 ft. to the surface, growth of trees was reduced and mortality became a factor. In the very dry summer of 1936 sweet cherries on this type of soil suffered serious losses. The importance of examining soils prior to setting out orchards is stressed.

[Leaflets on fruit growing] (*U. S. Dept. Agr. Leaflets 170 (1939), pp. 8; 172, pp. 5; 173, pp. 5, figs. 4; 178, pp. 8; 179, pp. 6*).—General information is presented on the following subjects: Nos. 170, Date Growing in the United States, by R. W. Nixon and D. C. Moore; 172, Why Fruit Trees Fail to Bear, by H. P. Gould; 173, The Bud-Graft Method of Propagating Vinifera Grape Varieties on Rootstocks, by E. Snyder and F. N. Harmon; and 178, Dwarf Fruits, and 179, The Native Papaw, both by H. P. Gould.

The storage of sweet cherries as influenced by carbon dioxide and volatile fungicides, F. GERHARDT and A. L. RYALL (*U. S. Dept. Agr., Tech. Bul. 631 (1939), pp. 20*).—An increase in the CO₂ content of the storage atmosphere was found effective in prolonging the useful life of freshly harvested sweet cherries. Bing and Lambert varieties were held without impairment of dessert quality for 12 days at 60° F. in 40 percent, 20 days at 45° in 40 percent, or 31 days at 32° in 10 percent of CO₂. Since satisfactory mold control was obtained at 45° in 25 percent of CO₂, concentrations of 40 percent supplied a wide margin of safety. At 60° or above, CO₂ storage in concentrations sufficient to inhibit mold formation impaired flavor. In firmness, brightness, and freedom from decay, gas storage at 45° and 20 percent of CO₂ up to 20 days was found preferable to air storage at 32°. Surface pitting was reduced by storage in atmospheres containing 15 and 25 percent of CO₂.

Of various volatile chemicals used for impregnating packaging materials, elemental iodine alone showed any promise. Fruit flavor was not altered by the use of iodine wraps, but when used in sufficient concentrations to control decay there resulted lenticel injury and surface pitting, particularly in the light-colored Napoleon. Iodine injury was less apparent in fruit stored at 45° than at 65°. The use of iodine in connection with CO₂ storage is not warranted since the CO₂ alone was adequate to control decay. None of the organic compounds carrying iodine were as effective fungicides as iodine alone. The possibility of using CO₂ at transit temperatures during freight shipments of cherries is discussed.

The Northstar strawberry, G. M. DARROW (*U. S. Dept. Agr. Circ. 517 (1938), pp. 2, fig. 1*).—Originated as a cross between Howard 17 and Redheart, this new variety is introduced for growing in the northern United States. The plants are productive and the fruit is large, firm, and of high dessert quality.

Correlations between size of seed, seedling, and nursery tree in the avocado, B. W. HOBSON and E. R. EGGERS. (*Univ. Calif.*). (*Calif. Avocado Assoc. Yearbook, 1938, pp. 92-96, fig. 1*).—Further statistical studies (*E. S. R., 80, p. 347*) of the seeds and resulting seedlings showed that under like conditions large seeds tend to produce large seedlings, and vice versa. When budded with known varieties the large seedlings tend to produce larger nursery trees. Trees resulting from the autumn start of buds were larger and more uniform than those started in the spring.

Water content of avocado fruit and leaves, A. R. C. HAAS. (*Calif. Citrus Expt. Sta.*). (*Calif. Avocado Assoc. Yearbook, 1938, pp. 97-102, figs. 2*).—Data

taken on fruit and leaves of three varieties, Fuerte, Dorothea, and Puebla, showed varietal and seasonal differences in moisture content. Throughout most of the season the water content of the pulp was greater in Fuerte than in Dorothea fruits, but about the first of February the water contents of all three were almost alike. The percentage of water content in Fuerte seeds was usually greater than in the other two varieties. As to leaves, there was noted, in samples collected January 12, a relatively high water content in varieties usually known to be tender.

A promising method for distinguishing between Mexican and Guatemalan avocado bark, F. F. HALMA and E. R. EGGERS. (Univ. Calif.). (*Calif. Avocado Assoc. Yearbook, 1938, pp. 107, 108*).—When water was added to powdered bark, the bark of the Mexican group formed a coagulated or viscous mass, while that of the Guatemalan varieties remained more or less granular. Hybrids, such as Fuerte, behaved more like their Guatemalan parents.

[Ornamental horticulture at the Cornell Station], K. POST, E. P. HUME, M. W. NIXON, R. C. ALLEN, A. M. S. PRIDEHAM, J. C. SWARTLEY, and H. T. SKINNER ([*New York*] *Cornell Sta. Rpt. 1938, pp. 121, 122*).—Brief progress reports are given on the following studies: Photoperiodism of chrysanthemums, effects of increasing the length of day by the use of electric light of varying types and intensities upon the growth and time of flowering of greenhouse plants, conditions affecting the keeping of dahlia roots in storage, the culture of hardy bulbs, the propagation of conifers, and the propagation of rhododendrons and other ericaceous plants by cuttings.

House plants may be successfully grown if simple rules are carefully followed, W. E. GUNESCH (*Colo. Farm Bul. [Colorado Sta.], 1 (1939), No. 1, pp. 15, 16*).—Discussing the essential requirements for house plants, the author presents brief notes on the specific needs of various plants, including the begonia, Boston fern, cyclamen, poinsettia, primrose, etc.

FORESTRY

An introduction to American forestry, S. W. ALLEN (*New York and London: McGraw-Hill Book Co., 1938, pp. VIII+402, figs. [129]*).—The history and development of forestry in the United States is discussed from both the commercial and public viewpoints.

[Forestry studies by the Iowa Station], G. B. MACDONALD, B. B. SPROAT, and A. F. DODGE (*Iowa Sta. Rpt. 1938, pt. 1, pp. 146-148*).—Included are reports on studies relating to the growing of trees and other plants for erosion control and to estimating the growth of timber species.

[Forestry studies by the Cornell Station], R. F. CHANDLER, JR., J. N. SPAETH, M. AFANASIEV, and E. F. WALLIHAN ([*New York*] *Cornell Sta. Rpt. 1938, pp. 84, 85, 123-125*).—Included are brief progress statements on the following projects: The calcium requirements of different tree species; the influence of certain mineral fertilizers upon the composition and growth of forest trees; the influence of soil type upon the growth of black-locust plantations; management of second-growth forest types; improved practice in the production of forest planting stock of broadleaved timber-tree species; establishment, culture, and development of forest plantations; and the influence of forest trees on the occurrence and growth of the subordinate vegetation in the forest.

[Forestry investigations by the Pennsylvania Station], W. E. WHITE, H. O. TREBOLD, and D. D. STEVENSON (*Pennsylvania Sta. Bul. 367 (1938), p. 45*).—Brief reports are given on studies in the propagation of hardwoods, and the factors affecting the flow of maple sap.

Forest resources of southeastern Texas, J. W. CRUIKSHANK and I. F. ELDERIDGE (*U. S. Dept. Agr., Misc. Pub. 326* (1939), pp. VI+37, pl. 1, figs. 16).—Information is presented on physical features, character of the forests, contents of saw timber and cordwood, ratio of increment to drain, and special-use resources, such as naval stores and pulpwood.

Forest tree breeding technique, E. J. SCHREINER. (*U. S. D. A.*). (*Jour. Forestry*, 36 (1938), No. 7, pp. 712-715, figs. 6).—Procedure and equipment are described.

Underplanting hardwoods with pines, D. J. WEDDELL (*Alabama Sta. Rpt. 1937*, p. 30).—Data are presented on the comparative growth of several pines planted under hardwoods and in the open.

Soil-fertility standards for growing northern conifers in forest nurseries, S. A. WILDE. (*Wis. Expt. Sta.*). (*Jour. Agr. Res. [U. S.]*, 57 (1938), No. 12, pp. 945-952).—Knowing that recently cleared but not burned-over forest land, which had supported a mature or nearly mature stand of satisfactory growth, always produces at least one crop of vigorous nursery seedlings, the author studied 500 samples of soil collected beneath thrifty stands of *Pinus banksiana*, *P. resinosa*, *P. strobus*, *Picea glauca* (= *P. canadensis*), *Abies balsamea*, and mixed stands of *Acer saccharum*, *Tilia americana*, and *Betula lutea*. Soil collected from barren areas was also included as a basis of comparison. Data are presented with relation to pH values, silt and clay fractions, base exchange capacity, total nitrogen, nitrates, ammonia, available phosphorus and potassium, and replaceable calcium and magnesium. The soils from beneath the thrifty conifers showed an NPK ratio of about 1-2-5. Greenhouse studies showed that nitrogen content should not exceed 2-2-5. On the basis of the study, the author suggests moderation in the use of nitrogen salts on forest seedlings, with reliance on the appearance of the foliage as an indicator of nitrogen needs. Luxuriant vegetative growth may not indicate the most desirable status with respect to resistance to disease or unfavorable environments.

A resurvey of the demonstration prairie shelterbelts in Minnesota, H. L. HANSEN and H. SCHMITZ (*Minnesota Sta. Bul. 537* (1938), pp. 16, figs. 11).—Based on a partial resurvey (*E. S. R.*, 67, p. 687), it was found that the shelterbelts, now 14 yr. of age and exposed to a period of severe climatic conditions, had suffered serious losses but that certain species had withstood the trials much better than others. Available soil moisture was the most important limiting factor in survival. The four most successful species—green ash, boxelder, American elm, and caragana—showed an average of 45 percent or more of survival, with the green ash and boxelder approximating 70 percent. Green ash is recommended as the most satisfactory species of all tested. The tops of boxelder, willow, and, to some extent, American elm, were killed back during the severe drought. The evergreens showed a significantly lower survival on heavy clay soils than on lighter soils of a sandy nature. A total of 8 of the 64 shelterbelts examined were in need of light thinning, although none was seriously overcrowded. Two important causes of poor growth were grazing and a lack of adequate culture and care. In some cases tenant operation was a factor in the poorer results. In some localities rabbits caused considerable damage, especially to Scotch pine and Chinese elm by girdling the trunks and killing the lower branches.

Statistics of forest products in the Rocky Mountain States, R. V. REYNOLDS and A. H. PIERSON (*U. S. Dept. Agr., Statis. Bul. 64* (1938), pp. 29, fig. 1).—Data are presented on lumber production, distribution, consumption, and prices.

Forest products statistics of the Pacific Coast States, R. V. REYNOLDS and A. H. PIERSON (*U. S. Dept. Agr., Statist. Bul. 65 (1938), pp. 30, figs. 4*).—Data are presented on lumber production, distribution, consumption, and prices

Stampage and log prices for the calendar year 1937, compiled by H. B. STEER (*U. S. Dept. Agr., Statist. Bul. 66 (1939), pp. 61, figs. 3*).—Data are presented in the usual tabular form (*El. S. R., 78, p. 491*).

DISEASES OF PLANTS

Handbook of plant diseases, VI, founded by P. SORAUER (*Handbuch der Pflanzenkrankheiten. Berlin: Paul Parey, 1939, vol. 6, pt. 1, pp. XII+647, figs. 63*).—This part of the monograph series (edited by O. Appel, with the collaboration of H. Braun, W. Fischer, G. Hilgendorff, H. Klinger, [H.] Morstatt, E. Riehm, H. Thiem, W. Tomaszewski, W. Trappmann, and A. Winkelmann) covers the agricultural significance of plant protection; and the problems of plant protection, including the prevention of the appearance of plant diseases and pests (e. g., hygiene and quarantine) and their control by physical and chemical means.

[Abstracts of papers presented at the twenty-first annual meeting of the Pacific division of The American Phytopathological Society, 1937] (*Phytopathology, 27 (1937), No. 9, pp. 953-956*).—Abstracts of the following papers are given: Control of Peach Mosaic in Colorado (p. 954) and The Maynard Plum—A Carrier of the Peach Mosaic (p. 954), both by E. W. Bodine; Peach-Mosaic Host-Relationship Studies in Southern California, by L. C. Cochran and L. M. Hutchins (p. 954); History of *Elsinoe fawcettii*, the Causal Fungus of Citrus Scab [Including Synonymy], by A. E. Jenkins and A. A. Bitancourt (pp. 954, 955); A Vascular Rhizoctonosis of Sugar Beet (p. 955) and A *Phytophthora* [*capsici*?] Rot of Cucumber Fruit (p. 955), both by W. A. Kreutzer; A Tomato Resistant to Two Wilts [*Verticillium albo-atrum* and *Fusarium lycopersici*], by M. Shapovalov and J. M. Lesley (p. 955); Black Ring, A Virosis of Cabbage and Other Crucifers, by C. M. Tompkins, M. W. Gardner, and H. R. Thomas (pp. 955, 956); and The Infestation of Soil With *Ophiobolus graminis* and Its Subsequent Increase and Spread in the Soil (p. 956) and Effect of Climatic Conditions on the Prevalence of *Ophiobolus graminis* in the Soil (p. 956), both by H. Fellows.

Abstracts of papers presented at the 1938 meetings of the Genetics Society of America (*Genetics, 24 (1939), No. 1, pp. 72, 73, 78, 89*).—The following papers of interest to plant pathology are included: Behavior of Tobacco Mosaic Virus Irradiated With X-Rays of Different Wave Lengths, by J. W. Gowen, and Micro-evolution of Host-Parasite Interactions in Bacterial Wilt of Maize, by R. E. Lincoln and E. W. Lindstrom (both Iowa State Col.); and Fasciation—Its Characteristics, Distribution, Origin, Hereditability, Relation to Environment, and Plant World Analogy to Cancer, by O. El. White.

[Plant disease studies] (*Va. Acad. Sci. Proc., 1938, pp. 40, 41, 43, 45*).—Abstracts of the following papers are included: Influence of Temperature on the Development of the Tobacco Downy Mildew Disease, by R. G. Henderson (*Va. Expt. Sta.*); Effect of Four Years of Barberry Eradication on Stem Rust of Cereals in Virginia, by G. E. Matheny (*U. S. D. A.*); A *Fusarium* Disease of Spinach, by H. T. Cook and T. V. Nugent (*Va. Truck Sta.*); and Methods of Sterilizing Planted Soil, by R. G. Henderson, and An Improved Technique for Demonstrating Rust Hyphae and Haustoria in Unsectioned Leaf Tissue, by M. McBryde (both *Va. Expt. Sta.*).

The Plant Disease Reporter, March 1 and 15, 1939 (U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 23 (1939), Nos. 4, pp. 55-77, figs. 4; 5, pp. 79-88, fig. 1).—The following items are included:

No. 4.—*Cephalosporium* wilt of persimmon in the Southeast, by B. S. Crandall; spread of white pine blister rust in 1938 (with map and tabulated detail); *Fusicladium robiniae* and *Macrosporium* sp. in forest tree nurseries (with tabulated data), by W. C. Davis and R. W. Davidson; diseases of fruits and vegetables (apples, celery, grapes, olives, onions, oranges, peas, pears, peppers, pomegranates, squash, tangerines, and tomatoes) on the New York market during the months of October, November, and December, 1938, by J. S. Wiant and C. O. Bratley; symptoms of bacterial wilt and rot (bacterial ring rot) of potato (E. S. R., 80, p. 500); smutty wheat receipts continue decline, by B. W. Whitlock; smutty wheat trends downward on the Minneapolis market, by R. J. Haskell; six-year study shows when to expect freeze losses in winter wheat; brief notes on *Sclerotinia* stem blight on stocks in California, wheat rusts in Kansas, and cereal diseases in California; and new diseases or new distribution reported in the literature (discovery of citrus canker in New Zealand, a bacterial disease of stocks in New South Wales, and *Phytophthora* disease of hops in New Zealand).

No. 5.—Incidence and importance of quince rust (*Gymnosporangium clavipes*) on apple as affected by environmental and developmental factors, by P. R. Miller; tobacco downy mildew situation in Florida, by W. B. Tisdale and R. R. Kincaid; possible cause (*Curvularia lunata*?) of black kernels in rice, by A. L. Martin; adverse weather brings most loss to wheat crop; diseases of shade and ornamental trees—summary of specimens received in 1938 at the New Haven (Conn.) office, division of forest pathology, by A. M. Waterman; and brief notes on losses from corn ear rots in Illinois, *Thielaviopsis basicola* on geranium in Connecticut, and tobacco downy mildew in North Carolina.

[Plant disease studies by the Iowa Station]. (Partly coop. U. S. D. A.). (Iowa Sta. Rpt. 1938, pts. 1, pp. 103-109, 112, 113, 114, 115, 116, 117, 118, 146; 2, pp. 28, 29, 46-48, 52-59).—In part 1, brief reports are included on breeding and selection of better disease-resistant strains of watermelons, by G. Younkin and I. E. Melhus; parasitism of smuts, rusts, and minor diseases of oats, by H. C. Murphy; development of disease-resistant strains of oats, by Murphy and L. C. Burnett; control of seed- and soil-borne diseases of potatoes, by C. S. Reddy; pathogenicity, host response, and control of *Cercospora* leaf spot of sugar beets, by C. M. Nagel; development and testing of dust fungicides for controlling seed-borne diseases of wheat and oats, by Reddy; propagation of disease-free sweetpotato seed stock, by Melhus; seedling structure of wilt-resistant watermelons and the inheritance of fruit shape and flesh color by J. N. Martin; yellow dwarf and other onion diseases in Iowa, by G. N. Davis and Melhus; three apple diseases in Iowa, viz. cedar apple rust, apple scab, and root necrosis, by Melhus; plant pathology phases of barley breeding especially for scab resistance, by Reddy; influence of pythiaceae and other fungi on seedling stands of legumes and other crops, by Melhus, Reddy, and W. F. Buchholtz; breeding of sugar beets for disease resistance, by Melhus, Reddy, Buchholtz, and Nagel; identification and control of diseases of small ornamentals and fruit tree stocks in Iowa nurseries, by Melhus; diseases causing poor stands of flax in Iowa and their control, by Reddy; and control of white pine blister rust in Iowa, by G. B. MacDonald, C. J. Drake, and Melhus.

In part 2, brief reports are included on the development of laboratory technics for detecting seed-borne plant pathogens, by R. H. Porter; genetic investigations of bacterial wilt resistance in corn, by E. W. Lindstrom; physiological response

of the growing plant and the pathogen to chemical treatments of seed corn, by Reddy; fermentation products formed by the action of certain fungi on the byproducts of the corn plant, by J. C. Gilman, W. E. Loomis, and C. H. Werkman; factors influencing resistance of strains of corn to *Ustilago zeae*, by Melhus and Davis; *Diplodia zeae* dry rot of corn, by Melhus; pathogenicity of *Basisporium gallarum* to corn, by Reddy; measuring and combining disease resistance in corn, by Melhus; disease resistance (*Diplodia*) in corn—nature and methods of measuring, by Davis, Reddy, Melhus, Loomis, Lindstrom, and A. A. Bryan; and plant disease survey of Iowa, by Melhus, Reddy, Porter, and Davis.

[Plant diseases in Maine] (*Maine Sta. Bul.* 391 (1938), pp. 238-241, 258, 259, 288-304, 322, fig. 1).—Reports of progress are given on studies relating to apple scab control, by D. Folsom; strength of mercuric chloride solutions in treating seed potatoes, by E. R. Tobey and B. E. Plummer, Jr.; Green Mountain potato seed plats, and strain test with special reference to diseases, both by Folsom; spraying and dusting potatoes, including comparison of spray fungicides, the potato dump heap as a source of rust or late blight infection, and elimination of spraying by new [*Phytophthora*] rust-resistant varieties of potatoes, by R. Bonde; studies on the control of *Rhizoctonia*, including comparison of fall and spring as the time for seed treatment, soil infection, and the effect of applying chemicals to the soil in its control, by Bonde and L. Schaal; spread of virus diseases in 1937 in Aroostook County, by Bonde; and insects in the transmission of potato virus diseases, including the relation of roguing, and tests with the pink and green potato aphid and the peach aphid showing the effectiveness of the latter in the spread of leaf roll, by G. W. Simpson. An abstract of the following paper not previously abstracted is also included: Winter injury to ornamental woody plants in Maine (*E. S. R.*, 78, p. 56), by M. T. Hilborn.

Net necrosis of the potato, D. FOLSOM, W. C. LIBBY, G. W. SIMPSON, and O. L. WYMAN (*Maine Agr. Col. Ext. Bul.* 246 (1938), pp. 12, figs. 9).—A handbook on this tuber disease, due to the leafroll virus, and its control.

[Phytopathology at the Cornell Station] (*[New York] Cornell Sta. Rpt.* 1938, pp. 115, 128-131, 131-134, 135).—Reports of progress on investigations of the following subjects are included: The Dutch elm disease and its insect vectors and control, by P. A. Readio and D. L. Collins; scab, rhizoctoniosis, and pitting of potatoes, by F. M. Blodgett, C. F. Taylor, E. K. Cowan, and C. S. Tuthill; potato rotation in relation to diseases, by Blodgett, Tuthill, K. B. Nash, and E. N. McCubbin; apple mosaic or variegation, by Blodgett; permanent crop improvement with potatoes through the control of disease by developing immune or disease-resistant stocks, and effect of internal conditions of the potato plant in their relation to susceptibility to *Phytophthora infestans*, both by D. Reddick and W. R. Mills; virus diseases of potatoes, by V. L. Frampton, E. D. Hansing, and T. C. Watkins; biochemical and biophysical studies on the fire-blight fungus, by Frampton; control of onion mildew and of smut, both by A. G. Newhall; lime-sulfur and substitute fungicides for controlling apple scab in western New York, by W. D. Mills; cork, drought spot, dieback, and rosette of apple, and field testing of fungicides for apple scab control, both by A. B. Burrell and F. H. Lewis; strains of *Erwinia amylovora*, cause of fire blight, little-known and imperfectly understood stone fruit diseases (mosaics), and fire blight of apples, pears, and quinces, all by E. M. Hildebrand; a general study of the Dutch elm disease, by D. S. Welch, K. G. Parker, L. J. Tyler, S. Pope, W. L. White, Readio, and Collins; diseases of narcissus and other flowering bulbs, by F. A. Haasis and F. Weiss (coop. U. S. D. A.); and life-history and taxonomic studies on *Typhula* spp., especially those causing snow scald of cereals and grasses in the United States, by Whetzel, H. M. Fitzpatrick, and R. E. Rensberg.

Plant disease studies (Oklahoma Sta. [Bien.] Rpt. 1937-38, pp. 135-144).—Reports of progress are made on airplane spore-trap studies indicating that wheat leaf rust may come from the North, tests of dusting methods for wheat bunt control, and heat treatments proving effective in saving nursery trees from root knot, all by K. S. Chester; and gravity grading of delinted cottonseed promising better stands of cotton (E. S. R., 80, p. 355), by Chester and G. Tennyson.

[Plant disease studies by the Oregon Station] (Oregon Sta. Cir. 130 (1938), pp. 4, 15, 27, 30, 31, figs. 12).—Brief outlines of progress are given on studies of nursery diseases, including *Coryneum* blight of Berckman's and related oriental arborvitae and black mold and storage dieback (*Botrytis*) of roses; onion mildew control by copper oxide or malachite green; downy and powdery mildews, mosaic, and wilt of peas; and root nematode control, particularly with reference to potatoes and clover, which are reduced in yield and quality by this pest.

[Plant disease studies by the Pennsylvania Station] (Pennsylvania Sta. Bul. 367 (1938), pp. 31, 32, 33, 34, fig. 1).—Brief outlines of progress are included on sprays for control of scab and codling moth on apples, by H. W. Thurston and H. N. Worthley; fire-blight-resistant pears, by E. L. Nixon; barberry eradication for control of black rust of oats, by F. D. Kern; control of fungus diseases of mushrooms, by W. S. Beach; potato breeding for quality, yield, and disease resistance, by Nixon; culture method of identifying fungi of wood decay; method of determining adhesiveness of insecticide-fungicide sprays, by D. E. H. Frear and H. J. Miller; and factors influencing tobacco wildfire, transmission by flea beetles, and control by sprays, by W. S. Beach.

[Plant disease studies by the South Carolina Station] (South Carolina Sta. Rpt. 1938, pp. 54-61, 63, 129-131, 186-188, figs. 2).—Reports of progress are included on studies of *Fusarium vasinfectum* wilt of cotton, by G. M. Armstrong and R. Weindling; the effect of mineral nutrition on the wilt resistance of a resistant and a susceptible cotton variety, by W. B. Albert, W. B. Keller, and Armstrong; cottonseed treatment, by C. H. Arndt; a plant disease survey; tobacco downy mildew (blue mold) treatments, by W. M. Lunn and J. R. Mattison; and control of downy mildew of cucumbers and cantaloups by fungicidal dust treatments, by C. J. Nusbaum.

[Phytopathology at the Texas Station]. (Partly coop. U. S. D. A.). (Texas Sta. Rpt. 1937, pp. 22, 23, 84-86, 93, 94, 95-107, 107-115, 115-121, 175, 193-196, 206, 209, 210, 248, 244, 281-284, 293, 294, 301, 302, 303).—Reports of progress are given by various Texas Station workers (including G. E. Altstatt, I. M. Atkins, D. C. Bain, G. T. Boyd, L. E. Brooks, A. L. Burkett, W. N. Ezekiel, G. S. Fraps, J. F. Fudge, G. H. Godfrey, A. L. Harrison, S. S. Ivanoff, M. J. Janes, D. T. Killough, E. W. Lyle, C. H. McDowell, E. S. McFadden, G. T. McNess, P. Macy, P. C. Mangelsdorf, H. F. Morris, C. H. Rogers, J. N. Roney, J. J. Taubenhaus, K. W. Wang, G. M. Watkins, R. H. Wyche, and P. A. Young) on studies of root rot; breeding small grains resistant to rust; cotton root rot in Texas in 1937, conditions affecting its local prevalence, life history studies of the fungus (*Phymatotrichum omnivorum*), and some Basidiomycetes found associated with it; studies on the basis of immunity in monocotyledonous plants to *Phymatotrichum* root rot; variation and dissociation within the root-rot fungus; growth of *P. omnivorum* on decoctions prepared from roots of various woody plants; cytology of *P. omnivorum* and of the host parasite relations in field infections by it; strand formation in *P. omnivorum*; growth of *P. omnivorum* in soils to which various amounts of crude petroleum had been added; barriers to prevent spread of root rot; relation of soil acidity to cotton root rot; regional cotton variety *Fusarium* wilt study at College Station and at Jacksonville; effect of foliage dusts and sprays on the yield

and control of foliage diseases of cotton; tomato disease studies (including seed carriers of *Fusarium* wilt, viability of *F. lycopersici* in the dead dry host, the population of *Fusaria* in wilt-infected soil, varietal tests for wilt resistance, isolation of *F. lycopersici* from wilted plants from different parts of Texas, control of damping-off by seed treatments, control of post-emergence damping-off, the cost of an electrically heated hotbed and coldframe, wind injury of tomato seedlings, a method of disinfecting and preserving hotbed frames, control of soil-borne fungus diseases by chemicals, effect of various sprays for controlling foliage diseases, and virus diseases of tomato in southwest Texas); control of *Heterodera marioni* in vegetable crops; viability of sclerotia of *Sclerotium rolfsii*; rose diseases (including overwintering of fungi associated with dieback, life history studies on dieback, dieback inoculations, field control of dieback and of black spot, effect of fungicides on spore germination of the black spot fungus—*Diplocarpon rosae*, viability of black spot fungus spores, studies on spreader materials for rose fungicides, the effect of weathering on the toxicity of copper sprays to *Actinonema rosae* spores, leaf streak disease—probably virus induced, preparations for histological work on rose diseases, an unidentified cane disease, and *Gloeosporium* black canker); garlic diseases (including their prevalence, 1936-37, the effect of a "mosaic" condition of the leaves, the effect of weevil infestation, the effect of bacterial and fungus rots on the seed pieces—cloves—and the control of these organisms, and variety studies in relation to disease resistance); rice diseases (including organisms associated with discoloration of the kernels); the toxicity of fungicides (including the effect of fungicidal dusts and of sulfuric acid on the germination of spores of various plant pathogens, the effect of aging on the toxicity of Cuproside and other fungicidal dusts, the effect of various fungicidal chemicals on the growth of damping-off organisms in pure culture, and sulfuric acid treatment for various periods of time as affecting the survival of *Bacterium* (= *Phytomonas*) *malvacearum* and other organisms in cottonseeds); control of damping-off of seedlings (including the effect of chemical seed and soil treatments on damping-off and other diseases the effect of various seed treatments on the viability of cottonseed and their relation to seedling diseases, chemical seed treatment aiding fall production of bush beans, and seed treatment for carrot, beet, pea, and turnip seeds); miscellaneous disease studies (including the control of strawberry chlorosis, sulfur in controlling potato scab, stinking smut of wheat in Baylor County, sorghum root and crown rot, and the effect of foliage dusts on yield of peanuts); and a list of some 63 plant diseases not previously reported in Texas. Work on rose diseases at the Tyler Substation included field control of black spot and dieback, streak disease, *Gloeosporium* cane canker, and an unidentified cane disease. Cotton root rot investigations at the Temple Substation included the effects of 4-yr. rotations of cotton, oats, sorghum, and corn, of different 2-yr. rotations, of clean fallow and continuous cotton following clean fallow, and of continuous sorghum on number and viability of *Phymatotrichum omnivorum* sclerotia, the effect of 7 yr. clean fallow on root rot and yield of cotton, the effect of continuous sorghum on root rot, the residual effect of different chemicals and previous crop on cotton yield and on root rot, the effect of copper, iron, and mercury on the growth of the root rot fungus in solution cultures, analysis of cottonseed from green plants and from plants killed by root rot at different dates, resistance tests of cowpeas and cotton, and brief notes on miscellaneous crop plant diseases. Wheat diseases at the Denton Substation are noted, including stem rust, bunt, and loose smut. Attempts to control soil-borne tomato pathogens at the Nacogdoches Substation are reported. Studies at the Weslaco

Substation are reported relative to citrus disease control, including gummosis and wood rot, chlorosis, and fruit rots and blemishes; dill leaf and stem blight (second report in America); *Macrosporium carotae* leaf blight of carrot; *Pucciniopsis caricae* leaf blight of papaya; cotton root rot and seedling diseases; control of *Sclerotium rolfii* on Dutch iris; *Basidiophora entospora* downy mildew of aster; sweet pea mildew control; and root knot nematode control and the susceptibility of *Trigonella foenum-graecum* to it. Root rot studies at the Iowa Park Substation are reported relative to sorghum as a root rot remover, cotton from X-rayed seed in the attempt to obtain resistant selections, and the comparative resistance of grape stocks. Studies at the Winter Haven Substation are reported relative to a general survey of plant diseases in the Winter Garden area, and the control of eggplant yellows, apparently due to a virus and insect-transmitted.

Virus diseases and viruses, P. P. LAIDLAW (*Cambridge, Eng.: Univ. Press, 1938, pp. 52*).—This is a lecture summarizing the present status of bacteriophages, and of the viruses of both plant and animal disease.

Properties of virus proteins, W. M. STANLEY and H. S. LORING (*In Cold Spring Harbor Symposia on Quantitative Biology, VI. Cold Spring Harbor, N. Y.: Biol. Lab., 1938, vol. 6, pp. 341-360, figs. 9*).—This is a critical analytical review (63 literature references) including the work of the authors.

Inhibition of virus activity by insect juices, L. M. BLACK (*Phytopathology, 29 (1939), No. 4, pp. 321-337, figs. 6*).—Juices of the insect vectors *Aceratagallia sanguinolenta*, *Aedes aegypti*, *Aphis rumicis*, *Eutettia tenellus*, *Macrosiphum pisti*, *M. solanifolii*, *Macrosteles divinus*, and *Myzus persicae* were found to inhibit the infectivity of tobacco mosaic virus for Early Golden Cluster beans. Juices of macerated clover leafhoppers (*Aceratagallia sanguinolenta*) inhibited the infectivity of plant juices containing the viruses of potato yellow dwarf, tobacco mosaic, potato X, turnip mosaic, tobacco necrosis, or tobacco ring spot No. 1 when insect juice-virus mixtures were inoculated to suitable test plants. The infectivity of certain mixtures of tobacco mosaic virus and clover leafhopper juice could be increased by dilution or by heat treatment. The inhibitor in clover leafhopper juice proved to be thermolabile, not readily dialyzable, and unstable in acid or alkaline solution. If the inhibitor is a protein, as seems probable, it is very active, since 0.15 mg. of clover leafhoppers, containing only about 0.0015 mg. of soluble protein nitrogen, reduced the infectivity of 1 cc. of a solution of tobacco mosaic virus by 50 percent. A given concentration of inhibitor in the presence of different concentrations of tobacco mosaic virus reduced the number of primary lesions in beans by approximately a constant percentage. Tobacco mosaic virus was not destroyed by the inhibitor in clover leafhopper juice. The virus and the inhibitor were separated by subjecting mixtures of the two either to ultrafiltration or to ultracentrifugation.

Some Fungi Imperfecti from the Pacific Northwest, R. SPRAGUE and W. B. COOKE. (*Oreg. Expt. Sta. and U. S. D. A.). (Mycologia, 31 (1939), No. 1, pp. 43-52, figs. 2*).—Includes new taxonomy in the genera *Naemosphaeria*, *Placosphaeria*, *Robillarda*, *Heteropatella*, *Septoria*, and *Macrosporium*.

The genus *Cordyceps* in central Pennsylvania, L. O. OVERHOLTS. (*Pa. Expt. Sta.*). (*Pa. Acad. Sci. Proc., 12 (1938), pp. 68-74, figs. 9*).—The six species known for the State are described and figured, with local notes.

Growth and metabolism of *Fusarium lini*, A. K. ANDERSON (*Pennsylvania Sta. Bul. 367 (1938), p. 8*).—The growth-stimulating effect of the carcinogenic hydrocarbon 1,2,5,6-dibenzanthracene on *F. lini* is briefly referred to.

Isolation of *Phytophthora* spp., L. J. KLOTZ and H. S. FAWCETT. (*Calif. Citrus Expt. Sta.*). (*Phytopathology, 29 (1939), No. 3, pp. 290, 291*).—*P. citro-*

phthora or *P. parasitica* were easily isolated from contaminations on citrus by thorough washing of infected material, supporting it on hardware cloth at the top of a glass container and allowing it to set in but not completely covered by running water for three or more days, thus enabling the fungus to grow and develop sporangia. The material is then removed, freshly picked tree-ripe or silver-stage lemons are placed on or near the specimens, and the swim spores are induced to form by replacing the tap water with water at 15° C. Lemons thus infected by zoospores are allowed to decay, and the desired *Phytophthora* sp. is recovered by transferring the seeds aseptically to agar media.

Forced ejection of ascospores from apothecia of *Sclerotinia* species, L. D. LEACH and W. B. HEWITT. (Univ. Calif.) (*Phytopathology*, 29 (1939), No. 4, p. 373).—Ascospores of *S. sclerotiorum* and a brown rot form were forcibly ejected when apothecia were exposed to the vapors over alcohol-formalin-acetic acid-fixing solution. The method is recommended for trial when an abundance of ascospores is wanted.

Contribution to knowledge of the genus *Taphrina* in North America, W. W. RAY. (Cornell Univ.). (*Mycologia*, 31 (1939), No. 1, pp. 56-75, figs. 23).—Species on *Alnus* and on *Prunus* were studied and four new species are described.

New hosts for the aecidial stage of *Uromyces graminis* (Niessl) Diet., B. D'OLIVEIRA (Bol. Soc. Broteriana, 2. ser., 13 (1938), pp. 81-89, pls. 2).—The author claims to have established the relationship of *Aecidium foeniculi* (= *A. umbelliferarum*) to *U. graminis* on *Melica ciliata* and the heterothallism of the fungus. Sporidia were successfully inoculated into 15 species of 12 umbelliferous genera.

Powdery mildews of peach and rose, C. E. YARWOOD. (Univ. Calif.). (*Phytopathology*, 29 (1939), No. 3, pp. 282-284, fig. 1).—*Sphaerotheca pannosa* forms on peach and on rose proved to be morphologically distinct in their conidial stages, and each was found to overwinter in infected buds. Conidia from peach mildew made considerable growth on rose leaves, but no growth of rose mildew on peach leaves was noted. Peach mildew was more luxuriant on leaf curl-infected than on noncurled leaves of ornamental peaches.

Control of powdery mildews with a water spray, C. E. YARWOOD. (Univ. Calif.). (*Phytopathology*, 29 (1939), No. 3, pp. 288-290).—Control tests with water at a pressure of 70 lb. and applied late in the afternoon to combat the powdery mildews of euonymus, rose, bean, cucumber, and barley resulted in a marked reduction as compared with comparable unsprayed controls. On the roses, which were also infested with red spider, 1 percent of the treated leaves remained infested with this pest as compared with 13 percent on the controls.

Colchicine in the prevention, inhibition, and death of plant tumors, N. A. BROWN. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 3, pp. 221-231, figs. 2).—Using different methods of applying colchicine, tumor formation was successfully prevented in only a few cases. However, brushing the surfaces of bacterial tumors once with a colchicine-lanolin mixture proved effective for inhibiting further growth and in time killing them. Of the total of 305 tumors, 239 died after such treatment, but none of the 49 tomato tumors included in this number succumbed. Other parts remained normal throughout the life span of the plants. Similar treatment of indoleacetic acid tumors with 2 percent colchicine solution inhibited further growth though failing to kill the tumors, but stronger solutions have not yet been tested.

Relation of particle size and color to fungicidal and protective value of cuprous oxides, J. W. HEUBERGER and J. G. HORSFALL. (N. Y. State Expt. Sta. et al.). (*Phytopathology*, 29 (1939), No. 4, pp. 303-321, fig. 1).—Using a

technic described for the rapid measurement of particle size of cuprous oxide suspensions, a series of powders ranging in color from red with particle size 2.57μ and wavelength 6,440 a. u. through orange to yellow with particle size 0.94μ and wavelength 5,950 a. u. was assembled. The fungicidal value (ability to inhibit spore germination) was tested in the laboratory with spores of *Macrosporium sarcinaeforme* and the protective value (ability to prevent infection) in the greenhouse and field by the usual seed and foliage technic against *Pythium ultimum*, *Diplocarpon rosae*, and *Alternaria solani*. As the particle size and wavelength of reflected light decreased, the fungicidal and protective values were found to increase. As the color is a function of particle size it thus becomes possible to forecast the probable field performance of cuprous oxides from their color. The probable explanation for the increased fungicidal and protective values of cuprous oxides of small particle size appears to be that the area of chemically reactive surface per unit of weight and the rate at which soluble copper is presented to the germinating spore are increased. It is deemed noteworthy that the field and greenhouse results paralleled those of the laboratory tests.

Black ring, a virus disease of cabbage and other crucifers, C. M. TOMPKINS, M. W. GARDNER, and H. R. THOMAS. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 57 (1938), No. 12, pp. 929-943, figs. 6).—Under study since 1932 (see p. 47), this virus disease is said to occur chiefly in the cool, coastal valleys of California during winter but to be uncommon in summer, and to cause marked injury to the older, outer leaves. Chlorotic lesions, many of them becoming partially or entirely necrotic with age, are characteristic, and the symptoms are most conspicuous on the lower leaf surface. Under glass the virus was transmitted to healthy cabbage by the cabbage and green peach aphids, and it was also readily transmitted by juice inoculations with powdered carborundum. The virus was inactivated between 57° and 59° C., withstood aging in vitro at 22° for 48 hr., and tolerated dilution at 1-700. All cabbage varieties tested were susceptible. Among the Cruciferae, systemic infection was obtained on kale, Brussels sprouts, sprouting broccoli, kohlrabi, turnip, pe-tsai, charlock, dames violet, cauliflower, rape, rutabaga, leaf or Chinese mustard, white mustard, *Brassica adpressa*, shepherds-purse, wallflower, Brompton stock, water cress, Chinese radish, evening scented stock, annual stock, and honesty. Infection was also obtained on plants of 11 other families, viz, rhubarb, lambsquarters, sow-bane, spinach, chickweed, mignonette, fibrous-rooted begonia, garden verbena, petunia, Iceland poppy, *Nicotiana glutinosa*, *N. langsdorffii*, *N. tabacum*, mourning bride, annual marguerite, zinnia, winter Cape-marigold, cineraria, and forget-me-not.

The effect of some soil factors on *Penicillium* injury of corn seedlings, S. DIAOHUN. (Ky. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 3, pp. 231-241).—Wounded corn kernels inoculated by immersion in a spore suspension of *P. oxalicum* and planted with the wound pressed into contact with very wet soil were less injured by the fungus than when similarly inoculated kernels were planted in loose wet or dry soil. *P. notatum* and an unnamed species from a diseased ear in the field offered wounded kernels partial protection against infection by *P. oxalicum* from the soil, though no antagonism among these species and *P. oxalicum* was noted in culture. A substance toxic to corn seedlings was produced on Richard's solution and on autoclaved and living kernels by *P. oxalicum* but not by the other two *Penicillia*.

1938 sweet corn wilt tests (New Jersey Stas. Plant Disease Notes, 16 (1938), No. 8, pp. 25-29).—Tests were conducted at five points in New Jersey. At Moorestown, where wilt was severe enough to give reliable data on resistance,

among 13 varieties Whipcross P39, Whipcross C62, Golden Cross Bantam, Bancross P39, and Charlevoix C2 gave the best yields and the first three proved to be very resistant to wilt (*Aplanobacter stewartii*=*Phytophthora stewartii*). Seneca Golden was extremely susceptible and gave the poorest yield. A summary of the performance of 45 varieties and strains planted at New Brunswick, as to wilt, smut, yield, etc., showed that Early Bancross P39, Whipcross P39, and Golden Cross Bantam again stood at the top rank. Among the very early types, Marcross 13-6, as in 1937, proved to be highly resistant.

Relation of soil moisture to Fusarium wilt of cotton, W. H. THARP and V. H. YOUNG. (U. S. D. A. and Ark. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 1, pp. 47-61, figs. 4).—The effect of relative soil-moisture content on this cotton disease was studied under glass, using the susceptible Harper Mebane variety in all tests except one where the resistant Rhyne Cook was used. The soil was a silt loam, high in available nitrogen and phosphate but low in available potash, with a pH of 6.52 and a water-holding capacity of 37.7 percent of the oven-dry weight, and was from a field previously showing severe wilt and potash hunger. Soil moistures at 20-100 percent saturation were used in the tests—three at prevailing greenhouse temperatures (records shown) and one each at constantly maintained soil temperatures of 23°, 26°, 29°, and 32° C.

In all cases the susceptible variety exhibited a positive disease correlation with rise in moisture to an optimum at 80-90 percent saturation and a negative correlation with increase to 100 percent. For the resistant variety there was but little correlation of actually wilted plants with the soil-moisture level. Total-infection measurements indicated an irregular disease increase with rise in soil moisture over the entire range employed. The pH value of the inoculated soil at the different moisture levels became readjusted, until at the end of two experiments it exhibited a positive correlation with the soil-moisture content. In both cases the moisture level producing the highest disease had caused but little readjustment from the original pH 6.52.

"The data obtained at the four constant soil temperatures indicate the possibility of an interrelated influence of soil moisture and soil temperature on the disease. The correlative change in acidity with increase in soil moisture indicates that there may be other interrelated effects of different phases of the disease environment."

The occurrence of the perfect stage of Rhizoctonia solani in plantings of diseased cotton seedlings, A. J. ULLSTIEP. (U. S. D. A. and S. C. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 4, pp. 373, 374, fig. 1).—Basidia, sterigmata, and basidiospores identified as those of *Corticium vagum* developed in plantings with mycelium of *R. solani* from diseased cotton seedlings. The complete life cycle was obtained only when multispore transfers were used to seed plates of tap-water agar.

Purification of Nicotiana virus 6 protein, H. H. THORNBERRY and H. H. MCKINNEY. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 3, pp. 250-260, fig. 1).—*Nicotiana virus 6* (causing mild dark green mosaic of tobacco) was purified from crude plant juice by crystallization at pH 4.5 and 0.3 saturation of $(\text{NH}_4)_2\text{SO}_4$. The infectivity of the diseased plant juice was associated with a protein resistant to tryptic digestion. Analysis of the dialyzed protein indicated 13.28 percent N, no P, and 0.16 percent S, while nondialyzed protein contained 11.9 percent N, 0.33 percent P, and 1.33 percent S. Under dark field the unit crystals of protein were elliptical particles measuring $0.3\mu-0.5\mu \times 0.3\mu-1.6\mu$, while unit crystals of *Nicotiana virus 1* protein were needlelike, $0.4\mu-0.5\mu \times 3.2\mu-4.2\mu$. Both virus proteins on standing aggregated into threads or bundles of

unit crystals. *Nicotiana* virus 6 protein was dispersed at pH 7.5 to the degree of no visible particles and precipitated at pH 4.5 into elliptical crystals. At intermediate pH values the size and number of precipitated particles were directly proportional to the acidity. At pH 7.5 and in the presence of trypsin the protein was precipitated into typical crystals.

Ergot of Paspalum, C. L. LEFEBVRE (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 4, pp. 365-367).—Observations and artificial inoculations (2 yr.) indicated that several *Paspalum* species not previously reported as hosts of *Claviceps paspali* are susceptible to the parasite, the following apparently being new hosts: *P. urvillei*, *P. longipilum*, *P. pubescens*, *P. pubiflorum*, *P. ciliatifolium*, *P. langei*, and *P. intermedium*. On the other hand, the following species of this grass genus were repeatedly but unsuccessfully inoculated in the field: *P. notatum* (narrow-leaf type from Paraguay, and common local type from Georgia), *P. litidum*, *P. malacophyllum* (strains from Tifton, Ga., and Gainesville, Fla.), and *P. supinum*.

The Mycosphaerella disease of winter peas, and diseases of winter peas and vetches caused by Ascochyta species, J. L. SEAL (*Alabama Sta. Rpt.* 1937, pp. 24, 25).—This is a progress report on studies of these diseases and their control.

Verticillium wilt of pepper, Capsicum annuum, W. C. SNYDER and B. A. RUDOLPH. (Univ. Calif.). (*Phytopathology*, 29 (1939), No. 4, pp. 359-362, fig. 1).—A fungus wilt of pepper having been recently reported from California and Connecticut (E. S. R., 78, p. 491) in association with a *Verticillium*, the authors tested the pathogenicity of the California isolate, demonstrating clearly the susceptibility of *C. annuum* to this pathogen, identified as *V. albo-atrum*. Tomatoes grown in pots following infected peppers developed no aerial symptoms after 4 mo., but the fungus was recovered from a number of the side rootlets. It is suggested that possibly *Verticillium* rather than *Fusarium* may have been the cause of some of the vascular mycosis of peppers formerly attributed to the latter fungus.

[Potato diseases in Colorado] L. W. DURRELL and C. H. METZGER (*Colo. Farm Bul. [Colorado Sta.]*, 1 (1939), No. 1, pp. 3, 7, 8, 13, 14, figs. 2).—A note, with description of symptoms, is given by Durrell (pp. 3, 7, 8) on the new wilt and tuber rot related to the German "ring rot" and said to have been prevalent over a large number of Colorado potato fields during the 1938 season. The disease is tuber-borne, and all varieties are said to be susceptible. A sharp lookout for cases and the utmost care in "seed" selection are advised. An article by Metzger (pp. 3, 13, 14) discusses the 1938 season and its effect as regards the seed situation in 1939.

The infection of potato roots by Heterodera schachtii, A. R. GEMMELL (*Phytopathology*, 29 (1939), No. 3, pp. 287, 288).—The nematode larvae are said to be very easily detected in potato roots stained in 2 percent alcoholic iodine followed by destaining in alcohol to clear. Using this method on root tips of the same length (hence of about the same age), it was shown that, with other conditions comparable, the crop yield is directly related to the percentage of root tips infected at the early growth stages.

A study of suberin and suberized deposits of diseased potato tubers, L. M. HILL (W. Va. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 3, pp. 274-282, figs. 4).—The author presents methods for determining the difference between suberin and suberized deposit in lesions of potato tubers affected with several diseases. The petrographical microscope was used along with various microchemical tests to determine the presence of suberin and cellulose in the cell walls. The suberin was anisotropic in normal and wound periderm and in

corky cells surrounding the necrotic areas. The suberized deposit was isotropic and laid down on, or perhaps infiltrated in, a cellulose matrix and the result of oxidation and condensation of cell sap drying on the cellulose walls of cells associated with wound periderm and with necrosis in the tuber. The suberized deposit was studied in blue stem, purple-top wilt, net necrosis, hollow heart, stem-end browning, and in potato tissue invaded by *Fusarium avenaceum*. In all these cases this deposit had the same chemical and physical properties. Cutin was not associated with necrosis in the diseased potato tubers. Only a small amount of suberized deposit was associated with hollow heart as compared to that with wound cork. The cork cambium formed in hollow heart was spongy, while that of normal periderm was not. The suberized deposit always masked the anisotropic properties of starch, cellulose, and suberin. Phenol was associated with the suberized deposit, but was absent in suberin and in cellulose walls. Suberin and cutin are length-fast and cellulose is length-slow. Optical properties distinguishing cutin, suberin, suberized deposits, and cellulose proved useful in studying the necrotic lesions.

A mosaic disease of radish in California, C. M. TOMPKINS. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 2, pp. 119-130, figs. 5).—The symptoms of a mosaic disease of radish in the San Francisco Bay section California, are described as consisting at first of irregular-shaped, chlorotic lesions later developing into a coarse mottle, while on older plants the normal, dark green tissue appears as irregularly shaped, nonraised islands on a yellowish-green chlorotic background. Mechanically, the virus was readily transmissible with an incubation period of 9-18 days, but greenhouse attempts to transmit it by cabbage, green peach, or turnip aphids failed. The virus was infective after 14 days at 22° C., was inactivated by heating for 10 min. at 68°, but caused infection at 1:14,000 dilution. It is compared with certain other crucifer viruses. The host range was found to include 20 species of 9 genera in 4 families. In the Cruciferae, infection was obtained on *Brassica pe-tsai*, kale, Brussels sprouts, cabbage, sprouting broccoli, cauliflower, kohlrabi, black and white mustard, evening scented stock, Virginian stock, turnip, Chinese mustard, Chinese radish, and weeds, but annual stock proved resistant. Other susceptible hosts included lambsquarters, sowbane, spinach, rocket larkspur, *Nicotiana glutinosa*, *N. langsdorffii*, *N. rustica humilis*, and Turkish and White Burley tobacco. No infection was obtained by mechanical inoculation in 51 species of 44 genera in 25 families.

Variation in *Sphacelotheca sorghi* (Link) Clinton, L. J. TYLER (*Minnesota Sta. Tech. Bul.* 133 (1938), pp. 48, figs. 10).—Germinating chlamydospores of the covered smut fungus of sorghums are described and illustrated. The associated cytological phenomena indicate a far greater variability and more deviation from normal type than hitherto supposed. Essentially, the life cycle was like that of several species of *Ustilago*. Using sporidial fusions and the Bauch test for determining sex in *S. sorghi*, evidence was obtained that the sexual compatibility of paired lines may be determined soon after inoculation. Segregation for sex factors was apparently complete in the first or second nuclear divisions of the germinating spore. Two sex groups were found, and the sex factors segregated in the 2:2 and 1:3 ratios. Some data indicated that there are more than two sexual compatibility groups. Four ratios of factor segregation for cultural characters (independent of segregation for sex characters) were found, viz, 2:2, 4:0, 3:1, and 2:1:1. Artificially cultured, *S. sorghi* comprises an indefinite number of cultural types differing in one or more cultural characters, which are discussed in detail. Nutrients appeared to affect the rate of sectoring, malt agar and plain sugar media plus nutrient salts ap-

pearing to induce sectoring. Some lines sectored abundantly, others only rarely. For more than a year 14 lines remained culturally constant when grown on potato-dextrose agar, but 8 of them produced one or more sectors of new cultural type when later grown on malt agar. Lines arising through intraspecific hybridization between monosporidial lines from different chlamydospores differed in pathogenicity as indicated by stunting, color of peridia, size and hardness of smut balls, size of chlamydospores, and length of time required for chlamydospore germination. A bibliography of 47 entries is included.

Curly-top-resistant sugar-beet varieties in 1938, F. V. OWEN, F. A. AREGG, A. M. MURPHY, B. TOLMAN, C. PRICE, F. G. LARMER, and E. CARSNER. (Coop. Calif., Utah, and Idaho Expt. Stas.). (*U. S. Dept. Agr. Circ. 513* (1939), pp. 10, figs. 2).—Use of resistant varieties is said to have removed much of the danger formerly threatening the destruction of the sugar-beet industry in parts of California, Colorado, Idaho, and Utah. The history of curly-top-resistant varieties is briefly reviewed. Since none of the previous varieties met the differing requirements of all localities where curly top is an important factor, the present work was undertaken to provide another step towards the goal of better regional adaptation of resistant strains. Selection of very resistant individuals from U. S. 1 has given rise to a number of resistant strains, and U. S. 12 was thus originated by mass selection. Under severe test conditions U. S. 12 yielded 10.52 tons per acre as compared with 7.09 tons for U. S. 33 and 1.6 tons for R. & G. Old Type. The bolting tendency in U. S. 33 and U. S. 12 is said to be too strong to permit fall and winter planting in California, while in U. S. 14 it is low. The curly top resistance of the last is about as in U. S. 1, but it is susceptible to downy mildew. These varieties are described, and other superior strains being developed are discussed. Growing of seed in mild climates by the overwintering-in-the-field method is said to be unsatisfactory with varieties low in bolting tendency and in all varieties it results in deterioration, but the method may be used in cold climates to produce stock seed and low-bolting varieties.

Studies on a cultural variant of *Rhizoctonia solani*, E. L. LECLEGG. (U. S. D. A. and Minn. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 3, pp. 267-274, figs. 3).—Comparison of a sector variant occurring in a sugar-beet isolate of *R. solani* with the parent culture indicated that hyphal diameters of the two cultures did not differ significantly. The parent culture grew faster on potato dextrose, dextrose, and methylene-blue media, but much slower on media high, medium, or low in nitrogen. The parent also grew faster on media containing 0, 1, and 5 percent sucrose, but at 10 and 20 percent sucrose the growth rate of the variant was more rapid. The radial growth of parent was greater than that of variant at 15°, 23°-25°, and 29°-30° C. The parent culture was more aggressive in causing root rot of large sugar-beet roots, while the variant caused more damping-off of sugar beets at 15° and 25°.

Downy mildew of tobacco in Brazil, F. A. WOLF (*Phytopathology*, 29 (1939), No. 3, p. 291).—The author reports *Peronospora tabacina* from Brazil, and refers to an early collection of *P. nicotianae* in Argentina.

Contribution to the knowledge of tobacco mosaic and its wild hosts in Brazil [trans. title], K. SILBERSCHMIDT and M. KRAMER (*Arq. Inst. Biol. [São Paulo]*, 9 (1938), pp. 1-20, pls. 4; *Ger. abs.*, pp. 17, 18).—The viruses from eight tobacco plants showing various stages of a disease of mosaic type, collected in the State of São Paulo and tested by inoculations, all proved to be true tobacco mosaic strains, differing only in relative virulence. On this basis the eight strains fell into three groups. The susceptibility of a series of wild Solanaceae, frequent as weeds in the vicinity of tobacco and potato fields, was tested by inoculation with tobacco mosaic virus. the following proving to be easily infected: *Solanum*

reflexum, *S. platentifolium*, *S. aculeatissimum*, *S. mammosum*, *S. atropurpureum*, *S. sisymbrium*, and *S. nigrum*. The symptoms on these hosts are described and in part illustrated. *S. variable* appeared to act as a carrier without itself exhibiting definite symptoms. The significance of the weeding out of wild solanaceous hosts for reduction in the incidence of mosaic in tobacco fields is discussed.

Virus protein of mosaic disease of tobacco, C. G. VINSON, D. K. McREYNOLDS, and N. S. GINGERICH (*Missouri Sta. Res. Bul.* 297 (1939), pp. 12, figs. 3).—The authors found that the virus readily separated in the crystallinelike form of Stanley when anhydrous solid Na_2SO_4 was added to the virus fraction after adjustment to pH 4. Most of the ash could be removed from this crystallinelike material by washing with dilute acetic acid. The N content was ± 16 percent, and P was present. All visible traces of the brown pigment normal to tobacco-plant juice could be removed from the purified fraction by shaking a phosphate dispersion with ether, the pigment being carried to the top as the droplets of ether rose. X-ray diffraction patterns (camera and procedure described) of this virus protein prepared by the Na_2SO_4 method were obtained, but they failed to agree very well with those obtained by Wyckoff and Corey (E. S. R., 78, p. 585) who used virus protein prepared by the $(\text{NH}_4)_2\text{SO}_4$ method of Stanley. There was no indication on any film of spacings greater than 14.3A, although spacings as great as $\pm 50\text{A}$ could have been detected. Wyckoff and Corey recorded six spacings greater than 14.3A. Spacings as low as 2.43A were obtained, in contrast to the smallest spacing of 3.39A recorded by Wyckoff and Corey. The absence of long spacings in virus protein prepared by the Na_2SO_4 method may indicate it to be composed of smaller molecules, and hence with a lower molecular weight than that studied by others. There are 19 literature references.

The effect of flue-curing on the infectivity of ordinary tobacco mosaic virus (tobacco virus 1), J. A. PINCKARD and L. BOZOVANSKY. (Va. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 3, pp. 242–250, figs. 2).—Tobacco virus 1 remained infective in flue-cured tobacco leaves throughout four of the first five barns cured and in the lower and middle tiers of the fifth (1937). Although it was completely inactivated in the lower tiers of seven barns of cured tobacco, the final drying temperatures were higher than ordinarily required for curing. In other parts of the same barns, maximum temperatures were both above and below the thermal limit of the virus. Temperature differences amounting to as much as 50° F. were found within the same wood-fired barn. In five barns of tobacco cured with an oil-burning heating unit at no time was the thermal death point of the virus reached. Leaves infected with tobacco virus 1 lost weight and cure and became dry at the same temperature and time as did noninfected leaves. The temperatures required for a satisfactory "cure" varied, but were substantially below the thermal death point and time for complete inactivation.

Controlling damping-off of tomato seedlings with light, and chemicals on seed and soil, P. A. YOUNG. (Tex. Expt. Sta.). (*Amer. Jour. Bot.*, 25 (1938), No. 10, p. 18s).—An abstract.

The tipblight disease of tomato, F. P. McWHORTER and J. A. MILLERATH (*Oregon Sta. Circ.* 128 (1938), pp. 14, figs. 4).—The name "tipblight" is given to a virus disease typically developed in the tomato-canning counties of southern Oregon where yields have frequently been very seriously reduced. The results of the 4-yr. study here summarized include a description of the disease, its history and distribution, infectiousness, means of spread, and certain facts about the causal virus considered necessary for discussing control methods. Tipblight may be found in Rogue River Valley fields late in June, but it does not become abundant until July and August. The amount present and its dissemination are said to be directly influenced by the abundance of its insect

carriers (shown to be species of thrips) and the availability of the weed hosts of the carriers. The virus is said to be difficult to transmit by artificial inoculation, is unable to resist aging, high temperatures, or dilution in water, and is apparently not seed-borne. The possibility of weeds serving as virus reservoirs was experimentally demonstrated, though actual overwintering under field conditions has not yet been proved. Various indirect methods of control are outlined, and some progress is reported in the isolation and development of resistant strains of tomato.

Tomato tip-blight virus, J. A. MILLBRATH. (Oreg. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 2, pp. 156-168, figs. 4).—This virus is described as new, and some of its physical properties are described. The thermal death point lay at 40°-41.5° C., the "longevity" in vitro was less than an hour, and the dilution end point was less than 1-50. The virus was transmitted by *Thrips tabaci*, but mechanical transfer proved difficult. The symptoms of tipblight on various differential hosts are described, and methods of identifying the virus are discussed.

Tripsacum dactyloides, another native host of *Aplanobacter stewarti*, C. ELLIOTT and A. L. ROBERT. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 3, pp. 284, 285).—Lesions induced by *A. stewarti* (= *Phytophthora stewartii*) developed spontaneously on *T. dactyloides* at Arlington Experiment Farm, Va., grown from seed collected at Bellville, Tex., in 1936. The somatic cells contained the diploid number of 36 chromosomes characterizing the Texas form of this grass.

The 1938 wheat leaf-rust epiphytotic in Oklahoma, K. S. CHESTER. (Okla. Expt. Sta.). (U. S. Dept. Agr., Bur. Plant Indus., *Plant Disease Rptr.*, 1939, Sup. 112, pp. 18, figs. 2).—From the analysis here presented of the weather record, development of infection by *Puccinia rubigo-vera tritici*, varietal susceptibility, and other factors influencing the 1938 crop, "it is concluded that the leaf rust was the major reason for the 25 to 30 percent reduction in yield and quality of the 1938 wheat crop in Oklahoma. This conclusion is consistent with the findings of various cereal disease specialists who have studied the crop in the Southwest, and with the estimates of losses from leaf rust as the disease followed the crop northward from Texas to the Dakotas and Canada."

Boron deficiency as related to pimplly measles, internal cork, and similar apple diseases (New Jersey Stas. Plant Disease Notes, 16 (1938), No. 7, pp. 21-24).—A review of recent work in North America without references.

Stony pit, a transmissible disease of pears, J. R. KRENHOLZ. (U. S. D. A. and Oreg. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 3, pp. 260-267, figs. 2).—This is a preliminary report of studies begun in 1934 showing stony pit of pears to be due to a virus. Its symptoms consist of a fruit pitting, a so-called "oak-bark" effect, and probably a veinlet chlorosis of certain leaves. The trouble is known on the Bosc and occasionally on the Anjou varieties in California, Oregon, and Washington. It was transmitted to healthy Bosc and Anjou trees by budding from diseased Bosc trees, in most cases the symptoms appearing during the second season. Bartlett pears proved to be either tolerant or immune by the same method.

Brown-rot sclerotinias occurring in California and their distribution on stone fruits, W. B. HEWITT and L. D. LEACH. (Calif. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 4, pp. 337-351, figs. 4).—A discussion of earlier studies relative to the species causing brown rot of stone fruits in California is presented, showing that *Sclerotinia lara* has long been present and probably has been responsible for most of the brown rot therein described. *S. fructicola* may have been introduced relatively recently, causing the severe fruit rotting. Apothecia,

shown to be those of *S. fructicola*, were found in California on March 3, 1936, apparently for the first time, and have since been found in a number of peach orchards in the Sacramento Valley region. *S. lasa* was isolated subsequently from diseased apricot twigs, and the identity of each species was determined by comparisons in culture, spore measurements, pathogenicity studies, and by comparison with published descriptions. In a brown rot survey of the principal stone-fruit districts of California *S. lasa* was found throughout the districts from which specimens were obtained, whereas *S. fructicola* was more localized, occurring most abundantly in the Sacramento Valley. *S. fructicola* was isolated most frequently from brown-rot-diseased fruits, whereas *S. lasa* was isolated more frequently from blighted blossoms and twigs. In no instance was *S. fructicola* isolated from over-wintered blighted twigs of stone fruits that were producing sporodochia, all isolations from these twigs yielding *S. lasa*. The latter was the only organism isolated from brown-rot-affected flowers and twigs of almonds collected during this survey.

The "X" or "yellow-red virosis" disease of peaches (*New Jersey Stat. Plant Disease Notes*, 16 (1938), No. 9, pp. 30-33).—A descriptive review based on recent literature.

Virus diseases of the genus *Prunus* in Bulgaria, A. CHRISTOFF (*Phytopath. Ztschr.*, 11 (1938), No. 4, pp. 360-422, pls. 11).—This is a critical review of the literature (61 references), with a summary of the author's studies on virus diseases of stone fruits in Bulgaria.

Currant mosaic, E. M. HILDEBRAND. (Cornell Univ.). (*Phytopathology*, 29 (1939), No. 4, pp. 369-371, fig. 1).—This preliminary report describes a new virus characterized by chlorotic patterns on the leaves of red currants (*Ribes rubrum*) found in the Hudson River Valley. The more advanced stages are marked by stunting and by decline in vigor and fruitfulness, resulting in dieback and final death of diseased plants. Transmission was effected by grafting, but the suspected insect vector has not yet been found.

Diseases of strawberry, S. M. ZELLER (*Oregon Sta. Bul.* 357 (1938), pp. 23-30, figs. 7).—This is a brief presentation of important facts regarding diseases of this crop due to viruses (crinkle, yellows, and witches' broom), fungi (*Mycosphaerella fragariae* leaf spot, leaf scorch, leaf blight, mildew, *Armillaria* crown rot, and root and fruit rots), nematode gall, and alkali yellows.

Symptomatology of deficiencies and toxicities of citrus, A. F. CAMP. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 51 (1938), pp. 145-150).—This paper presents the leaf, fruit, and growth symptoms, distributions, and general discussions of zinc deficiency or freckling, copper deficiency or dieback and ammoniation (exanthema of Fawcett), magnesium deficiency or bronzing, manganese deficiency, and boron toxicity.

Limitations of the bark-scraping method in the control of gummosis and psorosis of citrus, A. S. RHOADS. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 51 (1938), pp. 114-127).—This is a further progress report on tests of this method begun in 1927 and recently reported (*E. S. R.*, 78, p. 69). Bark scraping is said to have proved effective in most cases for psorosis on orange trees and for both gummosis and psorosis on grapefruit trees, if done thoroughly and in the early stages. Aside from the basal form (foot rot), gummosis seems not to occur on orange trees in Florida but is widespread on both grapefruit and lemon trees, the latter being very susceptible and generally affected after attaining a few years of age. Psorosis is said to be much the more serious disease in Florida.

Spraying and pruning for melanose control, W. A. KUNTZ and G. D. RUMBLE. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 51 (1938), pp. 89-

102).—As a result of a 4-yr. study of melanose control by spraying with copper fungicides and by pruning, it is concluded that as a disease of commercial citrus varieties under Florida conditions melanose cannot be entirely eliminated since the causal *Phomopsis* is always present and produces varying damage from season to season. Although cold injury, "cropping strain," and severe scale infestations have not been thoroughly studied, these three strongly modifying factors should be avoided as far as possible to assist in better melanose control. Since they are largely responsible for dead wood in the trees, there are times and seasons when pruning is essential for the regaining of normal vigor and to aid in lessening the abundance of the melanose fungus. With bright fruit the sole objective, spraying should be emphasized, but it is believed that combined pruning and spraying will produce the best results from the standpoints of both the trees and the production of bright fruit.

Pitting and decay in pineapple oranges, [C. O. BRATLEY] and J. R. WINSTON. (U. S. D. A.). (*Citrus Indus.*, 20 (1939), No. 1, pp. 6, 7, 17, 20, 21, figs. 4).—Preliminary results of tests to determine the effects of various packing house practices and of different transit temperatures on the condition of fruit on arrival at the market seem to indicate that the beneficial effects of low transit temperatures on control of decay lasts throughout a marketing period of one week, but even so the loss, particularly from blue mold (*Penicillium*) rot, in all lots was excessive. Fruits from each of the five cooperating Florida growers were considerably pitted on arrival at New York, and after 7 days were severely pitted. In these tests it was clear that the amount of pitting was greatly increased by packing house operations and particularly by the "color added" treatment, and it is deemed imperative that each step in handling the fruit be examined so that injury may be kept at a minimum.

Control of black rot of pineapples in transit, C. O. BRATLEY and A. S. MASON (U. S. Dept. Agr. Circ. 511 (1939), pp. 12, fig. 1).—In 14 holding tests in Puerto Rico and 7 shipping trials between Puerto Rico and New York City, alcoholic solutions of benzoic acid proved the most effective of several materials tried for controlling *Thielaviopsis paradoxa* infection of Red Spanish pineapples applied to the cut surface of the stem within 2 hr. after harvesting—and without acid in 100 cc. of 30-percent alcohol gave as good control as higher strengths when applied to the cut surface of the stem within 2 hr. after harvesting—and without injury to the fruit. About one-fifth of the decay started at packing bruises on the side of the fruit. The correct diameter and weight of fruits for each packing size were determined and are listed, and it was found that proper sizing prevented much of the bruising.

Geographical distribution of yellow spot of pineapples, W. CARTER. (Hawaii. Pineapple Producers' Expt. Sta.). (*Phytopathology*, 29 (1939), No. 3, pp. 285-287, fig. 1).—The author reports the finding of typical yellow spot of pineapples in the Bathurst area of South Africa. The fruit symptoms were most common, suggesting the vector of this virus in that area to be primarily a flower feeder, possibly *Frankliniella schultzei*. No yellow spot was found on the Island of Mindanao, P. I., either in pineapples or *Emilia*, although the latter plant was generally distributed.

Delphinium diseases, P. P. PIRONE. (Cornell Univ.) (*Delphinium* [Amer. Delphinium Soc.], 1937, pp. 49-51, figs. 3).—Brief notes on crown rot (*Sclerotium delphini*), mildew (*Erysiphe polygoni*), and leaf spot (*Phytophthora delphinii*), including control measures.

Powdery mildew of Delphinium, E. B. MAINS (*Delphinium* [Amer. Delphinium Soc.], 1937, pp. 51-53, figs. 2).—A brief note on this disease, including the results of inoculation tests on *Delphinium* spp. and other hosts as suggesting

the fungus to be limited to the former genus and to be present in more than one race. Resistant strains of the host are considered to be the best means of control.

A new menace to gardenias—bacterial leaf spot, P. P. PIRONE. (N. J. Expt. Stas.). (*Florists' Ench. and Hort. Trade World*, 92 (1939), No. 6, p. 18, fig. 1).—Preliminary results here briefly noted indicate the new leaf spot to be bacterial in origin and to present a serious menace to the growing of gardenias under glass.

Two mosaic diseases of annual stock, C. M. TOMPKINS. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 1, pp. 63-77, figs. 7).—Virus-induced mild mosaic and severe mosaic of *Matthiola incana* are described. These diseases prevail in the cool coastal valleys of California and cause considerable loss in the cut-flower and seed crops. Leaf mottling and flower breaking are the principal symptoms of both but are more conspicuous in the severe form. These viruses were readily transmissible by carborundum inoculations with juice. Spontaneous transmission is by the turnip or false cabbage aphid (*Lipaphis pseudobrassicae*), which breeds on annual stock. Seed transmission tests were negative. All self-colored varieties proved highly susceptible, but only the mottling symptom occurred on white- and yellow-flowered varieties. Hosts susceptible to both forms of virus include turnip, black mustard, white mustard, dames violet, evening scented stock, charlock, shepherds-purse, mignonette, and Turkish and White Burley tobaccos. Failure to infect cabbage, cauliflower, kale, brussels sprouts, sprouting broccoli, kohlrabi, rape, and rutabaga serves to differentiate these two annual stock mosaic viruses from certain other crucifer viruses, while differential hosts are also one means of differentiating the two mosaics themselves. Susceptible to infection with the mild mosaic virus only are Chinese or leaf mustard, pe-tsai, radish, Chinese radish, Virginia stock, honesty, sweet alyssum, wallflower, *Brassica adpressa*, sowbane or nettle-leaf goosefoot, *Nicotiana glutinosa*, and *N. langsdorffii*. Infection of lambsquarters, spinach, and petunia was obtained only with the severe mosaic virus. Studies on the properties of these viruses indicated the mild mosaic form to remain infectious for five days after storage at 22° C. and the severe form for seven days. Both were inactivated at 58°-60°. The mild mosaic virus infected up to 1:4,000 and the severe mosaic virus up to 1:3,000 dilution. Flower breaking of annual stock may also be induced by the mosaic viruses of Chinese cabbage, turnip, horseradish, and cabbage and also by the cabbage black-ring virus.

Bordeaux injury on walnut quality, B. A. RUDOLPH. (Calif. Expt. Sta.). (*Pacific Rural Press*, 137 (1939), No. 8, p. 182).—This is a general account including local observations.

Avenues of entrance for canker-forming Nectrias of New England hardwoods, T. J. GRANT and P. SPAULDING. (U. S. D. A. et al.). (*Phytopathology*, 29 (1939), No. 4, pp. 351-358, fig. 1).—From observations and measurements of more than 3,000 *Nectria* cankers on various hardwood species (birch, maple, aspen, oak, hickory, and pin cherry) in several New England forests, together with two series of inoculations close to the axils of branches, it was indicated that branches on hardwoods and especially the small young branches, buds, and short spurs on birches often serve as avenues of entry for the canker fungus. However, branches over 0.5 in. in diameter do not serve as avenues of entrance for Nectrias into larger branches or trunks unless infection occurs at or very close to their axils. Inoculations and field observations indicated that infection usually occurs through living or dying branches rather than through completely dead branch stubs. The size of the branch attacked, the time of year that injury occurs, and the host reactions are

important factors in canker development. In general, small stems were more readily girdled than large ones, and fall and winter injuries appeared to be more important than those occurring in late spring or early summer, when prompt activity of the cork cambium may aid in checking early stages of invasion by the fungus.

The canker of *Cupressus* induced by *Coryneum cardinale* n. sp., W. W. WAGENER. (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 1, pp. 1-46, figs. 10).—This disease—characterized by resinous lesions in the bark of twigs, branches, and trunks, resulting in ultimate girdling—was discovered in California in 1927 (E. S. R., 59, p. 646) and has since become one of the important tree diseases of the region. The principal hosts are *Cupressus macrocarpa* and *C. sempervirens stricta*, but isolated infections have been found on *C. pygmaea*, *C. forbesii*, *C. lusitanica*, *Thuja orientalis*, *Chamaecyparis lawsoniana*, *Libocedrus decurrens*, *Juniperus chinensis femina*, and *J. sabina tamariscifolia* (?). In California the disease is epidemic on planted cypresses, with an estimated loss to date of 30,000 trees, but it has not yet been found in the restricted native groves of *Cupressus*. It has also been reported from New Zealand. Trees of any size or age may be attacked by it.

Coryneum cardinale n. sp. is fully described and shown to be the cause. An unnamed saprophytic *Coryneum* with nearly identical spores also occurs on *Cupressus macrocarpa*, and the two are differentiated. Exposure of the parasitic species to low temperatures slightly depressed subsequent growth at favorable temperatures. Extension of the cankers in length averaged ± 20 cm. per year at an inland station and ± 10 cm. at a cool, coastal station. Spore production in nature is governed chiefly by humidity. In dry storage spores remained viable as long as 42 mo. Dissemination is said to be chiefly by natural means, but also to occur through infected plant materials and locally on pruning tools. Coated slides and plates exposed to wind yielded but few spores, but as high as 228 per square centimeter were caught on filter paper under cankers during rains. In the field infection may evidently occur with or without wounds, but experimental infections without wounding were inconclusive. Inoculations demonstrated susceptibility to be pronounced for *C. macrocarpa*, moderately high for *C. sempervirens indica* and *J. virginiana*, medium for *C. lusitanica*, *C. arizonica*, and *C. macnabiana*, and slight or absent for *T. occidentalis*, *J. occidentalis*, *Cryptomeria japonica*, and *L. decurrens*. The disease was probably established in California as early as 1915, but proof of its origin is lacking. The importance of preventing establishment of the fungus in new districts is stressed. A bibliography of 44 titles is included.

The cause of pecky cypress, W. A. MURRILL. (Fla. Expt. Sta.). (*Bul. Torrey Bot. Club.*, 66 (1939), No. 2, pp. 87-92, figs. 6).—"Pecky cypress," now used for antiques and interior finishing, is said to be due to *Fomes geotropus*. The occurrence of the fungus fruiting brackets appears to be rare, and a case of such development on an affected specimen of common baldcypress (*Taxodium distichum*) is described and fully illustrated. The fungus was found on boxelder and magnolia, and herbarium specimens of infected sweet gum, linden, red bay, and winged elm are also noted.

"Cephalosporium die-back" of elms, F. A. MCCORMICK. (Conn. [New Haven] Expt. Sta.). (*Phytopathology*, 29 (1939), No. 4, pp. 371, 372).—Two elm trees (New Haven, Conn.) are reported to have been infected with *Dothiorella ulmi* (*Cephalosporium* sp.) and under observation for 11 yr. During this time repeated cultures have produced the same fungus, although the trees are said to be in fully as good condition as when infection with this supposedly virulent

fungus form was first noted. Observations and inoculations suggest the probability that the particular fungus strain involved is low in virulence.

Damping off as a factor in the natural distribution of pine species, S. A. WILDE and D. P. WHITE. (Univ. Wis.). (*Phytopathology*, 29 (1939), No. 4, pp. 367-369, fig. 1).—Coinciding closely with present empirical knowledge of the relative resistance of pines to damping-off, greenhouse tests with samples of representative soils from the arboretum area (near Madison, Wis.) resulted in almost complete loss of red pine (*Pinus resinosa*) seedlings on heavy mull soils, less damage to white pine (*P. strobus*), and no infection on Austrian pine (*P. nigra*). These results suggest that a prominent role is played by the damping-off fungi prevalent on these soils of calcareous origin in limiting the distribution of certain pines. In the light of these findings the advisability of extensive plantings of northern conifers on heavy calcareous soils is questioned.

The probable mechanism of the protective action of resin in fire wounds on red pine, A. F. VERRALL (*Jour. Forestry*, 36 (1938), No. 12, pp. 1231-1233, fig. 1).—Fire wounds are generally considered as common foci for the entrance of wood-destroying fungi. In Minnesota a large majority of mature red pines (*Pinus resinosa*) were found to be entirely free of decay behind fire wounds, even when the latter included 25 percent of the circumference of the tree and had been present for over 50 yr. This relative lack of decay is believed to be due to the infiltration of resinous materials into the exposed wood. While essentially nontoxic, this infiltrate acts as a waterproofing layer, preventing the penetration of wood-destroying organisms.

Breeding horticultural crops for resistance to the root-knot nematode, K. C. BARRONS. (Ala. Expt. Sta.). (*Assoc. South. Agr. Workers Proc.*, 39 (1938), pp. 106, 107).—An abstract.

ECONOMIC ZOOLOGY—ENTOMOLOGY

[Work in zoology and entomology by the Alabama Station] (*Alabama Sta. Rpt. 1937*, pp. 31-34).—The work of the year briefly referred to (E. S. R., 78, p. 815) includes the vegetable weevil, by J. M. Robinson; life history and control of the cowpea curculio, by F. S. Arant; the control of citrus insects with oil emulsions, the toxicity of derris to white fly larvae and purple scale, and the effect of oils on satsuma trees, all by L. L. English; and fertilizers and plants for farm ponds, by H. S. Swingle, E. V. Smith, and G. D. Scarseth.

[Work in economic zoology and entomology by the Iowa Station]. (Partly coop. U. S. D. A.). (*Iowa Sta. Rpt. 1938*, pts. 1, pp. 134-144, 145; 2, pp. 59-61).—The work of the year in this field is briefly reported (E. S. R., 79, p. 503). Part 1 takes up the influence of meteorological factors upon honey production and factors involved in the transformation of nectar into honey by the honeybee, both by O. W. Parks; the wheat insect pest survey, biology and control of onion insects (the onion mirid *Labopidea alli* Knight, and the black onion fly *Tritoma flexa* Weid.), and survey of potato insects, all by C. J. Drake; insecticides and insect toxicology, particularly as relate to the lesser migratory grasshopper *Melanoplus mexicanus mexicanus* Sauss., and the bio-nomics and control of the codling moth and other apple insects, both by C. H. Richardson; emergency grasshopper investigations, by Drake and Richardson; environmental carrying capacity for wintering bobwhite quail and the ecology of the muskrat, both by P. L. Errington; variation in resistance to American foulbrood in honeybees and supersedure of queens by honeybee colonies, both by Park and F. B. Paddock; the ecology and management of the raccoon (*Procyon*

lotor), by L. J. Bennett and G. O. Hendrickson; and studies with cottontail rabbit (*Sylvilagus floridanus mearnsi*), by Hendrickson.

Part 2 reports on white grub (*Phyllophaga* spp.) investigations, by Drake and E. V. Collins; the bionomics and control of the chinch bug, by Drake, Richardson, and G. C. Decker; and the nutrition and metabolism of insects (largely insects attacking stored grain and foods), by Richardson.

[Work in economic zoology and entomology by the Cornell Station] ([New York] Cornell Sta. Rpt. 1938, pp. 89, 111-115, 115-118).—The work of the year referred to (E. S. R., 79, p. 71) included the nutritional requirements of trout, by C. M. McCay and A. V. Tunison; ecological and life history studies on the alfalfa snout beetle, by C. E. Palm, C. G. Lincoln, and W. D. Wylie; white grub and other forage crop insects, by Palm, T. W. Kerr, Jr., and C. P. Zorsch; biology and control of the two common clothes moths and dermestid larvae injurious in dwelling houses, both by G. H. Griswold; wireworms (wheat wireworm and eastern field wireworm) and their injuries to potatoes, by G. F. MacLeod and W. A. Rawlins; the efficiency of spraying and dusting practices in protecting potatoes grown on muck soils, by MacLeod and H. Menusan, Jr.; insects attacking potatoes on Long Island, by MacLeod and J. O. Nottingham; biology and control of onion thrips, by MacLeod and W. H. Ewart; nonpoisonous sprays, by T. R. Hansberry and L. B. Norton; honey, with special reference to the origin of special ingredients, by E. F. Phillips, E. C. Martin, and W. L. Coggeshall; and propagation of natural fish forage and bait and a study of body proportions of trout, both by G. C. Embody.

[Work in economic zoology and entomology by the Texas Station]. (Partly coop. U. S. D. A.). (Texas Sta. Rpt. 1937, pp. 57-67, 144-151, 156-159, 175, 176, 206, 207, 256, 265, 271-273, 281, 303, 304).—The work of the year reported upon (E. S. R., 79, p. 76) relates to the biology, control and taxonomy of white grubs (*Phyllophaga* spp.) in Texas, by H. J. Reinhard; bollweevil, its control and hibernation, by J. C. Gaines, Reinhard, M. J. James, W. L. Owen, Jr., and R. W. Moreland; cotton flea hopper, its migration or dispersal, abundance, control, and hibernation, by F. L. Thomas, Gaines, K. P. Ewing, Owen, and Reinhard; the flower thrips, by Thomas and Gaines; the pink bollworm, including parasite studies, varietal resistance, cultural control, and remedial measures, by A. J. Chapman; the cotton bollworm, its hibernation and spring emergence and biology, by R. K. Fletcher; sulfur as an insecticide, by S. E. Jones, Thomas, and W. S. McGregor; pecan insect investigations, by S. W. Bilsing; devil's shoestring (*Tephrosia virginiana*) as an insecticide, by V. A. Little, G. A. Russell, and Thomas; southwestern corn borer, by Thomas and McGregor; truck crop insect (Hawaiian beet webworm, corn earworm, turnip aphid, common red spider, northern mole cricket, and southern mole cricket) investigations, by J. N. Roney; apiary inspection, 1936-37, by C. E. Heard and C. J. Burgin; activities of bees and relationship of honey plants to insects, both by H. B. Parks; adaptability of native honey plants (E. S. R., 78, p. 598), queen rearing, breeding for resistance to American foulbrood, and bee production, all by Parks and A. H. Alex; horsemint for honey and oil production, by Parks and V. L. Cory; Walker County, Tex., wildlife resources survey, by D. W. Lay and W. P. Taylor; field studies of bobwhite quail in east Texas, by V. Lehmann, D. H. Reid, H. Hahn, and H. R. Siegler; plant-wildlife relationships, by S. R. Warner and Lay; the gray squirrels and fox squirrels of east Texas, by P. D. Goodrum; ecology of the Attwater prairie chicken, by Lehmann; present status and future needs of vanishing species, by Taylor; at the Tyler Substation insect investigations with thrips, the bollworm, and the peach tree borer, by Owen; at the Temple Substation miscellaneous insect pests, by

C. H. Rogers; at the Chillicothe Substation control of the cotton flea hopper; at the Sonora Substation a study of screwworm and fly repellents, by W. H. Dameron, and insects affecting animals, including goat lice, sheep fly, sheep botfly, and winter tick, the effect of first-instar larvae on the eye of sheep, wetting agents, and larvicides, by O. G. Babcock; at the Weslaco Substation entomological experiments with the citrus mite, pea aphid, tomato fruitworm, scale on citrus, and cottony cushion scale; and at the Winter Haven Substation investigations with the beet leafhopper, corn earworm, cabbageworms (the diamondback moth and cabbage looper), onion thrips, and *Paratrioza cockerelli* (Sulc.), by Janes, and with the California red scale *Aonidiella aurantii* (Mask.), *Anychus clarki* McG., the seed-corn maggot, the blister beetle *Macrobasis albida* (Say), and the spotted cucumber beetle, by E. Mortensen.

Problems of animal ecology, F. S. BODENHEIMER (*Oxford: Univ. Press*, 1938, pp. VI+[1]+183, figs. 28).—This subject is dealt with in connection with a 7-page list of references to the scientific literature of the world.

[Conservation of wildlife] (*Internat. Assoc. Game, Fish, and Conserv. Commrs. Convs., Proc.*, 29 (1935), pp. 102, figs. 3; 30 (1936), pp. 114, fig. 1; 31 (1937), pp. 68, figs. 4).—The proceedings of the conventions of the International Association of Game, Fish, and Conservation Commissioners held in 1935, 1936, and 1937, are presented. A contribution on Research and Game-Management Units in Land Grant Colleges, by W. C. Henderson, is included in the report for 1935 (pp. 87-90).

[Work in game management by the Wisconsin Station] (*Wisconsin Sta. Bul.* 442 (1938), pp. 48-51, fig. 1).—The work of the year referred to (E. S. R., 78, p. 813) relates to quail management, by A. Gastrow and A. Leopold; the nesting of birds in hayfields, by Leopold and A. S. Hawkins; and the type of pheasant that survives the best, by I. O. Buss and Leopold.

A history of Nebraska ornithology, M. H. SWENK (*Nebr. Bird Rev.*, 1 (1933), No. 2, pp. 50-53; 2 (1934), No. 4, pp. 137-143; 3 (1935), Nos. 2, pp. 69-74; 3, pp. 115-125, fig. 1; 5 (1937), No. 3, pp. 51-57).—The several parts of this contribution, each of which is accompanied by a bibliography, deal with the subject as follows: (1) The ancient period (pp. 50-53, 137-143), (2) period of the earliest explorations (pp. 69-74), and (3) period of the explorations of the early nineteenth century (1804-1854) (pp. 115-125, 51-57).

The birds of El Salvador, D. R. DICKEY and A. J. VAN ROSSEM (*Field Mus. Nat. Hist. [Chicago] Pub., Zool. Ser.*, 23 (1938), pp. 609, pls. 24, figs. 29).—This contribution is based upon several years' field work in the collection of birds in El Salvador. It is presented with an account of each form, including locality of collection, status of occurrence, plumage notes, and other information such as nesting habits, etc., and, in some cases, stomach contents.

Notes on the insect-food of the little owl, A. HIBBERT-WARE (*Roy. Ent. Soc. London, Proc., Ser. A*, 12 (1937), No. 4-6, p. 68).—The notes here presented relate particularly to the European earwig as food of the little owl and a list of Coleoptera identified in the pellets and other food material.

[Work in entomology by the Maine Station] (*Maine Sta. Bul.* 391 (1938), pp. 234-238, 241-243, 256, 257, 304, 305, 311-313, figs. 2).—Included in the work referred to (E. S. R., 79, p. 76) are investigations with pea aphids, their life history, factors which cause their abundance and the relation of fungus disease to such abundance, insect parasites and predators, losses caused, and tests with insecticides, spreaders, and machinery for their control, by J. H. Hawkins; insects affecting the apple crop, particularly the gypsy moth, the apple maggot, the plum curculio, and the apple seed chalcid, by F. H. Lathrop; the Mexican bean beetle and wireworms affecting the potato crop (including the re-

lation of cultural practices to wireworm control and crop rotations for their control), both by Hawkins; and blueberry insects, particularly the blueberry maggot and the blueberry thrips *Frankliniella vaccinii* Morg., by Lathrop.

[Work in entomology by the Oklahoma Station] (*Oklahoma Sta. [Bien.] Rpt. 1937-38*, pp. 62, 63, 75-97, 100, figs. 6).—Following reference to the occurrence of the important insects of the biennium (*E. S. R.*, 77, p. 66) brief reports are made of the absence of ill effects from grazing lambs under sprayed and dusted pecan trees; poison bait and fungus disease control of grasshoppers, by B. R. Walton, F. E. Whitehead, L. G. Duck, and W. W. Ray; the extermination of red harvester ants by the proper use of either carbon bisulfide or calcium cyanogas, by R. G. Dahms; the chinch bug problem, including winter surveys, the finding of a beetle (*Collops quadrimaculatus* F.) to be a very important enemy, and tests to determine the relation of nitrogen and phosphorus fertilizers to chinch bug resistance in sorghums (coop. U. S. D. A.), by Dahms and M. Kagan; control of the wheat white grub by crop rotation, by F. A. Fenton and C. B. Cross; the overwinter survival of the corn earworm, control of the walnut caterpillar on pecans by pruning, spraying, or dusting, the use of high-yielding varieties of cotton in combating the bollweevil, and control of the red-necked cane borer by pruning and by planting resistant varieties, all by E. Hixson; armyworm control by the use of baits and control of the European fruit lecanium with oil spray, both by Fenton; control of housefly nuisance by the chemical treatment of manure, by Fenton and Stricklen; control of the flat-headed apple tree borer by pruning and tree wraps, by Fenton, Johnson, and Bewick; the resistance of bollweevils to relatively low temperatures, by Hixson and C. A. Sooter; a study of the effect of terracing and pond-making on the mosquito problem, by L. E. Rozeboom; and a study (1) in an experimental apiary of the period and rate of nectar flow, (2) of the effectiveness of hexachloroethane against the corn earworm (coop. U. S. D. A.), and (3) of control of the egg-plant lace bug by a mixture of superfine dusting sulfur containing 2 percent rotenone, all by G. A. Bieberdorf.

[Research work in economic entomology by the Oregon Station] (*Oregon Sta. Circ. 130 (1938)*, pp. 5, 10, 11, 15, 18, 21-26, 34, 35, 39, 44, 45, 46, figs. 40).—Brief accounts are given in this preliminary report as follows: Problems of fur farming in Oregon; nursery insects; rotation control of the flax worm, officially known as the strawberry fruitworm, and other flax pests; the onion maggot; insect pests of hops; control of the filbert moth and other filbert pests, the pea weevil and the pea aphid, and the potato flea beetle; chemical control work with the symphylid enemy of vegetable and flower gardens; and prune thrips control.

[Work in economic zoology and entomology by the Pennsylvania Station] (*Pennsylvania Sta. Bul. 367 (1938)*, pp. 57-60, fig. 1).—The work of the year reported upon (*E. S. R.*, 78, p. 511) relates to the timing of sprays for control of the codling moth, by D. E. H. Frear and H. N. Worthley; control of red mite, by Worthley; tomato pinworm, the greenhouse symphylid, wireworms, and mushroom pests, all by C. A. Thomas; the rose leaf beetle, by M. Wood; sod webworms, by H. C. Hallock; and trout food in a Centre County stream, by G. L. Trembley.

[Work in economic entomology by the South Carolina Station] (*South Carolina Sta. Rpt. 1938*, pp. 63-73, 114-125, 136-144, 189-194, figs. 13).—The work of the year briefly reported (*E. S. R.*, 79, p. 360) relates to the tomato fruitworm and a faunal survey, both by F. Sherman; the rice weevil in corn and the oriental fruit moth, both by O. L. Cartwright; corn earworm studies, by Cartwright and J. N. Todd; the Mexican bean beetle and the cowpea curculio, both by Sherman and Todd; and at the Pee Dee Substation bollweevil

and miscellaneous cotton insect investigations, including the testing of substitutes for calcium arsenate, tests of presquare treatments for bollweevil control, randomized plat arrangement for testing calcium arsenate with low, medium, and high water-soluble arsenic content, spring and fall examinations of Spanish moss in 1937-38, and examination of woods trash for hibernating bollweevils, experiments in the hibernation of bollweevils in cages, cotton trap crop for bollweevil emergence, and experiments in control of the cotton root aphid and cotton leaf aphids, by F. F. Bondy and C. F. Rainwater, and experiments with insecticides as a control for the tomato worm and the tobacco flea beetle on tobacco, by N. Allen, J. W. Humphreys, and D. B. Lieux.

Work at the Edisto Substation mentioned includes insect control studies, particularly with the asparagus beetle, bollweevil, and the corn budworm, by J. G. Watts.

[Contributions on economic insects and insecticides] (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 25 (1937), pp. 203-228, pls. 2, fig. 1).—The following contributions (E. S. R., 79, p. 217) are presented: Notes on Some Interesting Insects Observed on Fruit Trees in 1937, by A. M. Massee (pp. 203-208); Notes on the Strawberry Aphid (*Capitophorus fragariae* Theob.) (pp. 209-212) and Studies of Impregnated Tree Banding Materials—IV, Apple Blossom Weevil [*Anthonomus pomorum* (L.) Curt.] and Codling Moth Experiments in 1937 (pp. 213-218), both by A. M. Massee, R. M. Greenslade, and A. J. Duarte; Spray Residue Investigations—II, The Influence of Spray Supplements on the Retention of Lead Arsenate on Apples, by H. Shaw and W. Steer (pp. 219-222); and Experiments in the Control of Plum Sawfly [*Hoplocampa flava* L.] on Czar Plums, by W. Steer and A. A. G. Hassan (pp. 223-228).

[Contributions on economic insects and mites] (*Jour. Southeast. Agr. Col., Wye, Kent, No. 42* (1938), pp. 60-63, 66-92, 214, 215, figs. 13).—The several contributions presented are: Tests of Ovicidal Washes Against *Tetranychus telarius* L. on Hops, by S. G. Jary and M. D. Austin (pp. 60-63); Investigations on the Insect and Allied Pests of Cultivated Mushrooms—XII, Two More Tyroglyphid Mites [*Caloglyphus* sp. ? *berlessei* and *Eberhardia* sp.], by S. G. Jary (pp. 66-81) (E. S. R., 77, p. 815); The Control of Big Bud Mite (*Eriophyes ribis* (Westw.) Nal.), by Lime Sulphur, by S. G. Jary, M. D. Austin, and R. S. Pitcher (pp. 82-92); and Notes on Diplopoda—V, The Recognition of Some Millipedes of Economic Importance, II, by S. W. Rolfe (pp. 214, 215) (E. S. R., 77, p. 815).

Insect and other pests of 1937, A. E. CAMERON (*Highland and Agr. Soc. Scot. Trans.*, 5. ser., 50 (1938), pp. 94-127, figs. 18).—A summary of information on pests of importance in Scotland in 1937 (E. S. R., 78, p. 815).

Insect pest work (*Empire Cotton Growing Corp., Egypt. Stas. Prog. Rpts.*, 1936-37, pp. 26-41, fig. 1).—In part 1 of this contribution from the Barberton Experiment Station, Union of South Africa (E. S. R., 79, p. 218) F. S. Parsons, H. Hutchinson, and J. Marshall report on investigations on the American and red bollworms (pp. 26-32) and in part 2 E. O. Pearson reports on investigations on cotton stainers and internal boll disease (pp. 33-41).

Entomological notes (*Agr. Jour. [Fiji]*, 9 (1938), No. 4, pp. 12-19, pl. 1, fig. 1).—Accounts of a Javan parasite (*Pleurotropis* sp.) of the coconut leaf miner *Promecotheca nuciferae* Mik., introduced into New Guinea from Fiji, by R. J. A. W. Lever (pp. 12-14); local fruitflies and their parasites (pp. 14, 15); introduction of the beetle *Hister chinensis* Guen., from Hawaii for the control of houseflies (pp. 15, 18); local insect pests of books and their control (p. 18); and use of sodium silicofluoride as an insecticide (p. 19) are noted.

Insect collections of the world, I-III [trans. title], W. HOEN and I. KAHLE (*Ent. Beihefte Berlin-Dahlem*, 2 (1935), pp. 160-112, pls. 16; 3 (1936), pp. 161-

296, pls. 10; 4 (1937), pp. 297-536+VI, pls. 12, figs. 2).—The first and main part of this work takes up the nature and location of these collections (pp. 1-388). The arrangement is in alphabetical order under the names of the entomologists, past and present, who have assembled collections of insects of any extent, together with the location of the collections. Additional data are presented in the seven supplementary parts (pp. 389-510).

Dispersal of insects by air currents, E. P. FELT (*N. Y. State Mus. Bul.* 274 (1928), pp. 59-129).—The information presented, based upon a review of the literature and investigations conducted, reveals the fact that winds, especially those of the upper air, are sufficient for the occasional and possibly somewhat general extended movements of insects. There appears to be no indications that such movements are limited to species possessing superior flying ability, since the probabilities are that the purposive flight of an insect, that is, the distance covered by its own efforts, is relatively insignificant. A four-page list of references to the literature is included.

Wind drift and dissemination of insects, E. P. FELT (*Canad. Ent.*, 70 (1938), No. 11, pp. 221-224).—Data obtained subsequent to that above noted have tended to confirm rather than weaken the conclusions incident to that study.

Plant breeding and cotton insect pests, F. R. PARNELL (In *Third Conference on Cotton Growing Problems, September 1938—Report and Summary of Proceedings*. London: Empire Cotton Growing Corp., 1938, pp. 81-85).—A practical discussion.

A note on a new method of control for insect pests of the cotton plant, T. G. MASON and E. PHILLIS (*Empire Cotton Growing Rev.*, 14 (1937), No. 4, pp. 308, 309).—A discussion of the relative toxicity of selenium to plants and animals and its possible use as an insecticide.

A preliminary annotated list of fruit pests of the North-West Frontier Province, H. S. PRUTHI and H. N. BATRA (*Imp. Council Agr. Res. [India], Misc. Bul.* 19 (1938), pp. 18).—Information is given on some 40 insect pests of fruit and melons under observation in the North-West Frontier Province.

An annotated conspectus of the insects affecting fruit crops in S. India, T. V. RAMAKRISHNA AYYAR (*Madras Agr. Jour.*, 26 (1938), No. 9, pp. 341-351).—An annotated conspectus of all the fruit insects so far noted in south India, with brief notes on their economic and bionomic importance and some general suggestions for control.

Two new winter washes for fruit trees, G. L. HEX (*Jour. Min. Agr. [Gt. Brit.]*, 45 (1938), No. 9, pp. 932-940).—In the experiments of 1937 and 1938 reported, (1) a synthetic organic thiocyanate wash consisting of β -butoxy- β' -thiocyanodiethylether and (2) 3 to 5 parts of dinitro-*o*-cresol, both incorporated in petroleum oil, were tested on fruit trees. The former gave a good control of the apple aphid, apple capsid, and the woolly apple aphid when applied to apples in the green tip and delayed dormant stage. It also reduced the caterpillar infestation without causing damage to the trees. The dinitro-*o*-cresol wash at 7 percent proved an efficient aphid ovicide at five centers, slightly superior to the thiocyanate-oil wash, and in no way inferior to a tar oil wash. At one center it proved slightly inferior to the thiocyanate-oil wash and at another it gave highly variable results against aphid.

Apple insect control studies in 1938 (progress report), H. N. WORTHLEY and H. M. STEINER (*Pennsylvania Sta. Bul.* 376 (1939), pp. [2]+13, figs. 2).—The results of spraying experiments in 1938 for the control of the European red mite, rosy apple aphid, codling moth, and pistol casebearer are presented and discussed, the details being given in six tables. While good aphid control was

obtained with tar oil and certain other toxicants added to dormant petroleum oil sprays, and with nicotine sulfate added to delayed dormant sprays of liquid lime-sulfur or petroleum oil, none of the spray mixtures tested proved satisfactory against winter eggs of European red mite.

In moderate infestations in south-central Pennsylvania orchards where most of the damage in 1938 was caused by second-brood codling moth larvae, lead arsenate continued to give the best control but not without producing harvest residues of lead in excess of the present tolerance of 0.025 gr. per pound. Under these conditions the addition of stickers to lead arsenate in four cover sprays failed to show increased control. A high degree of codling moth control and lessened spray injury was obtained by producing a heavy lead arsenate deposit in the second, the final, cover spray through the employment of an inverted or "dynamite" spray mixture. The omission of lime-sulfur from the cover spray mixture of lead arsenate and lime resulted in a great increase in arsenic injury to the foliage, while the substitution of a so-called insoluble copper (copper phosphate) fungicide for the lime-sulfur seriously interfered with codling moth control.

Preliminary tests of sprays for pistol casebearer control suggest that, while an increase in populations of this insect may be retarded or prevented through the use of lead arsenate in a full schedule of foliage sprays applied with thoroughness, this treatment will not serve to reduce an outbreak. For this purpose best results were secured with two sprays containing 0.75 percent summer oil and nicotine sulfate at the rate of 1 pt. per 100 gal. applied in early July against the eggs and young larvae. These sprays were applied with great care to wet both under and upper sides of the leaves, especially those in the top center of the trees.

Insect pests of strawberry, W. D. EDWARDS and S. M. ZELLER (*Oregon Sta. Bul.* 357 (1938), pp. 5-23, figs. 12).—A practical account of the insect and mite enemies of strawberry in Oregon and means for their control. Those of major importance are spittle bugs, strawberry root weevils (*E. S. R.*, 75, p. 525), the strawberry fruitworm, the strawberry leaf roller and the western strawberry leaf roller *Anacampsis fragariella* Busck., the cyclamen mite, the strawberry crown moth *Synanthedon bibionipennis* Boisd., the strawberry crown miner *Aristotelia fragariae* Busck., and the strawberry aphid.

Insects infesting stored grain and seeds, H. H. SHEPARD (*Minnesota Sta. Bul.* 340 (1939), pp. 30, figs. 11).—In this bulletin, which replaces Bulletin 198 (*E. S. R.*, 47, p. 453), the subject matter has been largely rewritten and brought up to date where necessary.

A list of granary insects and their associates from Japanese Empire [trans. title], S. NAKAYAMA (*Chosen Govt. Gen. Agr. Expt. Sta. Ann.*, 10 (1938), No. 2, pp. 153-170, pls. 3; *Eng. abs.*, pp. 166-168).—A list is given of 64 species of insects and mites and their predators and parasites found in warehouses, etc., in Japan. Of these, 10 species are of primary importance as stored grain pests.

The enemies of hazelnut, chestnut, and pistachio nut trees, P. T. ANAGNOSTOPOULOS (*Dendrok. Ereuna (Hort. Res.)*, 3 (1938), No. 3, pp. 497-544, figs. 28).—The more important pests of these nut trees in Greece are dealt with in this article, of which all except the title is in the Greek language.

A guide to the insects of Dalbergia sissoo for forest officers, C. F. C. BEESON ET AL. (*Indian Forest Rec.*, n. ser., *Ent.*, 4 (1938), No. 1, pp. [31]-42, figs. 2).—This guide deals with insects attacking the living tree (pp. 7-23) and insects attacking the felled tree and timber (pp. 24-35), the arrangement being systematic according to the parts attacked.

A survey of the insect pests of eucalypts in New Zealand, A. F. CLARK (*New Zeal. Jour. Sci. and Technol.*, 19 (1938), No. 12, pp. 750-761, figs. 5).—Important insect pests of eucalyptus in New Zealand dealt with are *Eriococcus coriaceus* Mask., *Goniapterus scutellatus* Gyll., *Paropsis dilatata* Er., and *Rhinoniphetella eucalypti* Gahan.

Intermediary arthropod hosts and mechanical carriers of human disease in the Australian region, F. H. TAYLOR (*Health [Austral.]*, 16 (1938), No. 8, pp. 72-82, fig. 1).—This is a tabulated summary of information.

The fate of certain European insects introduced into Australia for the control of weeds, G. A. CURRIE and R. V. FYFE (*Jour. Council Sci. and Indus. Res. [Austral.]*, 11 (1938), No. 4, pp. 289-301).—An account is given from observations of the behavior and fate of phytophagous insects that since 1929 have been imported into Australia from England and France for the control of introduced weeds, St. John's wort and ragwort. The several introduced species released thus far have disappeared after a shorter or longer period, although liberations have been made over a period of years in many different places within the weed-infested areas. "The ease with which some phytophagous insects have been established in new countries, as compared with the difficulty experienced with others, is discussed, and evidence is presented supporting the generalization that, if a phytophagous insect is able to adapt itself and thrive in a new environment, it will probably do so from the early liberations of relatively small numbers."

Notes on entomogenous fungi, T. PETCH (*Brit. Mycol. Soc. Trans.*, 16 (1931), pt. 1, pp. 55-75, figs. 4; 16 (1932), pt. 4, pp. 209-245, figs. 8; 18 (1933), pt. 1, pp. 48-75; 19 (1935), pt. 3, pp. 161-194, figs. 7; 21 (1937), pt. 1-2, pp. 34-67).—A genus (*Ophiocordyceps*) is erected and many forms are described as new to science in these notes on over 100 insect-attacking fungi.

Preliminary observations on the gaseous environment of *Eutermes exitiosus* Hill (Isoptera), M. F. DAY (*Jour. Council Sci. and Indus. Res. [Austral.]*, 11 (1938), No. 4, pp. 317-327, figs. 6).—It was found that a concentration of carbon dioxide approximately 50 times that of the normal atmosphere, while injurious to many animals, is the normal environment of certain termites.

Descriptions of Nearctic caddis flies (Trichoptera), with special reference to the Illinois species, H. H. ROSS (*Ill. Nat. Hist. Survey Bul.*, 21 (1938), Art. 4, pp. III-101-183, pl. 1, figs. 123).—Many new forms of caddis flies are described and two genera and three subgenera erected for Trichoptera from Illinois and elsewhere.

Qualitative and quantitative changes in radiosensitivity of grasshopper eggs during early development, T. C. EVANS (*Physiol. Zool.*, 9 (1936), No. 4, pp. 443-454, pl. 1, figs. 3).—The results of experiments in which grasshopper eggs of different ages were irradiated and examined at the time of diapause are reported.

Grasshopper eggs and their larval predators show high degree of survival, J. A. MUNRO (*North Dakota Sta. Bmo. Bul.*, 1 (1939), No. 3, pp. 3, 4).—A brief reference is made to an attempt to determine the effect of drying and prolonged storage at low temperatures on the viability of grasshopper eggs and their larval predators. The results indicated that while dryness seriously impaired the viability of both the eggs and the larval predators it is probable that they are seldom exposed to such severe conditions. The results show that the same factors which affect the development of grasshopper eggs also affect the welfare of their predaceous enemies, the bee fly and blister beetle larvae, and in much the same manner.

Oxygen consumption and rates of dehydration of grasshopper eggs (Orthoptera). V. THOMPSON and J. H. BODINE (*Physiol. Zool.*, 9 (1936), No. 4, pp. 455-470, figs. 10).—Determination of the water loss of the differential grasshopper at different developmental periods has shown no qualitative difference between wet (with hypertonic solutions) and dry (calcium chloride) dehydration. "The resistance to desiccation decreases with morphological age of developing eggs. Diapause eggs are most resistant. The rate of desiccation does not seem to be closely associated with metabolic activity, as represented by that fraction of the respiration which is dependent on structure, or which may be depressed by certain CO₂/O₂ mixtures. The oxygen consumption of dehydrated eggs decreases during water loss. In no case was an increase observed during dehydration. The vital limit of desiccation of postdiapause eggs at 25° C. was found to be about 46 percent of the initial water."

A list of 31 references to the literature is included.

The egg parasite of the plague grasshopper: Value as a factor in control. N. S. NOBLE (*Agr. Gaz. N. S. Wales*, 49 (1938), No. 3, pp. 143-146, 156, figs. 7).—Further observations (*El. S. R.*, 74, p. 825) on the scellionid egg parasite *Scelio fulgidus* made during the grasshopper plague in Australia in 1937-38 are reported. There is said to be no evidence at present to show that this parasite breeds in the eggs of any species other than the plague grasshopper *Chortoicetes terminifera*.

Studies of contact insecticides.—XIII, The blood of the cockroach *Periplaneta americana* L.: Cell structure and degeneration and cell counts. H. W. SMITH (*New Hampshire Sta. Tech. Bul.* 71 (1938), pp. 23, figs. 9).—In continuation of these studies (*El. S. R.*, 73, p. 75) investigation was made of the blood of the American cockroach. A simple and constant blood cell picture was observed. The various forms described by many authors in other insects not having been found, they are considered to represent in part the results of coagulation-break-down phenomena. "The acetic acid vapor treatment facilitated study of the normal cell structure by its fixative action and was used as a standard procedure. Blood was drawn from the coxofemoral leg joints. The blood cells of the cockroach are elongated and flat with uniform and well-defined outlines. Their size is about 25 μ by 10 μ . No dividing cells were found. The break-down of cell structure in the process of coagulation causes many abnormal forms. A study of the rounding and disintegration of cells in coagulation has simplified differentiation between normal and abnormal cell structures. The average blood cell count was 88,755 cells per cubic millimeter. Analysis of cell counts, however, showed the principal mode in the frequency of cell count distribution to be the 70,000 group. There was no significant difference in the average counts of males, females, and large nymphs. The total cell count for adult cockroaches was determined as approximately 16,500,000."

A 5-page list of references to the literature is included.

The nutritional requirements of *Blattella germanica*. C. M. MCCAY (*Physiol. Zool.*, 11 (1938), No. 1, pp. 89-103, figs. 3).—Methods devised for the use of the German cockroach in nutrition studies are considered. The conversion of matter into body tissue by this cockroach indicates that it is nearly three times as efficient as domestic animals, such as swine. An extensive series of tests to determine the vitamin needs of this insect indicates that it must have certain essential factors found in yeast.

Nutrition studies with the cockroach *Blattella germanica*. R. M. MELAMPY and L. A. MAYNARD (*Physiol. Zool.*, 10 (1937), No. 1, pp. 36-44, fig. 1).—A report on a nutritional study of the German cockroach, which was selected because of its omnivorous feeding habits, incomplete metamorphosis, fast growth rate, and rapid reproduction.

Report on the Hemiptera-Heteroptera taken in the light trap at Rothamsted Experimental Station during the four years 1933-1936, D. C. THOMAS (*Roy. Ent. Soc. London, Proc., Ser. A, 13 (1938), No. 1-3, pp. 19-24, fig. 1*).—Collections in a light trap with a 300-c. p. electric light, set about 3.5 ft. above the level of the ground and kept continuously in use at the Rothamsted Experimental Station from March 1933 to February 1937, are reported upon. The details are given in tables.

Use of sulphur dioxide against the bedbug, H. C. GOUGH (*Nature [London], 141 (1938), No. 3560, p. 164*).—Using a fumigation apparatus the author exposed different stages of the bedbug for 2.5 hr. to known concentrations of sulfur dioxide under controlled conditions of temperature and humidity. The results, expressed as the amount of this gas required to give a complete kill of each stage at 23° C. and 60 percent relative humidity, are summarized in table form. It appears that the egg, especially just after its deposition, is considerably more resistant than either the adult or any nymphal instar, and that this resistance gradually decreases as the time of hatching approaches.

Lygus hesperus Knight and *Lygus elisus* Van Duzee in relation to alfalfa-seed production, C. J. SORENSON (*Utah Sta. Bul. 284 (1939), pp. 61, figs. 15*).—Studies of tarnished plant bugs in Millard County and the Uinta Basin, namely, *L. hesperus* and *L. elisus*, are reported, the details being given in 29 tables. These bugs were found to be the most abundant insect inhabitants of alfalfa-seed fields, with the exception of thrips, during the bloom period and to increase significantly the occurrence of blasted buds, blossom drop, and shriveled seed during the production of an alfalfa seed crop. The degree of injury generally varied directly with the intensity of the bug infestation. The observations indicate that while *Lygus* bugs are a major factor in causing bud blasting, shriveled seeds, and perhaps other pathological conditions adversely affecting seed development in alfalfa, they are not exclusively responsible for these phenomena. Although infesting an unusually wide range of plants in the State, alfalfa appears to be the choicest host plant of these bugs. Both species pass the winter in the adult stage, hibernating in or near the fields under debris, weeds, grass, and crop litter. Activity begins in early spring. In alfalfa most eggs are laid in the terminal 2 in. of the stems. "The incubation period of *Lygus* eggs was found to vary with weather conditions, lower temperatures requiring longer periods. Mean lengths of this period were found to be 12.85 days for 341 eggs in 1931, 13.03 days for 147 eggs in 1932, and 14.93 days for 183 eggs in 1933. The mean time necessary for development from freshly laid eggs to the emergence of adults was found to be as follows: 1931, 37.87 days; 1932, 37.53 days; 1933, 34.15 days. With a preoviposition period approximating 10 days, the total time necessary for the production of each brood of bugs approached 46 days. Data obtained in life history studies indicated the development in Utah of three to five broods annually, varying with the character of growing seasons and climatic conditions in different sections of the State."

Experimental tests of various insecticides have indicated that they are not effective in either destroying or repelling these bugs. None has been discovered that has proved adequate, economical, or practical in controlling them in alfalfa. Some measure of prevention and control of these injurious insects may be obtained by practicing good farm sanitation in keeping ditchbanks, fence lines, roadways, waste places, and all cultivated land free from weeds and crop litter. If such material does accumulate it should be burned in the fall so that it will not afford hibernation quarters for overwintering adult bugs. It is pointed out that seed growers of an entire community or a seed-growing district should adopt a uniform practice with respect to selecting either all first- or all second-growth alfalfa

for the production of the seed crop, as simultaneous occurrence of both first- and second-crop alfalfa provides *Lygus* bugs with most favorable conditions for multiplication.

A list of 21 references to the literature cited is included.

The apple leaf jassid in South Australia, I. H. K. KEMP (*Jour. Dept. Agr. So. Austral.*, 42 (1938), No. 4, pp. 394-401, figs. 6).—The apple leaf jassid *Typhlocyba australis* Frogg. has been found in South Australia feeding on the apple, pear, plum, quince, and the deciduous hawthorns. In control work 40 percent nicotine sulfate at 1 in 800 gave efficient control, the spray killing both by direct contact and by the fumigant effect.

An insect vector of the dwarf disease of rice plant, T. FUKUSHI (*Imp. Acad. [Japan] Proc.*, 13 (1937), No. 8, pp. 328-331, fig. 1).—In addition to *Nephotettia apicalis* Motsch. var. *cincticeps* Uhl. (= *N. bipunctatus cincticeps*), long supposed to be the sole agent in the transmission of dwarf disease of rice, *Deltocephalus dorsalis* Motsch. was found to be a vector.

Kenya coffee mealy bug research, A. R. MELVILLE (*East African Agr. Jour.*, 3 (1938), No. 6, pp. 411-422, figs. 2).—Report is made of a study of *Pseudococcus kenyae* LeP., a serious pest of coffee and native crops in the Central Province of Kenya which has been introduced into the area without specific natural enemies.

Further studies on the relationship between *Hyoscyamus virus 3* and the aphid *Myzus persicae* (Sulz.), with special reference to the effects of fasting, M. A. WATSON (*Roy. Soc. [London], Proc., Ser. B*, 125 (1938), No. 858, pp. 144-170).—A study conducted at the Rothamsted Experimental Station (E. S. R., 76, p. 805) has shown that the green peach aphid is much more likely to transmit the *Hyoscyamus virus 3* if made to fast immediately before being fed on the source of infection. Its efficiency as a vector increases rapidly during the first hour of fasting, but long periods of starving give but little further increase in infectivity. Infectivity was found to be lost by the aphids after the cessation of infection feeding, and the rate of loss was probably more rapid than the rate at which the virus deteriorates in vitro.

Horticultural aspects of woolly aphis control, together with a survey of the literature, R. M. GREENSLADE (*Imp. Bur. Fruit Prod. [East Malling, Kent.], Tech. Commun.* 8 (1936), pp. 88).—Following a foreword by R. G. Hatton and a brief introduction, the woolly apple aphid is dealt with under the headings of the insect and its habits (pp. 7-12), effect of climate (pp. 12, 13), control (pp. 13-27), and economic importance (p. 27). A bibliography of 49 pages is included, as is an appendix consisting of a memorandum and questionnaire on the incidence and control of the woolly apple aphid.

Hibernation of the corn ear worm in southern Connecticut, G. W. BARBER (*Connecticut [New Haven] Sta. Bul.* 419 (1939), pp. 27).—Report is made of experiments commenced in the fall of 1935 and continued until the spring of 1938 with a view to determining the source of infestation of the corn earworm in southern Connecticut, the details being given in 13 tables. It was found that annual populations began with a few individuals which occurred in the earliest sweet corn during June or July. Populations which occurred during August and September could be traced to natural increases from these first-occurring individuals, when considered in connection with the corn acreage attractive to the ovipositing moths during the season. "Most pupae were found at depths of from 2 to 4 in. below the surface of the soil, but they occurred deeper in sandy than in other soils. Progressive destruction of the emergence burrows, which are dug by the larvae to enable the moths to escape from the soil, occurred in outdoor cages from the time the insects entered hibernation during September until the following summer. Destruction of these burrows was due to several factors, of

which freezing and thawing of the soil, the activity of earthworms, and growth of roots of plants were the most important. Pupae survived the winter in sandy soil at West Dennis, Mass., during 2 yr. and in washed sand at Milford, Conn., during 1 yr. They also survived in cages located in the soil of an open shed at Mount Carmel, Conn., 1 yr. In locations protected from precipitation and extreme ranges in temperature they survived in large numbers. Moths emerged during summer from these locations. It was concluded that the insect survived the winter in certain environments in southern New England at least during some years. The number of survivors seemed adequate to account for the annual infestations that have occurred."

The overwintering pupa of *Heliothis armigera* Hubn. (obsoleta Fabr.).—I, Effect of temperature and moisture, E. PARRY JONES (*Brit. So. Africa Co. Pub. 6* (1937), pp. 19–36, figs. 2).—A continuation of studies of the bollworm previously noted (E. S. R., 79, p. 224).

Two egg parasites of the cotton boll worm (*Heliothis armigera* Hubn. (obsoleta Fabr.)) in Southern Rhodesia, E. PARRY JONES (*Brit. So. Africa Co. Pub. 6* (1937), pp. 37–105, pls. 3, figs. 3).—Investigations conducted with two of the indigenous egg parasites of the bollworm in Southern Rhodesia, *Telenomus ullyetti* Nixon and *Trichogramma lutea* Gir., are reported.

Larval dispersion of *Diatraea saccharalis*, R. W. E. TUCKER (*Agr. Jour. [Barbados]*, 6 (1937), No. 4, p. 157–169 figs. 4).—Report is made of a series of plat experiments conducted in 1935, 1936, and 1937 in which the number of sugarcane borer eggs laid in sterilized soil was found to be very little different from the number laid in normal plats and showed moth dispersal.

Notes on the biology of *Cacoecia longicellana* Walsingham, S. NAKAYAMA (*Ohosen Govt. Gen. Agr. Expt. Sta. Ann.*, 9 (1937), No. 3, pp. 417–424, pl. 1; *Eng. abs.*, p. 423).—Report is made of a study of the biology and control of the apple leafhopper *C. longicellana*, which, with *C. xylosteana* L., a second important pest, attacks both leaves and fruit, particularly in the northern and western apple-growing sections of Chosen (Korea).

Phlyctaenodes bifidalis (Fab.), a new pest of cotton in Brazil (Lepidoptera: Pyraustinae) [trans. title], H. F. G. SAUER (*Arch. Inst. Biol. [São Paulo]*, 8 (1937), pp. 201–210, pls. 2, figs. 3; *Eng. abs.*, p. 209).—Report is made of biological studies of the pyralid *P. bifidalis*, a new pest occurring on cotton in the State of São Paulo. Recommendations for control include the destruction of the common host plants *Amaranthus hybridus*, *A. spinosus*, *Talinum patens*, and *Portulacca oleracea*.

Codling moth control: Results of tests at Young, S. L. ALLMAN (*Agr. Gaz. N. S. Wales*, 49 (1938), No. 4, pp. 217–220, 230, figs. 2).—Reporting further upon codling moth control work (E. S. R., 74, p. 821), lead arsenate plus white oil is said to have given the best control. White oil plus nicotine sulfate gave good results, and the spray residue was kept within reasonable limits.

Codling moth and Williams pears: Control methods investigated, R. T. M. PESCOFF and L. W. MILLER (*Jour. Dept. Agr. Victoria*, 35 (1937), No. 10, pp. 501–512, figs. 9).—This is a progress report of investigations of codling moth injury to the Williams Bon Chretien variety of pear, the only canning variety in the Goulburn Valley, conducted during the year 1936–37. On the experimental plat at Maroopna the infestation ranged from a minimum of 5.49 to a maximum of 11.1 percent, with an average infestation of 8 percent over the whole block of more than 1,000 trees. The results of life history studies and control experiments (including spraying in the field and bandaging) are reported upon at length, the details being given in 14 tables.

"In the spraying experiments in the field eight different spray programs were used, the minimum codling moth infestation of 5.49 percent being obtained with a spray program consisting of two calyx and two cover sprays of arsenate of lead (8 lb. to 80 gal. of water). However, there was no significant difference in the control observed with this program and with one of the same number of sprays of arsenate of lead (5 lb. to 80 gal. of water)."

Codling moth and Williams pears: Goulburn Valley investigations, L. W. MILLER (*Jour. Dept. Agr. Victoria*, 36 (1938), No. 11, pp. 545-561, 572, figs. 12).—A continuation during the 1937-38 fruit season of the control investigations noted above.

The occurrence of the pink bollworm in the floral parts of the cotton plant in São Paulo during 1936-37 [trans. title], E. J. HAMBLETON (*Arch. Inst. Biol. [São Paulo]*, 8 (1937), pp. 249-254, pls. 2; *Eng. abs.*, p. 253).—The occurrence of the pink bollworm in the floral parts of the cotton plant is reported for the first time in the State of São Paulo. A brief note is given on the activity of the insect and the nature of its attack in the cotton buds and flowers during the season of 1936-37.

Nocturnal habits of *Platyedra gossypiella* Saunders, F. A. SQUIRE (*Nature [London]*, 140 (1937), No. 3532, pp. 69, 70, figs. 2).—Reference is made to observations of the pink bollworm, particularly in the British West Indies, where at St. Vincent light attraction is evident from 8 p. m. to 4 a. m.

An outbreak of *Synnoma lynosyrana* Walsingham (Tortricidae, Lepidoptera), D. J. PLETSCHE (Mont. State Col.). (*Ent. News*, 49 (1938), No. 8, p. 231).—Reference is made to an outbreak in August 1937 of larvae of the tortricid *S. lynosyrana* on rabbit brush (*Chrysothamnus* sp.) growing on range land in Beaverhead County, Mont. The species is known to occur in California, New Mexico, Colorado, and Arizona as well as in Montana.

The effect of delayed fertilisation on the sex ratio of a species of insect in which the female is the heterogametic sex, *Ephestia kühniella* Zell. (Lepid.: Phycitidae), H. C. JAMES (*Roy. Ent. Soc. London, Proc., Ser. A*, 12 (1937), No. 7, pp. 92-98).—Details of studies conducted with the Mediterranean flour moth are given in four tables. A list of nine references to the literature is included.

Nutritional studies of the webbing clothes moth (*Tineola bisselliella* Hum.), M. F. CROWELL and C. M. McCAY (*Physiol. Zool.*, 10 (1937), No. 3, pp. 368-372).—The authors find that the nutritional requirements of the webbing clothes moth, in spite of its peculiar feeding habits in nature, may be satisfied by a purified diet consisting of casein, lactalbumin, Harris B concentrate, and fish-meal ash. The value of the fish-meal ash is questionable. Part, or all, of the vitamin B complex is essential for its growth and development. It requires neither fat nor the fat-soluble vitamins. Purified casein is not an adequate protein for the optimum development of the larvae, but purified lactalbumin supplements the casein satisfactorily. The addition of cystine to the casein does not markedly improve its quality.

Indo-Malayan and Papuan microlepidoptera.—I, Notes on the tropical tobacco moth *Setomorpha rutella* Zeller (Tineidae), A. DIAKONOFF (*Traubia [Buitenzorg]*, 16 (1938), No. 3, pp. 399-414, figs. 10).—These notes relate to the biology and economic importance of *S. rutella*, a well-known pest of various animal and vegetable products which has a circumtropical distribution, being particularly injurious to cured tobacco leaves in the Dutch East Indies. It is known to occur in Hawaii, Texas and Kansas in the continental United States, Central America, South America, and the West Indies, as well as in Asia.

Some notes on the hunchback fly *Phora incrassata* Mg., F. THOMPSON (*Bee World*, 19 (1938), No. 2, pp. 19, 20, figs. 3).—These notes consist of a brief review of the literature and indicate that the so-called hunchback fly *P. incrassata* may be a parasitic as well as a saprophytic enemy of bee brood.

Humpbacked flies and the honey bee, Z. Ö. PAL (*Bee World*, 19 (1938), No. 6, pp. 64-68, figs. 5).—These notes from the literature, with 26 references, and personal observations supplement the account by Thompson above noted. Further evidence is presented that the so-called hunchback fly may act as a parasite of bee brood. It is shown that *Borophaga* (*Phora*, *Peromitra*) *incrassata* is the correct name of this phorid.

The British mosquitoes, J. F. MARSHALL (*London: Brit. Mus. (Nat. Hist.)*, 1938, pp. XI+341, pls. 20, figs. 172).—This work on the morphology, biology, and control of mosquitoes includes a bibliography of 208 titles.

Graphic reproduction of the life cycle of the malaria parasite in the mosquito host, B. MAYNE (*U. S. Pub. Health Serv., Natl. Inst. Health Bul.* 170 (1938), pp. III+15, pls. 27).—The author reviews the life history of the malaria gamete and traces its development from the simple one-celled ameba-like sporozoan in the blood cell of the human host to the multicellular encysted zygote with its mass of pointed spindles, which, migrating to the salivary glands of the winged carrier, rounds out the infective cycle.

Malaria in the Netherlands, N. H. SWELLENGREBEL and A. DE BUCK (*Amsterdam: Scheltema & Holkema*, 1938, pp. VIII+267, pls. 2, figs. 23).—This work includes chapters relating to disease-carrying mosquitoes as follows: The races of *Anopheles maculipennis*, behavior of the short-winged *A. maculipennis*, anopheline malaria, transmission of the malaria parasite from mosquito to man, transmission of the malaria parasite from man to mosquito, and malaria control.

Biology and general morphology of *Leucopis griseola* Fall. (Chamaemyiidae, Diptera), an important predator of *Aphis gossypii*, and some other aphid pests of crops, H. S. PRUTHI and H. L. BHATIA (*Indian Jour. Agr. Sci.*, 8 (1938), No. 5, pp. 735-740, pl. 1).—The chamaemyid dipteran *L. griseola*, an important predator of the cotton aphid feeding largely upon the young aphids, was discovered for the first time in India at Delhi. Notes are given on its habits and economic status, and a description of and the duration of the stages in its life history, together with an illustration of the several instars in colors. The predator larvae have also been found at Delhi preying on the English grain aphid, the green peach aphid (infesting potato), and some unidentified aphids found on hollyhock, palak, mustard, etc.

Studies on warble-flies of Manchuria and Inner Mongolia, S. ONO (*Kitasato Arch. Expt. Med. [Tokyo]*, 15 (1938), No. 3, pp. 199-246, pls. 8, figs. 3).—This contribution deals with general aspects of warble fly life; morphology and bionomics; experimental studies (1) of the migration course of the larva in cattle and (2) on the perforation of the skin by the larva; the action of hypodermatotoxin on the germinal cells of the experimental animal which produces abnormal offspring; and the development of warble fly larvae in various experimental animals. It is concluded that both the common cattle grub and the northern cattle grub occur in Manchuria and Inner Mongolia.

The reactions of the housefly (*Musca domestica* Linn.) to light of different wave-lengths, J. W. M. CAMERON (*Canad. Jour. Res.*, 16 (1938), No. 11, Sect. D, pp. 307-342, figs. 24).—The details of the studies conducted are presented in 16 tables and 24 figures. A list of 102 references to the literature is included.

Studies on the chemotropic behaviour of sheep blowflies, M. R. FENEY (*Austral. Council Sci. and Indus. Res. Pam.* 74 (1937), pp. 24, pl. 1, figs. 3).—

Report is made of a study of the chemotropic responses of sheep blowflies in which the attractiveness of a bait to any species was assumed to be proportional to the number of that species trapped.

A new blowfly attacking sheep in western Scotland, J. MacLEOD (*Nature [London]*, 138 (1936), No. 3489, pp. 467, 468).—The author reports having found that *Phormia terrae-novae* R. D., a species widely distributed in Europe and North America, acts as a primary blowfly of sheep in western Scotland, initiating strike on relatively clean-wooled areas. While closely related to the important black blowfly (*P. regina*) of sheep in North America, *P. terrae-novae* had not been recorded previously from any country as attacking sheep.

Losses due to the sheep blowfly, M. J. MACKERRAS (*Jour. Council Sci. and Indus. Res. [Austral.]*, 11 (1938), No. 2, pp. 97–102).—Data are given on losses caused by the sheep blowfly *Lucilia sericata* throughout the world.

Biological and systematic notes and records of South African Trypetidae (fruit-flies, Diptera), with descriptions of new species, H. K. MUNRO (*Union So. Africa Dept. Agr., Ent. Mem.* 9 (1935), pp. 18–59, figs. 10).—The data considered supplement those previously reported (*E. S. R.*, 69, p. 686). A new subgenus is erected, and descriptions are given of 11 species and 1 variety new to science.

Olfactory attractants for male fruit-flies, L. B. RIPLEY and G. A. HEPBURN (*Union So. Africa Dept. Agr., Ent. Mem.* 9 (1935), pp. 3–17).—This is a report of studies of the olfactory reactions of the Natal fruitfly *Ceratitis (Pterandrus) rosa* Ksh. to baits of certain chemicals conducted over a period of several years with a view to discovery of superior baits and repellents (*E. S. R.*, 67, p. 426). It is concluded that the fruitfly is probably attracted to fruits and fermenting baits by composite odors rather than by any one chemical compound occurring in them.

Fruit fly investigations, 1935, H. W. SIMMONDS (*Fiji Dept. Agr. Bul.* 19 (1936), pp. [1]–18, pls. 4).—A preliminary account is given of investigations of the bionomics of Filian fruitflies, three in number, namely, *Chaetodacus passiflorae* Frogg., *C. xanthodes* Broun, and *Chaetodacus* sp. near *distinctus* Mall., including the life history of *C. passiflorae*, the most important species, and several of its natural enemies.

Factors in varietal susceptibility of walnut fruits to attack by the walnut-husk fly, A. R. C. HAAS (*Plant Physiol.*, 12 (1937), No. 3, pp. 721–736, figs. 6).—In this study the importance of husk hardness as a factor is confirmed, and it is shown that there is a relation between this and other physicochemical properties of husks in the different varieties.

The control of cabbage root fly (*Delia (Hylemyia) brassicae* Bouché), D. W. WRIGHT (*Jour. Min. Agr. [Gt. Brit.]*, 45 (1938), No. 8, pp. 812–820, pls. 2).—The experiments reported suggest that the cabbage maggot on cabbage plants can be most effectively controlled by two applications of a 4-percent calomel dust.

The cineraria leaf miner *Phytomyza atricornis* damages parks and private gardens, C. R. WALLACE (*Agr. Gaz. N. S. Wales*, 49 (1938), No. 2, pp. 75, 76, 79, figs. 2).—It is concluded that the agromyzid leaf miner *P. atricornis*, which causes extensive damage to cineraria in the Sydney district, can be controlled by spraying at intervals of 8 or 9 days with nicotine sulfate 1:400 and soft soap. It is pointed out that both surfaces of the leaves should be thoroughly wetted by the spray.

Researches on the Colorado potato beetle.—IV, Acclimatization of the American entomophagous insect enemies of the Colorado potato beetle [trans. title], J. FERTAUD (*Ann. Épiphyt. et Phytogénét.*, n. ser., 4 (1938), No. 1, pp. 27–93, figs. 25).—A continuation of a previous contribution (*E. S. R.*, 78, p. 226).

Control of the longhorn beetle *Stromatium fulvum* (Villers) on valuable furniture in Egypt, M. SHAFIK (*Egypt Min. Agr., Tech. and Sci. Serv. Bul.* 182 (1938), pp. [1]+9, pls. 4).—This contribution relates to a beetle occurring in the whole Mediterranean region, southern Russia, and Turkey which attacks dry hardwood and can pass its life cycle in furniture, window frames, doors, and other manufactured wood.

A report on the intestinal protozoa of the larva of the Japanese beetle (*Popillia japonica* Newm., Coleoptera), S. A. KOWALCZYK (*Amer. Micros. Soc. Trans.*, 57 (1938), No. 3, pp. 229-244, figs. 21).—Report is made of a study of the intestinal material from 50 infected larvae of the Japanese beetle, collected from 3 localities, which disclosed species of 5 genera of Mastigophora, 2 of Sarcodina, and 1 genus of Sporozoa. A list is given of 45 references to the literature cited.

Morphology and bionomics of immature stages of Japanese chafer beetles.—I, *Anomala cuprea* (Hope), H. YUASA and T. ENDŌ (*Jour. Imp. Agr. Expt. Sta., Nisigahara, Tokyo, Japan*, 3 (1938), No. 2, pp. 151-182, pls. 2, figs. 5: *Eng. abs.* pp. 180, 181).—This contribution, dealing with the results of the investigation of *A. cuprea*, is the first report of studies on the morphology and bionomics of the immature stages of the scarabaeid beetles common in the environs of Tokyo.

The sand wireworm and its control in the South Carolina Coastal Plain, J. N. TENNET and E. W. HOWE (*U. S. Dept. Agr., Tech. Bul.* 659 (1939), pp. 39, figs. 17).—Studies, commenced in 1930, of the sand wireworm, known for nearly 25 yr. as a serious pest of corn, cotton, cowpeas, and other crops of the Coastal Plain of South Carolina and in other restricted parts of the country, are reported. The pest has a 1-yr. life cycle in the State, with approximately 12 days passed in the egg stage, 352 days in the larval stage, 11 days as a pupa, and, in the laboratory, from 10 to 14 days as an adult. No important natural enemies were found during the investigation, nor have any been reported. Direct control of this insect is not practical, but a large measure of relief from the pest can be obtained by the following practices: Land resting, attention to favorable planting dates, avoidance of attracting the egg-laying female beetles, and building up soil fertility with humus. An acceptable crop rotation has been very successful.

The control of scarabee (*Euscepes batatae* Waterh.) in Barbados, R. W. E. TUCKER (*Agr. Jour. [Barbados]*, 6 (1937), No. 4, pp. 133-156).—A detailed account is given of the life history of the West Indian sweetpotato weevil, attention being drawn to the protected hidden singly laid eggs, low life cycle mortality, high reproductive capacity, and hardness of the adult beetles. Only one alternate host plant, restricted to the seashore, is known in Barbados, and no natural enemies have been observed.

Control experiments conducted over a period of 3 yr. showed in all cases that three consecutive sprayings of the potato vines with lead arsenate plus a sticker reduced infestation and increased yields to an outstanding extent.

The bark beetles of Minnesota (Coleoptera: Scolytidae), H. R. DODGE (*Minnesota Sta. Tech. Bul.* 132 (1938), pp. 60, pls. 4).—Following a brief introductory account, the economic importance, control measures, natural control, life history and habits, and galleries of the scolytid beetles of Minnesota are considered and field keys to the galleries of these beetles, of which 64 species occur in the State, presented. Reference is made to the morphological characters, and a key given to the genera known or likely to occur in Minnesota is followed by notes on the species including a key for their separation giving name or other synonymy, host, morphological characters, and biology when known. A bibliography of three pages is included.

A cytological study of the gregarine parasites of *Tenebrio molitor*, using the ultra-centrifuge, M. I. DANIELS (*Quart. Jour. Micros. Sci. [London]*, n. ser., 80 (1938), No. 318, pp. 293-320, pl. 1, figs. 2).—Three gregarine species were found by the author to inhabit the midgut of larvae of the yellow mealworm, namely, *Gregarina cuneata* Stein, *G. polymorpha* Hamm, and *G. steini* Berndt. The contribution is accompanied by a list of 45 references to the literature.

The strawberry crown borer (*Tyloderma fragariae* (Riley)), P. O. RITCHIE (*Kentucky Sta. Bul.* 389 (1939), pp. 35, figs. 11).—A study commenced in February 1937 of the morphology, biology, and natural enemies of and control measures for the strawberry crown borer, the worst insect pest of this crop in the State for 40 yr., is reported. Work was conducted in the counties of McCracken, Ballard, Caldwell, Lyon, and Fayette, and the report includes several records made by H. Garman in earlier years. In addition to the cultivated strawberry, the crown borer was found breeding in common cinquefoil, which is abundant and often the source of infestation for nearby berry patches, and in the wild strawberry. Usually passing the winter in the adult stage under trash or in the soil, it commences egg laying early in March. A very few crown borers pass the winter within infested plants and mature in February and March. The eggs, of which 142 was the maximum number produced by a female, are always laid in the strawberry plant, usually being deposited in excavations made in the crown or old leaf bases slightly above the origin of the lateral roots and close to the soil surface. Plants attacked by the larvae are killed, stunted, or may show no other effects except a reduction in number of runners and runner plants. In dry years entire fields are often destroyed by the crown borer. In western Kentucky pupation commenced between June 10 and 16 in 1937 and 1938. The first-generation adults began emerging late in June. In 1937 a small second generation was reared at Princeton. One parasite, *Microdrakon analcidis* Ashm. and two predators, *Monocrepidius auritus* Herbst and *Hister americanus* Payk. were found attacking the crown borer. *Tyloderma foveolata* (Say), a close relative of the crown borer, was common in strawberry patches, but breeds in *Oenothera lacinata* Hill and is not a strawberry pest.

The results obtained from insecticides and barriers tested as means of control do not warrant their use. The work has led to the recommendation that (1) new strawberry patches be set at least 350 yd. from a source of infestation, (2) plants for new patches be dug between December 1 and March 1, (3) preference be given to certified plants for setting new patches, (4) strawberry patches be set only on land in cultivation for 1 or more years, (5) all berry patches be destroyed after the second year of picking, and (6) the common cinquefoil be destroyed.

A list is given of 19 references to the literature.

The banana beetle borer: Investigations and control measures, R. WALLACE (*Agr. Gaz. N. S. Wales*, 48 (1937), No. 11, pp. 621-623, 638, fig. 1).—This contribution gives a generalized account of the main conclusions drawn from experiments extending over the past 4 yr. on the banana root borer, a weevil found in most banana-growing countries of the world. The beetle has been shown to have a decided preference for dead or spent plant material. The best control measure consists of the provision of good growing conditions.

The granary weevil (*Calandra granaria* L.): Its biology and control [trans. title], K. T. ANDERSEN (*Monog. Angew. Ent.*, No. 13 (1938), pp. 108, pl. 1, figs. 36).—A report of studies of the biology and control of this insect, presented with a list of 86 references to the literature.

The embryonic development of *Calandra oryzae*, O. W. TIGGS and F. V. MURRAY (*Quart. Jour. Micros. Sci. [London]*, n. ser., 80 (1938), No. 318, pp. 159-284, pls. 6, figs. 19).—This contribution is accompanied by a list of 97 references to the literature.

The histology of larvae affected with European foul brood, H. L. A. TARR (*Bee World*, 19 (1938), No. 5, pp. 56-59, figs. 8).—The author presents a series of photomicrographs illustrating the manner in which *Bacillus pluton* invades the bee larva and develops at different stages of the disease.

Honeybee monstrosities, J. E. ECKERT. (Univ. Calif.). (*Amer. Bee Jour.*, 78 (1938), No. 11, pp. 504, 505, fig. 1).

Host-selection in *Pimpla examinator* F. (Hymenoptera), D. J. JACKSON (*Roy. Ent. Soc. London, Proc., Ser. A*, 12 (1937), No. 7, pp. 81-91, pl. 1).—Following a list of the recorded hosts of the parasite *P. examinator*, its life history is summarized and a description given of the habit of the female in puncturing pupae for feeding and oviposition, presented with a list of 19 references to the literature.

The Nearctic species of *Netelia* (*Paniscus* of authors) and a revision of the genera of *Neteliini* (Hymenoptera, Ichneumonidae), H. K. TOWNES, JR. (Cornell Univ.). (*Lloydia*, 1 (1938), No. 1-4, pp. 168-231, pls. 8).—A revision of a group of ichneumonids that are external parasites upon lepidopterous larvae. Seventy-nine forms are recognized, of which 53 species and 2 subspecies are described as new to science.

Euplectrus agaristae Craw.: A parasite of the grape vine moth *Phalaenoides glycine* Lew., N. S. NOBLE (*N. S. Wales Dept. Agr., Sci. Bul.* 63 (1938), pp. 27, figs. 9).—An account of the life history of *E. agaristae*, an external gregarious parasite of the larvae of the grapevine moth *P. glycinae* in New South Wales. This chalcidoid parasite of the family Eulophidae is said to be common in the Sydney district, and has also been taken at Maclean on the north coast and at Goulburn on the southern tablelands. A list of 33 references to the literature cited is included.

Rhaconotus scirpophagae Wlk., a parasite of the sugarcane white moth borer (*Scirpophaga*), M. C. CHERIAN and P. ISRAEL (*Madras Agr. Jour.*, 26 (1938), No. 4, pp. 127-134, pl. 1).—Information on the habits and life history of *R. scirpophagae*, its egg-laying capacity, longevity, etc., is presented, the details being given in four tables. It is said to be fairly efficient in the control of the sugarcane white moth borer (*Scirpophaga* sp.) under south India conditions.

The life cycle of *Nosema carpocapsae*, a new microsporidian parasite of the codling moth (*Laspeyresia pomonella* L.) [trans. title], A. PAILLOT (*Compt. Rend. Soc. Biol. [Paris]*, 127 (1938), No. 12, pp. 1138-1140).—This sporozoan parasite of the codling moth has been under observation by the author in France since 1936. The name *N. carpocapsae* is proposed. It appears to be of little importance as a means of natural control of the moth.

Life history notes on the crucifer sawfly, Y. W. DJOU (*Lingnan Sci. Jour.*, 17 (1938), No. 1, pp. 83-86, figs. 3; *Chin. ads.*, p. 86).—These notes relate to the biology of the crucifer sawfly (*Aithalia* sp.), which feeds on the leaves of water cress in China and also attacks Chinese kale.

A revision of the mites of the subfamily Tarsoneminae of North America, the West Indies, and the Hawaiian Islands, H. E. EWING (*U. S. Dept. Agr., Tech. Bul.* 653 (1939), pp. 64, figs. 25).—In this revision of the mites of the subfamily Tarsoneminae 31 forms, representing 3 genera (*Pseudotarsonemoides* Vitzthum, *Tarsonemus* Canestrini and Fanzago, and *Hemitarsonemus* n. g.) are recognized, of which 18 species are described as new to science. Locality and host records are given for each species. The group, which is widely distrib-

uted, being found throughout the warmer parts of the world, has long been recognized as of much economic importance because of the injury many of them cause to cultivated plants. Methods of collecting and mounting tarsonemid mites are described. The characters of taxonomic importance, including the segmentation and chaetotaxy of the fourth pair of legs, are discussed in detail. A key (1) to the 3 genera, (2) to the known males of North American species, and (3) to some of the females of North American species, of *Tarsonemus*, and a list of 35 references to the literature cited are included.

The European red mite and its control, P. GARMAN and J. F. TOWNSEND (*Connecticut [New Haven] Sta. Bul. 418 (1938), pp. 34, figs. 6*).—This account of the European red mite, which first attracted attention in Connecticut in 1920 and from 1930 to 1936 became abundant in apple orchards, deals briefly with its life history and habits, outbreaks, and the use of sprays, followed by a report of experimental results and field observations, the details being given in 17 tables. Suggestions based upon the work are offered to growers. These include a dormant or delayed dormant application of 3 or 4 percent oil if clusters of eggs are found frequently on the twigs or heavily infested centers appear on the twigs and branches. Use 1.25 percent white lubricating oil emulsion during the last week of June or the first week of July, combining lead arsenate for maggot control but omitting all sulfur. A list of 29 references to the literature is included.

A population study of the red-legged earth mite *Halotydeus destructor* in Western Australia, with notes on associated mites and Collembola, K. R. NORRIS (*Austral. Council Sci. and Indus. Res. Pam. 84 (1938), pp. 23, figs. 10*).—Studies of the earth mite *H. destructor* (Tucker), a predator of the lucerne flea *Sminthurus viridis* L. which caused severe damage to clover early in 1935, have shown three generations to occur during a season at Guildford, Western Australia.

The ticks of Brazil and some other South American republics [trans. title], H. B. ARAGÃO (*Mem. Inst. Oswaldo Cruz, 31 (1936), No. 4, pp. 759-844, pl. 1, figs. 5*).—It is stated that 45 well-established species of ticks, representing 8 genera, are recognized from Brazil, 29 representing the genus *Amblyomma*. Their importance is emphasized, as in addition to transmitting treponemiasis, piroplasmiasis, and anaplasmosis to several domestic animals in Brazil, ticks (*A. cajennense* Fab. and *A. striatum* Koch) are responsible for the transmission of Brazilian Rocky Mountain spotted fever. They also harbor the virus of yellow fever, and *A. cajennense* and *Ornithodoros rostratus* Aragão even transmit it in laboratory experiments.

The publication includes tables for the separation of the genera and species of ticks known to occur in Argentina, Bolivia, Colombia, Paraguay, and Venezuela, as well as Brazil, and a description of a new variety under the name *Argas persicus dissimilis*. Their life history, bionomics, distribution, etc., are considered, and a list is given of 57 references to the literature.

ANIMAL PRODUCTION

Abstracts of papers, 96th meeting, American Chemical Society (*Amer. Chem. Soc. Mtg., 96 (1938), Abs. Papers, pp. 16, 17; 3, 4, 7, 8, 9, 19, 25, 26, 27, 28*).—Abstracts of the following papers, dealing with subjects of significance in animal nutrition from the agricultural and food chemistry and biological chemistry sections, are noted: An Improved Method for the Determination of Carotene in Silage, by D. M. Hegsted, J. W. Porter, and W. H. Peterson, and Carotene and Vitamin A Content of Wisconsin Milks, by A. C. Dornbush, F. R. Olson, and

W. H. Peterson (both Univ. Wis.); The Petroleum-Phasic Carotenoids of Egg-Yolk, by W. J. Peterson, J. S. Hughes, and W. M. Proudft (Kans. State Col.); Chondroitin as a Growth Factor for the Chick, by R. E. Gray, H. E. Robinson, F. F. Chesley, and L. A. Crandall; Vitamin C in Fresh Milk as Related to Other Constituents of the Milk, and to the Stage and Persistency of Lactation, by C. H. Whitnah (Kans. Expt. Sta.); Fat Balance Studies With the Pullet on Fat-Low and Normal Rations, by W. C. Russell, M. W. Taylor, and H. A. Walker (N. J.); The Determination of Sugar Tolerance in the Chicken, by J. W. Cavett; Anemia Studies With Dogs, by V. R. Potter, C. A. Elvehjem, and E. B. Hart (Univ. Wis.); The Influence of Arsenic in the Diet on the Toxicity of Seleniferous Grain, by A. L. Moxon (S. Dak. State Col.); and The Effect of High Temperatures on the Blood Calcium of Laying Hens, by R. M. Conrad.

[Livestock investigations in Alabama] (*Alabama Sta. Rpt. 1937, pp. 16-20, 23, 24*).—Results are briefly reported for the following studies: The cost of beef production in eastern Alabama, peanut hay as a roughage for fattening steers and for wintering breeding cows, kudzu as a grazing crop for beef cattle and for hogs, and the transmission of factors related to the economical production of swine, all by J. C. Grimes; the use of ice in curing pork on the farm, by W. E. Sewell; a comparison of dry rations for dogs, the comparative nutritive requirements of dogs and rats, both by C. J. Koehn; and the supplemental value of peanuts to the chick and laying ration, by G. J. Cottier and D. F. King.

[Livestock investigations in Iowa] (*Iowa Sta. Rpt. 1938, pts. 1, pp. 84-88, 91-96, 97, 99-101; 2, pp. 69-71*).—Brief progress results of studies (El. S. R., 79, p. 520) reported in part 1, by C. C. Culbertson, J. L. Lush, M. D. Helser, F. J. Beard, B. H. Thomas, J. A. Schulz, S. H. McNutt, P. M. Nelson, P. S. Shearer, A. B. Caine, and L. Yoder, include the evaluation of swine breeding stock by determining the growth, gains, ability to utilize feed, and carcass quality of the offspring; the relation of vitamin E to reproduction of swine and sheep; the adaptability of the rat for studying the chemical relationships between the food ingested and the softness of body fat; the influence of different amounts of soybeans and their products upon the quality of pork and keeping quality of lard; the influence of low temperatures upon beef and pork held in storage for different intervals; the factor present in linseed oil and linseed oil meal responsible for finish on fattening steers; factors involved in the production of colts; and the production of derivatives of sterols and their role in nutrition.

Reports of poultry investigations under the leadership of E. W. Henderson, H. L. Wilcke, Thomas, H. Giese, C. Murray, C. D. Lee, N. F. Waters, and B. Lowe include the biological value of different levels of meat scraps and milk combinations for egg production and the influence of rations and management on egg quality and size, a comparison of avian embryonic growth rates as measured by nitrogen and ash content, the air requirements of poultry, the effect of levels and sources of proteins and inorganic elements in the ration on slipped tendon in chicks and poults, the biological efficiency of several protein fractions for numbers, size, and quality of eggs, the relation of the viscosity index to the hatchability of eggs, the tolerance of poultry for fat in the ration, the comparative efficiency of some protein supplements for growth and nitrogen retention of chicks, factors in oats which affect growth and feathering in fowls, and the effect of the ration and the fattening period upon gains and quality of market poultry.

In part 2, results are briefly noted on a comparison of long corn fodder, cut fodder, ground fodder, and corn silage for finishing steer calves in dry lot, by Culbertson, Shearer, Helser, Beard, and Thomas.

[Experiments with livestock by the Cornell Station] ([*New York*] *Cornell Sta. Rpt.* 1938, pp. 87-89, 90, 91, 95-99, 144, 145, 147, 148, 149, 150).—Reports of investigations with farm animals, by F. B. Morrison, J. P. Willman, E. L. Worthen, R. W. Pease, N. F. Smith, G. M. Cairns, V. H. Melass, P. Olafson, S. A. Asdell, R. B. Hinman, J. I. Miller, C. M. McCay, L. A. Maynard, R. A. Rasmussen, G. K. Davis, G. Sperling, L. Barnes, G. Ellis, G. Kimball, M. J. Babcock, and K. Mills, include large-scale sheep and wool production in New York, distillers' corn dried grains and brewers' dried grains for fattening lambs, the relation of feeding and management to the cause of the stiff-lamb disease, a comparison of forage crops as temporary pastures for lambs, a comparison of various protein, vitamin, and mixed supplements for pigs, rations and methods of feeding the lactating sow and her suckling pigs, the causes and prevention of birth mortality in pigs, the protein requirements of fattening yearling cattle, the nutritive value of the proteins in common protein-rich supplements and in typical legume and nonlegume rations, the requirements of Herbivora for the B group of vitamins, cod-liver oil injury in Herbivora, and the prolongation of productive life of animals.

Reports of poultry investigations, by L. C. Norris, G. F. Heuser, G. O. Hall, and A. L. Romanoff, include the requirements of poultry for the components of the vitamin G complex, protein concentrates for laying hens, the role of manganese in poultry nutrition, the value of yeast in poultry feeding, the effect of controlled temperature and different light rays on breeding birds, and the early detection of infertile eggs.

[Livestock investigations in Oklahoma] (*Oklahoma Sta. [Bien.] Rpt.* 1937-38, pp. 39-62, 63, 64, 152-160, 163-175, 177-180, figs. 6).—Results are briefly reported for the following studies: The relative value of cattle fattening rations containing different proportions of molasses and corn, the comparative value of corn-molasses v. oat-molasses rations for fattening cattle, a comparison of prairie hay, alfalfa, cottonseed hulls, and sorghum silage as roughages for wintering steer calves, and tests to determine the cheapest available sources of concentrates for wintering steers, all by W. L. Blizzard; the value of creep feeding in the production of early calves and heifers, by B. R. Taylor; the value of mineralized yeast for fattening pigs, and the value of molasses in combination with oats and corn for hogs, both by C. P. Thompson; the effect of protein levels on prenatal development of pigs, by Thompson and J. C. Hillier; the effect of inbreeding swine, by W. A. Craft and O. S. Willham; corn v. cottonseed meal and prairie hay v. alfalfa for fattening lambs, the economic returns for feeding grain to lambs on wheat pasture, the value of flushing breeding ewes, the returns secured from creep-feeding lambs, the effect of age of sheep on wool characters, and the effect of molasses in the sheep ration on digestibility of fats, all by H. M. Briggs; good management as a means of correcting stiff joint ailment of lambs, by Briggs, V. G. Heller, and L. H. Moe; and methods of curing home-killed pork and lamb, by J. A. Beall.

From poultry investigations results are noted on the effect of cottonseed meal in the ration on egg quality, poor sanitation as related to egg quality, and the value of evaporation-type egg cooler, all by R. B. Thompson and C. A. Roberts, the optimum crude fiber level for chickens and turkeys, and the effect of all-night lighting of the flock during winter months, both by R. Penquite; the effect of protein level on egg production and size, growth rate, and viability of chicks, by Penquite and T. T. Milby; methods of preventing slipped tendon in chicks, by Penquite and Heller; the relation of body conformation (live bird measurements) to market quality of chicks and turkeys, by Penquite and R. G. Jaap; breed variations in body form, by Jaap; optimum protein

levels for turkeys, the value of dried grasshoppers for poult, the range requirements of turkeys, and the value of all-night lighting for breeding turkeys, all by Milby; and a State-wide turkey grading program (coop. U. S. D. A.), by Roberts, R. B. Thompson, A. W. Jacob, H. G. Ware, and L. Morris.

[Livestock investigations in Pennsylvania] (*Pennsylvania Sta. Bul.* 367 (1938), pp. 7, 24-29, 31, 54-57, figs. 2).—Studies for which results are briefly reported include the relative efficiency of gains in Good, Medium, and Common feeder steers and a comparison of corn silage, alfalfa-molasses silage, and alfalfa hay as roughages for fattening steers, by F. L. Bentley and P. T. Ziegler; optimum levels of soybean oil meal for lambs and hothouse lamb production, by T. B. Keith and W. L. Henning; factors affecting the quality of Merino wool, by Henning and R. C. Miller; protein requirements of pigs, by Keith, M. A. McCarty, and Miller; the curing of frozen hams, by Miller and Ziegler; causes of phosphorus deficiency in cattle, by E. B. Forbes and S. R. Johnson; the effect of deficiencies in essential nutrients, by Forbes; the specific dynamic action of proteins, by M. Kriss; the manganese requirements of the rat, by R. A. Dutcher and N. B. Guerrant; and determinations by A. K. Anderson of the allantoin content of bovine blood.

From poultry investigations results are reported on the value of dried skim milk for chickens and the vitamin A requirements of poultry, by H. C. Knandel and R. V. Boucher; factors affecting sexual development of chickens, by E. W. Callenbach and J. E. Nicholas; factors affecting the quality of eggs, by D. R. Marble, Nicholas, and Knandel; the comparative nutritive value of firm and watery egg albumin, by Dutcher and Guerrant; fishy flavor and odor in turkeys, by R. B. Murphy, Boucher, and Knandel; and the breeding of chickens for livability, by Marble.

[Experiments with livestock in South Carolina] (*South Carolina Sta. Rpt.* 1938, pp. 75, 76, 77, 83-85, 95-98, 99).—Results are briefly presented for the following lines of investigation, by L. V. Starkey, E. G. Godbey, E. D. Kyzer, R. L. Jones, and J. H. Mitchell: A comparison of silage v. cottonseed hulls in the winter ration of beef cows, the use of a reserved permanent pasture for shortening the winter feeding period of beef cows, cottonseed meal and hulls v. corn and alfalfa hay for fattening steers, creep feeding v. noncreep feeding of beef calves, sorghum silage v. rye pasture for wintering stocker steers, the effect of phosphorus fertilizer treatments on the beef-producing capacities of Coastal Plains pastures, a comparison of crossbred v. purebred pigs from double litters, a comparison of protein supplements for fattening hogs on rye forage, and the use of floored pens v. large dry lots in the feeding of fattening hogs.

Reports of poultry investigations, by C. L. Morgan and R. C. Ringrose, include the effect of cottonseed meal and cottonseed oil in laying rations on the hatchability of eggs, the value of whole oats in laying rations, and the influence of different components of the ration upon cannibalism in poultry.

[Animal husbandry investigations in Texas]. (Partly coop. U. S. D. A.). (*Texas Sta. Rpt.* 1937, pp. 17-20, 24-26, 27, 28, 29, 44-57, 132-134, 137-140, 161, 173, 182, 227-229, 234, 235, 245-249, 257, 258, 262, 263, 264, 265, 270).—Progress results (E. S. R., 79, p. 85) of beef cattle investigations, by J. M. and J. H. Jones, R. E. Dickson, H. Schmidt, T. W. Workman, G. S. Fraps, A. R. Kemmerer, J. K. Riggs, P. R. Johnson, R. A. Hall, J. A. Bayles, E. K. Crouch, E. H. Hansel, E. B. Reynolds, R. H. Stansel, W. H. Black, L. H. Tash, W. H. Dameron, O. L. Carpenter, F. E. Keating, and S. Cover, include the vitamin A and carotene requirements for growing and fattening cattle, the mineral requirements of cattle, the value of dried citrus peel and pulp meal for fattening cattle, the maximum use of roughages and optimum levels of hegarl fodder and alfalfa

hay in fattening rations, the mineral and protein deficiencies of pastures in the east Texas forest region, the ineffectiveness of cottonseed cake and prairie hay for wintering beef heifers, the carrying capacity of unimproved and improved pastures, the effect of mineral deficiencies on range beef cattle production, the efficiency of feed utilization by feeder calves fed singly and in groups when full-fed and when fed limited rations, and the effect of additional fat (cottonseed oil) in cottonseed meal-silage rations for steers.

Studies with sheep and goats, by J. M. and J. H. Jones, Dickson, Schmidt, Fraps, Kemmerer, Dameron, Carpenter, Cover, A. K. Mackey, C. E. Murphey, S. P. Davis, B. L. Warwick, and D. A. Spencer, include the vitamin A requirements of sheep and goats, the effectiveness of feeding cottonseed meal and mixtures of cottonseed meal, salt, and lime in preventing bitterweed trouble and promoting growth of range sheep, the effect of degree of fatness on tenderness and flavor in lamb, the relation of age of animals to fineness of wool and mohair, determining the grades and shrinkage of wool and mohair, the adaptability of Corriedale sheep to southwest Texas conditions, and the value of crutching or tagging bred ewes.

The results of swine studies are noted on the vitamin A requirements of pigs, by F. Hale and Fraps; methods of feeding brood sows, Sudan grass and oat pasture for fattening hogs, the calcium requirements for growing and fattening pigs receiving cottonseed meal, all by Hale; storing sliced cured bacon in different oils, by Cover and Hale; and a comparison of methods for storing home-cured hams and bacon, by Hale, R. Snyder, and D. L. Jones.

The palatability of the grain of various pure and crossbred strains of sorghums was studied by J. R. Quinby and J. C. Stephens, and the hardness of cottonseed cake by F. D. Fuller and J. Sullivan.

Poultry studies, by E. M. Sherwood, J. R. Couch, and Fraps, gave information on factors involved in the slipped tendon disease of chicks, and the quantitative requirements of the chick for vitamin A, vitamin D, and calcium and phosphorus.

Chemical studies, by Fraps, Kemmerer, E. C. Carlyle, and J. F. Fudge, relate to the productive energy values of animal feeds and human foods, the vitamin content of commercial feeds, and the iodine content of Texas feeds and waters.

[*Animal nutrition in Wisconsin*] (*Wisconsin Sta. Bul. 442 (1938), pp. 83-92, 93-96, figs. 2*).—Studies for which results are reported include the cobalt requirement of animals, by E. J. Underwood; the fluorine content of the bones of young calves, by R. J. Evans and P. H. Phillips; the effect of heat on the growth-promoting power of edestin, by H. A. Waisman and C. A. Elvehjem; the ability of calves to utilize simple nitrogen compounds as a substitute for proteins, by E. B. Hart, G. Bohstedt, and M. I. Wegner; the composition, keeping quality, and feeding value of legume silages prepared with preservatives and with additions of mineral acids, molasses, or whey, by W. H. Peterson et al.; the effect of feeding alfalfa silage on the vitamin A content of milk, by Peterson, A. C. Dornbush, and F. R. Olson; properties and behavior of the "grass juice factor," by G. O. Kohler, S. B. Randle, Elvehjem, and Hart; the role of manganese and rice bran in preventing slipped tendon in poultry, by A. C. Wiese, B. C. Johnson, Elvehjem, Hart, and J. G. Halpin; the ineffectiveness of nicotinic acid as a cure for chick pellagra, by Elvehjem, Waisman, O. Mickelson, and D. W. Woolley; chondroitin as a preventive of gizzard lesions in chicks, by H. R. Bird, J. J. Oleson, et al.; and histopathological changes occurring in curled toe paralysis, slipped tendon, and vitamin B₆ deficiency of chicks, by R. W. Engel and Phillips.

Radioactive phosphorus as an indicator of phospholipid metabolism, I-IV. (Univ. Calif.). (*Jour. Biol. Chem.*, 122 (1937), No. 1, pp. 169-182, figs. 6; 123 (1938), No. 2, pp. 587-593, figs. 3; 124 (1938), No. 3, pp. 795-802; 126 (1938), No. 2, pp. 493-500, figs. 3).—Four reports on this study are noted.

I. The rate of formation and destruction of phospholipids in the fasting rat, I. Perlman, S. Ruben, and I. L. Chaikoff.—A method for the preparation of the radioactive isotope of phosphorus is briefly described. In two series of rat feeding trials in which disodium phosphate (radioactive) was incorporated in the diet, the percentage of the labeled phospholipid present in the gastrointestinal tract, liver, kidneys, carcass, and the whole body at various intervals after feeding was determined. The labeled phospholipid appeared in all tissues examined.

II. The rôle of the stomach, small intestine, and large intestine in phospholipid metabolism in the presence and absence of ingested fat, B. A. Fries, S. Ruben, I. Perlman, and I. L. Chaikoff.—Rats were fed diets containing the radioactive phosphorus, and a comparison was made of the phospholipid turn-over in various parts of the gastrointestinal tract. Either in the absence or presence of ingested fat, the major part of the phospholipid turn-over occurred in the small intestines, the stomach and large intestines having but a small part in this type of metabolism. Removal of both gastrointestinal tract and kidneys which were very active in phospholipid metabolism had little effect on the phospholipid turn-over in the liver.

III. The conversion of phosphate to lipid phosphorus by the tissues of the laying and non-laying bird, C. Entenman, S. Ruben, I. Perlman, F. W. Lorenz, and I. L. Chaikoff.—Laying and nonlaying (molting) White Leghorn hens were sacrificed at 6 or 12 hr. after receiving injections of radioactive phosphorus, and the percentage recovery of this substance in different body tissues was determined. About 5 percent of the labeled phosphorus administered appeared as phospholipids in the whole body, with about 2 percent contained in the bone, muscle, and blood. Per 100 gm. of tissue the greatest amounts of this substance were present in the kidneys, livers, and small intestines. The blood, oviduct, and ovary of the laying hens showed greater phospholipid activity than those of nonlaying birds. The labeled phospholipid was present in egg yolks 6 hr. after administration and present in greater quantities after 12 hr. The amount deposited in yolks followed the increase in yolk size until a yolk weight of 5.8 gm. was reached.

IV. The phospholipid metabolism of the brain, G. W. Changus, I. L. Chaikoff, and S. Ruben.—Trials with rats showed that following the ingestion of labeled phosphate the radioactive phospholipid was deposited in the brain at a much slower rate than the liver, kidneys, or small intestines. Progressive increase in the content of this phospholipid in the brain was observed as long as 200 hr. after administration. After the maximum amount of this phospholipid had been deposited in the brain its loss occurred at a very slow rate, its presence being detected as long as 4 weeks after being fed. The rate of formation of brain phospholipid was identical in the fed and fasted rats, larger amounts being stored in the young than in the adult brain.

Studies on the relative efficiency of vitamin D from several sources, I, II, J. T. CORRELL and E. C. WISE (*Jour. Biol. Chem.*, 126 (1938), No. 2, pp. 573-588, fig. 1).—The results of two studies are reported, dealing respectively with the influence of vitamin D of different origins on (1) bone ash and body weight and (2) on the serum phosphatase of the chicken.

Comparative tests in which chick rations were supplied with different levels of vitamin D from a number of commercial samples of tuna-liver oil and cod-liver

oil indicated that, rat unit for rat unit, the tuna-liver oil was only from 40 to 60 percent as effective as the cod-liver oil for chicks as measured by bone ash content. The former sources of vitamin D were also much less efficient than the latter in promoting growth of chicks during the first few months of life.

The serum phosphatase concentration in 2-day-old chicks was found to be about 80 Bodansky units per 100 cc. When adequate amounts of vitamin D were supplied the concentration of serum phosphatase rapidly declined, approaching a level of 20 units per 100 cc., but in the absence of vitamin D the concentration increased to over 200 units per 100 cc. in highly rachitic chicks. On a rat-unit basis supplements of cod-liver oil proved more efficient than irradiated ergosterol or the tuna-liver oils in reducing the phosphatase activity in the serum of growing chicks.

Further studies on dietary factors associated with nutritional muscle dystrophy, S. MORGULIS, V. M. WILDER, and S. H. EPPSTEIN. (Univ. Nebr.). (*Jour. Nutr.*, 16 (1938), No. 3, pp. 219-227, figs. 5).—Previous findings (E. S. R., 76, p. 882) indicating that two or more nutritive factors are involved in the prevention or cure of muscular dystrophy in rabbits were further confirmed in this study. All the effective factors were found to be present in acetone extracts of wheat germ oil and to a lesser extent in cottonseed oil. Also the feeding of green lettuce in large amounts as a supplement to the basal diet cured dystrophic rabbits. When whole wheat germ was fractionated into its fat-soluble and water-soluble components neither fraction alone prevented or cured dystrophy, but when the two extracts were fed together severely dystrophic rabbits quickly recovered and grew vigorously. Further tests indicated that the fat-soluble fraction is closely associated, or perhaps identical, with vitamin E. The water-soluble fraction evidently belongs to the vitamin B complex since it is supplied by lettuce, yeast, and a variety of vitamin B concentrates.

Commercial feeding stuffs, L. S. WALKER, E. F. BOYCE, and L. E. DAVIS (*Vermont Sta. Bul.* 443 (1938), pp. 48).—This is the usual report of the analyses for protein, fat, and fiber of 1,694 samples of feeding stuffs collected for official inspection during April 1938 (E. S. R., 79, p. 669).

The nutritive value of distillers' by-products, A. D. D'ESCOLE, W. B. ESSELEN, JR., and C. R. FELLERS. (Mass. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 1, pp. 89-95).—Distillers' grains and concentrated distillers' slop were assayed with reference to vitamins A, B₁, B₂ (riboflavin), C, and D and protein quality. All assays were with rats except for B₂ and protein quality, in which cases both rat and chick methods were used. The grain and slop, respectively, contained 2 and 5.4 Sherman units of B₁, 2.4 and 3 Sherman units of B₂, and 1.4 and 15.6 Cornell units of B₂ per gram. Both materials were practically devoid of vitamin A activity and contained only small amounts of antirachitic substance. The slop contained a small amount of a vitamin C-like material. The proteins of these products were relatively poor in growth-promoting properties. It is suggested that the addition of from 10 to 15 percent of these products to poultry rations should provide an economical and satisfactory source of vitamin B₁ and riboflavin and would also supply desirable minerals.

Oat mill feed: Its usefulness and value in livestock rations, A. W. LATHROP and G. BOHSTEDT, in collab. with A. H. WALKER and H. J. DEOBALD (*Wisconsin Sta. Res. Bul.* 135 (1938), pp. 128, figs. 20).—The results of extensive investigations dealing with the composition and digestibility of oat mill feed and its usefulness and value for horses, swine, lambs, fattening cattle, and dairy cows and heifers, are summarized.

This product contained an average of 5.5 percent crude protein, 27.9 crude fiber, and 6.4 ash. It contained only small amounts of calcium and phosphorus

and vitamins A and D. Digestion trials with horses, cattle, and sheep indicated total digestible nutrient values of 35.2, 33.8, and 37.9 percent, respectively (average 35.6), while trials with swine gave a value of only 22.4. Horses at light or medium hard work were satisfactorily maintained for nearly 6 yr. on oat mill feed alone, and in short trials this product had approximately the same value as timothy hay. Respiratory and digestive disturbances were occasionally encountered under certain conditions of feeding. When oat mill feed replaced from 16 to 24 percent corn or hominy feed in swine fattening rations, the rate of gain and quality of finish were practically equal to those of the check lots. Up to 30 percent oat mill feed could be included in the ration of pigs on rape pasture. The feed replacement value of the oat mill feed generally ranged from 25 to 48 percent of the value of ground corn. Up to 40 percent oat mill feed in the ration of bred sows on pasture gave good results. In practical bred sow rations the values ranged from 29 to 49 percent that of ground corn. In trials with lambs, in which the oat mill feed replaced 30 percent of corn or a part or all of the alfalfa hay, its replacement value was from 26 to 45 percent of corn and 60 percent that of alfalfa. When oat mill feed replaced from 15 to 30 percent of corn or hominy feed in cattle fattening rations, a good quality roughage was provided, satisfactory gains and finish were obtained, and its replacement value was from 30 to 40 percent that of corn. The oat mill feed failed to maintain the health of beef cattle when fed as a sole roughage. When fed to dairy cows in combination with silage, oat mill feed was 96 and 73 percent as valuable as timothy and alfalfa, respectively, and when fed as 40 percent of the concentrate ration was 50 and 65 percent as valuable as corn and wheat bran, respectively. It was worth 35 percent as much as corn when fed with silage and protein concentrates to dairy heifers.

Oat mill feed in livestock rations, G. BOHSTEDT and A. W. LATHROP, in collab. with A. H. WALKER and H. J. DEOBALD (*Wisconsin Sta. Bul.* 441 (1938), pp. 55, figs. 10).—A popular and less detailed report of the above research.

[The selenium content of Maine feeding stuffs], E. R. TOBEY and B. E. PLUMMER, JR. (*Maine Sta. Bul.* 391 (1938), pp. 257, 258).—Of the numerous samples of feeding stuffs analyzed, many gave entirely negative results for selenium and none contained in excess of 2 p. p. m. of this element.

Nutritive value of pasture, XII–XIV (*Jour. Agr. Sci. [England]*, 28 (1938), No. 4, pp. 581–603).—The following reports were made on this series of studies (E. S. R., 73, p. 665):

XII. *The influence of cutting at monthly intervals over nine seasons on the quality and productivity of a heavy-land pasture*, H. E. Woodman and R. E. Evans.—A series of variously fertilized permanent pasture plats, located on heavy clay soil and each receiving an annual fall application of farmyard manure, was included in this study. Monthly clipping of these pastures over a period of 9 yr. did not result in any deterioration of productivity or a decline in quality of the grass, as judged by both chemical and botanical composition.

XIII. *An inquiry into the residual effects of the intensive use of sulphate of ammonia on pastures*, H. E. Woodman and R. E. Evans.—Certain plats in the above-described experiment received periodic applications of sulfate of ammonia for the first 5 yr. of the test, after which this treatment was discontinued and its residual effect determined in the following years. It appeared that the artificial stimulation of growth over a period of years by the use of sulfate of ammonia had reduced the inherent vigor of the grasses so that when the stimulus was discontinued they were unable to grow as rapidly as grasses which had not received this stimulation. These plats showed complete recovery from this effect 3 yr. after such fertilization was discontinued.

XIV. *The influence on yield and composition of a single heavy dressing of sulphate of ammonia compared with that of periodic small dressings throughout the season*, H. E. Woodman, R. E. Evans, and P. M. Oosthuizen.—Experimental evidence was obtained to indicate that the application of sulfate of ammonia in three or more periodic small dressings throughout the season offered distinct advantages over a single heavy application in the early spring. The former method eliminated the possibility of scorching, which often resulted from the latter practice, and maintained a more uniform supply of grass throughout the season.

The comparative values for eight protein supplements in winter rations for stock cattle, C. W. McCAMPBELL and L. C. AICHER (*Kansas Sta., Fort Hays Substa., Beef Cattle Invest., 1937-38, pp. 8*).—Continuing these investigations (E. S. R., 78, p. 836), results are reported for the 1937-38 trials with calves and with yearlings, and the results of three trials with calves are summarized. This year's results confirm previous findings in that lots of both calves and yearlings receiving 3 lb. of wheat bran per head daily as a supplement to sorgo silage made the most rapid and most economical gains, closely followed by the lots receiving 4 lb. of alfalfa hay. These lots exceeded any of the groups receiving 1 lb. per head daily of a high protein concentrate. Of the six protein concentrates compared, corn gluten meal gave most rapid and economical gains in calves, both on the basis of the 1937-38 trial and the 3-yr. average, closely followed by the cottonseed meal group. With yearlings there was little difference in the gains produced by the different protein supplements, except in the case of peanut meal which produced considerably less gain.

The Mandan grazing trial, J. H. SHEPHERD (*North Dakota Sta. Bimo. Bul., 1 (1939), No. 3, pp. 7-9*).—This article briefly reviews the results of 24 consecutive years of grazing trials with 2-year-old or yearling steers on North Dakota range pastures to determine the effect of rate of stocking the range on the daily gains of cattle, the quality of beef produced, and the quality and botanical composition of the pasture flora.

Nutritional studies with cattle on a grassland-type range in Arizona, E. B. STANLEY (*Arizona Sta. Tech. Bul. 79 (1938), pp. 127-164, figs. 10*).—The investigations summarized in this bulletin extended from 1933 to 1937. Four range areas, each containing approximately 380 acres and cornering at a watering place, were used. During the first year each area was stocked with 18 cows and 17 calves, and in subsequent years 20 cows and their calves were carried on each. Throughout the trials the cows were rotated at regular intervals to minimize the effect of any differences in the amount or type of available forage. Earlier reports have dealt with the vitamin A content (E. S. R., 79, p. 230) and the chemical composition (E. S. R., 80, p. 83) of these range grasses.

The nutritive qualities of this grassland range were found adequate for the yearlong maintenance of these cattle breeding units. Two years' results indicated that calcium and phosphorus supplements were in no way beneficial. Five years' results gave evidence that the feeding of cottonseed cake as a winter supplement had relatively little effect on either the birth weight or weaning weight of the calves and was considered impractical except as an emergency feed. The average salt consumption of cows was 1.68 oz. per head daily, ranging from over 3 oz. in winter to less than 1 oz. in summer. The water consumption varied directly with air temperature and evaporation, but averaged 6.3 gal. per head daily. Preliminary studies indicated that creep feeding range calves was not a feasible practice. A study of the relation of birth weight and weaning weight of calves indicated that a 10-lb. weight advantage at birth was indicative of a 46-lb. advantage at 200 days of age. Substantial progress was attained in increasing

the average size of cows and calves during the course of this investigation, attributable to the use of good type bulls and improved management practices.

An apparatus and technique for measuring the respiratory exchange of fed sheep over periods of forty-eight hours, E. W. L. LINES (*Jour. Agr. Sci. [England]*, 28 (1938), No. 4, pp. 663-678, figs. 4).—This report from the University of Adelaide presents a full description and constructional details for a respiration chamber, gas sampling and collecting devices, and modifications in the structure and operation of the Haldane-Carpenter gas analysis apparatus. This apparatus automatically compensates for diurnal changes in temperature and humidity and maintains a constant rate of ventilation. Methods for computing the energy metabolism and respiratory quotient from the gaseous exchange and methane production are fully described. Measurement of the gaseous exchange of sheep with this equipment gave good agreement with the energy absorbed from a maintenance diet.

Identification and measurement of the combustible gases that occur in the gaseous metabolic products of sheep, J. W. H. LUGG (*Jour. Agr. Sci. [England]*, 28 (1938), No. 4, pp. 688-694, fig. 1).—This further report from the above research institution describes an apparatus for the estimation of combustible gases in the gaseous metabolic products of sheep. Preliminary trials with sheep gave an average ratio of hydrogen to carbon atoms in the combustible gases of 1:3.999, indicating that the gas is extremely pure methane. The heat of combustion of the methane produced was about one-eighth of the difference between the heat of combustion of the intake and that of the feces plus urine, which is in reasonable agreement with earlier published results for ruminants.

Relative efficiency for growing lambs of the protein in rations containing alfalfa hay, timothy hay, and combinations of the two hays, J. I. MILLER and F. B. MORRISON. ([N. Y.] Cornell Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 2, pp. 149-155).—A series of nitrogen-balance experiments was conducted with growing lambs to determine the digestibility and utilization of the following rations: (1) Corn and alfalfa hay, (2) corn and a mixture of alfalfa and timothy 2:1, (3) corn, soybean oil meal, and a mixture of alfalfa and timothy 1:2 and (4) corn, soybean oil meal, and timothy. The roughages comprised 50 percent by weight of the ration, and the other ingredients were so adjusted as to provide the same energy, mineral, and protein (10 percent) intake levels in each case. The average percentage of total protein stored was 17, 20.2, 23.7, and 21.3, and the estimated biological value of the protein was 59, 60, 64, and 62 for rations 1, 2, 3, and 4, respectively. The only statistically significant differences in values existed between rations 1 and 3. Apparently a ration of corn and timothy, when properly supplemented, furnished protein of as high efficiency for lambs as rations of corn and alfalfa.

Overeating by fattening lambs is serious problem of feeding industry in Colorado, I. E. NEWSOM (*Colo. Farm Bul. [Colorado Sta.]*, 1 (1939), No. 1, pp. 4, 5).—The prevalence of disorders and death of grain-fed lambs due to overeating is discussed. The need for introducing more roughages into the fattening ration and carefully regulating the grain intake in order to prevent such disorders is stressed.

A study of the development of the characters of the fleece during growth in the different regions of the body, L. F. THOMASSET (*Jour. Agr. Sci. [England]*, 28 (1938), No. 4, pp. 523-540, pls. 4, figs. 5).—In a study of twin lambs of a Suffolk × Suffolk (Border Leicester × Cheviot) cross, the fleece of the different body regions developed in the following order—shoulder, leg, belly, and tail. Color of fibers, the amount of medullated fibers, fineness of fibers, and uniformity of fiber size were considered. Any tendency toward wool improve-

ment within a breed was first expressed by changes in the earliest developing region and last in the latest developing region. An improved animal is considered as one in which the latest developing part of the fleece has the least possible number of undesirable fibers at the earliest possible age. It appeared that examination of the fleeces of lambs, particularly in the late-developing areas, would reveal defects and give some idea of the genetic constitution which would be concealed in an adult animal.

A normal growth curve for swine, N. R. ITTNER and E. H. HUGHES. (Univ. Calif.). (*Jour. Heredity*, 29 (1938), No. 10, pp. 385, 386, fig. 1).—A growth curve based on the average rate of growth of 457 pigs from 3.2 lb. at birth to 182.5 lb. at 196 days of age is presented. The curve showed a gradual acceleration until the pigs were about 6 mo. of age (160 lb. in weight), after which the rate of gain began to decline.

Bibliography of poultry publications (U. S. Dept. Agr., 1938, pp. [1]+76).—This compilation, by the Departmental Poultry Committee, of references on poultry subjects includes Department publications, popular and scientific articles, and published addresses by employees of the Department.

Variability of body temperature in the normal chick, W. F. LAMOREUX and F. B. HURT. (Cornell Univ.). (*Poultry Sci.*, 18 (1939), No. 1, pp. 70-75, figs. 3).—A pronounced rise occurred in the body temperature of chicks during the first week after hatching, particularly during the first 4 days, although no significant differences were noted between average temperatures at 4 and 5 days of age. White Leghorns had a significantly higher body temperature than Rhode Island Reds at 7 to 10 days of age. No consistent relationships were found between temperature and sex or temperature and body weight. Diurnal variations, temperature gradient, and differences in the ability of the attendants to record temperatures were other major causes of variation. The necessity of carefully standardized technics for recording temperature and caution in comparing results from the different experiments are stressed.

The utilization of food elements by growing chicks.—VI, The influence of the protein level of the ration on the growth of chicks, C. W. ACKERSON, M. J. BLISH, and F. E. MUSSEHL (*Nebraska Sta. Res. Bul.* 108 (1939), pp. 12, figs. 2).—Continuing this series of studies (E. S. R., 79, p. 525), two rations containing 16 and 22 percent of protein, respectively, were fed to newly hatched chicks in two series of feeding trials. The chicks fed the 22 percent protein ration made greater gains on the same dry matter intake over the same period of time and showed a higher percentage of nitrogen in the gain than those receiving the 16 percent ration. However, chicks on the 16 percent level showed a higher ratio of gain in weight to nitrogen fed and retained a higher percentage of nitrogen fed. Only slight differences occurred in the percentage retention of calcium and phosphorus. The dilution of the 22 percent protein basal ration with 30 percent of starch to give a 16 percent ration resulted in uniform and definite evidence of depraved appetite, including feather picking and coprophagy, and also gave poor feathering.

Comparative values of various protein feeds for growing chicks, R. M. SHERWOOD and J. R. COUCH (*Texas Sta. Bul.* 569 (1939), pp. 27).—Five experiments, each with six lots of chicks, were conducted to determine the relative value of various combinations of protein-rich feeds, as measured by average live weight gains, feed requirement per unit of gain, and percentage mortality. Protein concentrates included sardine meal, dried skim milk, meat and bone scraps, cottonseed meal, and soybean oil meal, three of these feeds being used in combination in each of the nine rations tested. In practically all cases, rations containing sardine meal, regardless of other constituents, produced larger gains

and required less feed per unit of gain than rations not containing this ingredient. However, the sardine meal rations resulted in slightly higher mortality than when this ingredient was omitted, except in the case of the sardine meal-skim milk powder-soybean oil meal combination. Excessive mortality resulted when sardine meal was fed in combination with meat and bone scraps and soybean oil meal, but this high mortality did not occur when cottonseed meal replaced soybean oil meal in the mixture. In practically all cases, soybean oil meal and cottonseed could be used interchangeably and also dried skim milk and meat and bone scraps could be interchanged without appreciably affecting results. It appeared that, with the exception of the sardine meal-meat and bone scraps-soybean oil meal mixture, any of the combinations tested could be recommended to give satisfactory results, and that availability and cost per hundredweight should determine which one to use.

Vitamin "A" requirements of growing chicks: A review of experimental work, A. E. TEPPER and R. C. DUBBIN (*New Hampshire Sta. Bul. 310 (1938), pp. 23, figs. 6*).—Experimental results obtained over a 6-yr. period are summarized. The various objectives in this series of investigations included the effect of various levels of cod-liver oil for growing chicks, the effect of changing chicks from an adequate vitamin A ration to a deficient vitamin A ration at an early age, the effect of increasing cod-liver oil levels as chicks advanced in age, the relative value of the New England College Conference ration with and without cod-liver oil, the vitamin A potency of sardine oil and the relative efficiency of sardine and cod-liver oils, and the optimum number of vitamin A units required by growing chicks to 6 weeks of age.

The chicks showed a relatively high requirement for vitamin A for rapid growth and normal storage, amounting to approximately 135 International Units per 100 gm. of feed during the first 5 weeks and, thereafter, increasing to approximately 400 I. U. per 100 gm. of feed. When chicks were changed from a vitamin A-adequate to a deficient diet at 4 or 8 weeks of age, the stored vitamin A was not sufficient to meet their requirements for more than 2 weeks of deficiency feeding. Kidney injury and the presence of urinary crystals in the feces and scrapings from the large intestine accompanied vitaminosis A. An increased vitamin A consumption increased feed consumption, but too high a content of cod-liver oil in the feed tended to decrease livability of the chicks. Adding $\frac{1}{2}$ or 1 percent of either cod-liver oil or sardine oil to a vitamin A-deficient basal diet prevented the occurrence of vitaminosis A, with the cod-liver oil groups showing somewhat more rapid growth. Increasing the level of vitamin A intake beyond that supplied by 1 percent of good cod-liver oil was not warranted. The New England College Conference ration contained sufficient vitamin A to prevent ophthalmia and to support normal growth without additional vitamin A supplement.

Effectiveness of chondroitin in preventing gizzard erosion in chicks, H. R. BRID, J. J. OLESON, O. A. ELVEHJEM, and E. B. HART. (*Wis. Expt. Sta.*). (*Jour. Biol. Chem.*, 126 (1938), No. 2, pp. 671-678).—This is a more detailed report of research previously noted (*E. S. R.*, 80, p. 242).

The effect of riboflavin on the incidence of curled toe paralysis in chicks, E. L. R. STOKSTAD and P. D. V. MANNING (*Jour. Nutr.*, 16 (1938), No. 3, pp. 279-283).—In a series of experiments chicks were depleted for 2 weeks on a riboflavin-free diet and then fed graded amounts of riboflavin for 2- or 6-week test periods. Under these conditions chicks which were continued on a basal diet did not develop curled toe paralysis. With additions of suboptimal amounts of riboflavin this disorder developed in a high percentage of cases, but larger amounts of riboflavin, adequate to support normal growth, completely prevented it.

[Batteries for chicks, broilers, and laying hens] (*Oregon Sta. Circ. 130* (1938), p. 43).—Results of comparative tests are noted.

Effect of rearing environment on sexual development of fowls, E. W. CALLENBACH and J. E. NICHOLAS (*Pennsylvania Sta. Bul. 368* (1938), pp. [2]+9, figs. 4).—This report substantiates findings (E. S. R., 78, p. 385) that (1) the temperature and relative humidity of the brooder house had no measurable effect on the sexual development of pullets, (2) heavy grain consumption by immature pullets did not retard sexual development, and (3) the use of electricity for brooder heat, employing exposed, black-heat resistant coils, resulted in a slower rate of sexual maturity of pullets than comparable birds exposed to other sources of brooder heat.

Egg composition.—I, The effect of diet and storage on the chemical composition of eggs, R. REEDER. (Okla. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 1, pp. 19–25).—Six groups of White Leghorn pullets were fed diets of varying composition, three groups receiving all-mash rations containing 13, 16, and 25 percent protein, respectively, and the three remaining groups receiving mash and grain rations of varying composition and constituents. Composite samples of eggs from each group were analyzed while fresh and after storage periods of from 9 to 236 days. No significant differences were found in the composition of the fresh eggs produced on the different diets, and the changes in composition which occurred during storage were practically the same for all groups. In general, the moisture content of the yolks increased and that of the whites decreased during storage. The loss in total egg weight during storage was greatest in eggs produced on the high protein diet.

Turkey production, T. T. MILBY, R. G. JAAF, and R. B. THOMPSON (*Oklahoma Sta. Bul. 236* (1939), pp. 38, figs. 17).—A handbook on turkey production, including discussions of the selection and care of breeders, the construction of trap nests, incubation, brooding, the feeding and management of poults and growing turkeys, finishing, disease prevention and treatment, and marketing of turkeys.

Common laying rations without supplement may not be sufficient for breeder turkeys, H. S. WILGUS, JR. (*Colo. Farm Bul. [Colorado Sta.]*, 1 (1939), No. 1, pp. 16–18).—Preliminary results of a study to determine the vitamin G requirements of breeding turkeys necessary to give optimum hatchability of eggs indicated that an ordinary poultry laying ration without milk was deficient in this factor and that hatchability was markedly improved by adding 2.5 or 5 percent of dried whey to the ration. Poorer results were obtained in a second trial than in the first, indicating that rations may vary from season to season and that under certain conditions 5 percent of dried whey fails to provide an adequate level of vitamin G. Similar results were obtained with pens of layers in confinement and on range. Electric lights to provide a 14-hr. day proved effective in stimulating early egg production.

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle and dairy products in Iowa] (*Iowa Sta. Rpt. 1938, pt. 1, pp. 89–91, 124–134*).—Progress reports (E. S. R., 79, p. 528) of experiments with dairy cattle, by C. Y. Cannon, B. H. Thomas, D. L. Espe, and E. N. Hansen, include the relation of vitamin E to sterility in dairy cattle, the influence of the physical properties of milk on its rate of digestion in vivo, the value of corn sugar in the grain ration of dairy calves, and a comparison of roughages and the relation of roughages to grain in dairy cow rations.

Reports of progress are presented for the following studies with dairy products: Micro-organisms causing surface taint in butter, the germicidal properties of milk, the classification of the organisms important in dairy products, the development of butter cultures from mixtures of organisms, methods of preparing butter cultures for mail shipment, and the importance of acetylethylcarbinol and diacetyl in butter cultures, all by B. W. Hammer; the nitrogen metabolism of *Lactobacillus casei* cultures, and the fat and protein metabolism of *Penicillium roqueforti*, both by C. B. Lane and Hammer; the production of 2,3-butylene glycol in dairy products, by Hammer and C. H. Werkman; kinds of acids and their distribution in butter, and the effects of neutralizers on fat losses in buttermilk and on the quality of butter, both by E. W. Bird; sediment tests for cream and butter, by M. Mortensen and Bird; and the manufacture of a special-type Swiss cheese, and the standardization of Iowa dairy products, both by E. F. Goss and Mortensen.

[Investigations with dairy cattle and dairy products by the Cornell Station] ([*New York*] *Cornell Sta. Rpt.* 1938, pp. 86, 87, 90, 91-95, 103-106, 109).—Brief reports are presented for the following lines of investigation, by G. W. Salisbury, F. B. Morrison, E. S. Savage, E. S. Harrison, O. L. Lepard, R. B. Ace, W. C. Hurley, P. E. Newman, R. A. Rasmussen, R. Bogart, L. A. Maynard, C. M. McCay, K. E. Gardner, and H. Paul. The influence of the quality of the protein in the concentrate mixture on the production of dairy cows fed mixed hay and corn silage, the use of molasses or phosphoric acid in making silage from legumes and grasses, the effect of quality and variety of hay upon dairy heifers, the use of yeast in calf starters, the value of dried molasses-and-yeast byproduct for dairy calves, the ascorbic acid content of the milk of various species of animals, and studies on the physiology of lactation.

From investigations with dairy products, by P. F. Sharp, B. L. Herrington, D. B. Hand, V. N. Krukovsky, E. S. Guthrie, J. M. Sherman, C. N. Stark, and I. C. Gunsalus, results are noted for factors involved in the lipolytic activity of milk, factors affecting the vitamins in milk, various factors involved in the processing of milk, the utilization of milk sugar, factors influencing the physical state of milk fat, and numerous studies in the bacteriology of milk.

[Investigations with dairy cattle and dairy products in Oklahoma] (*Oklahoma Sta. [Bien.] Rpt.* 1937-38, pp. 7-14, 65-74, figs. 3).—Studies for which results are reported include the effect of continuous use of purebred sires on the average milk production of dairy herds, and the effect of methods of watering on growth of calves, both by P. C. McGilliard, E. Weaver, and A. H. Kuhlman; the vitamin A requirements of dairy cattle and the prevention of "cottonseed meal injury" by feeding adequate amounts of vitamin A, by Kuhlman, Weaver, and W. D. Gallup; the composition and nutritive value of mung bean silage, by Kuhlman, McGilliard, Weaver, and Gallup; and the effect of feeds on the quality of butterfat, the vitamin A potency of prairie hay, and the effect of season on the carotene content of hays, all by Gallup.

Studies with dairy products, by E. L. Fouts, J. I. Keith, W. V. Maddox, and Weaver, include the effect of cooling cream on the quality of butter, the use of oat flour in preventing rancidity in butter, copper as a causative factor of oxidized flavor in ice cream, factors causing sandiness in ice cream, and the common causes of off-flavors in milk.

[Dairy cattle investigations in Oregon] (*Oregon Sta. Circ.* 130 (1938), pp. 28, 29, figs. 3).—Preliminary findings regarding the effect of vitamin A, vitamin E, and phosphorus deficiencies on the reproduction of dairy cattle and the deficiencies of alfalfa hay as the sole roughage for milking cows are briefly discussed.

[Experiments with dairy cattle and dairy products in Pennsylvania] (*Pennsylvania Sta. Bul.* 367 (1938), pp 6, 10, 36-38, 39-43, figs. 2).—Results are briefly noted for the following studies: Vitamin D storage in calves, by R. A. Dutcher and N. B. Guerrant; the effect of fertilization on the returns secured from permanent pastures, by S. I. Bechdel and C. F. Noll (coop. U. S. D. A.); the carotene requirements of dairy calves, by Bechdel and Guerrant; methods of making alfalfa-molasses silage and its feeding value for heifers and for milking cows, by Bechdel and P. S. Williams; and the carotene content of dehydrated alfalfa and alfalfa-molasses silage, by Bechdel.

Studies with dairy products reported include methods of preventing flavor defects in milk and its products, by C. D. Dahle; the effects of the ration on milk color, by W. D. Swope; the comparative digestibility of soft-curd and hard-curd milks, low pressure homogenization of milk and cream, changes occurring in concentrated frozen milks, and the use of the phosphatase test for determining the efficiency of pasteurization, all by F. J. Doan; the bacteriological changes occurring during the curing of cheese, by Dahle, T. G. Anderson, and H. O. Triebold; and the detection of the coli-aerogenes group in milk, metabolic studies of the streptococci, and a comparison of various media for making bacteriological counts of milk, all by M. A. Farrell.

[Dairy cattle investigations in South Carolina] (*South Carolina Sta. Rpt.* 1938, pp. 77-81, fig. 1).—Brief progress reports are presented for the following studies, by J. P. LaMaster and G. H. Wise: The preservation and feeding value of various types of silage, the effects of changing milking cows from a silage ration to pasture and vice versa, a rotational system of grazing permanent grass pastures, and a comparison of the open-pail v. the nipple-pail method of feeding milk to calves.

[Investigations with dairy cattle and dairy products in Texas] (*Texas Sta. Rpt.* 1937, pp 135, 136, 137, 173).—Results are briefly noted on the quantitative requirements of vitamin A for dairy cattle, by O. C. Copeland, G. S. Fraps, and A. R. Kemmerer; cottonseed meal and hulls as a ration for milking cows, by Copeland; effective management practices for eradicating infectious abortion from dairy herds, by H. Schmidt, Copeland, and R. D. Turk; mineral requirements, by P. R. Johnson; and factors affecting the quality of southern short-cure Cheddar cheese, and methods of manufacture and other factors affecting the quality of butter, both by F. E. Hanson and C. N. Shepardson.

[Investigations with dairy products in Wisconsin] (*Wisconsin Sta. Bul.* 442 (1938), pp. 67-76, fig. 1).—Results are briefly reported for the following studies: The effect of time and temperature of incubation on Swiss cheese starters, by H. J. Peppler and W. C. Frazier; the bacteriology of Swiss cheese, by J. C. Garey, Frazier, and C. C. Schmiede; controlling the quality of brick cheese starters, by W. L. Langhus, P. R. Elliker, and W. V. Price; factors causing splitting of brick cheese, by F. E. Hanson, D. W. Spicer, and Price; a method of predicting acidity of brick cheese, by Price and Spicer; an improved method of measuring the salt content in butter and ways of improving uniformity of physical properties of butter, both by K. G. Weckel; factors involved in activated flavor in milk, by J. C. Flake, Weckel, and H. C. Jackson; the temperature of separation as related to lipase activity in cream, by J. C. Pfeffer et al.; constituents of milk involved in oxidized flavor development, by A. M. Swanson and H. H. Sommer; and improved methods for irradiation of milk, by H. H. Beck et al.

Urea as a protein substitute in the diet of young cattle, S. BARTLETT and A. G. COTTON (*Jour. Dairy Res.* [London], 9 (1938), No. 3, pp. 263-272, fig. 1).—In the experiment described, groups of dairy heifers ranging in age from 7

to 17 mo. were fed rations of normal protein content, low protein, and low protein supplemented with urea for 142-day experimental periods. The addition of 0.127 lb. of urea per animal daily resulted in a significantly greater average daily gain than for heifers on the unsupplemented low protein diet, indicating that the animals utilized the urea nitrogen in their metabolism. Animals receiving the same amount of supplemental nitrogen in the form of protein made slightly better growth than those receiving urea.

A study of the effect of feeding oils to dairy cows and of the value of the Latin square lay-out in animal experimentation, F. H. GARNER and H. G. SANDERS (*Jour. Agr. Sci. [England]*, 28 (1938), No. 4, pp. 541-555, figs. 2).—In these studies at the University of Cambridge a Latin square technic was employed, using 4 cows with 4 levels of fat feeding. In all, 14 experiments with unit periods of 5 days, 2 with 10-day periods, and 1 with a 20-day period, were conducted. Of the fats tested, palm oil, butter, lard, and possibly cottonseed oil increased the fat yield of the cows, chiefly by raising the butterfat content of the milk. Soybean, linseed, and whale oils were without effect, and cod-liver oil definitely decreased the fat content of the milk and total butterfat yield. The results indicated that beneficial oils are those containing a large proportion of saturated fatty acids. This experimental technic proved very efficient, experimental errors being generally lower than those usually obtained in experiments with field crops.

Phosphorus deficiency among cattle in Pennsylvania, E. B. FORBES and S. R. JOHNSON (*Pennsylvania Sta. Bul.* 371 (1939), pp. 25, figs. 20).—Numerous cases of phosphorus deficiency in cattle are described and illustrated, along with a description of the existing feeding conditions in each instance. This survey led to the conclusion that definite phosphorus deficiency of cattle in the State is a rare disorder and is likely to occur only when animals are wintered largely or exclusively on the less nutritive roughages, such as cereal straw and corn stover, without adequate allowance of grain or other concentrate feed. Preventing normal access to sunshine serves to aggravate the effect of phosphorus deficiency. It may be found in cattle of either sex at any age, but is most likely to occur in heavy milking cows. Good feeding and management practices are recommended as the best preventive of this disorder. Bonemeal is recommended in cases where a concentrated phosphatic supplement is required.

On alimentary acetonuria and ketonuria in dairy cattle induced by feeding grass silage of the butyric acid type, E. BROUWER and N. D. DIJKSTRA (*Jour. Agr. Sci. [England]*, 28 (1938), No. 4, pp. 695-700).—When a group of cows was fed grass silage containing approximately 2 percent butyric acid, the urine consistently gave a positive test for acetone and was relatively high in ketone bodies and ammonia, whereas in a control group receiving hay the urine was negative for acetone and much lower in ketone bodies and ammonia. When the rations of the two groups were reversed the characteristics of the urine were promptly reversed, indicating that the acetonuria was of nutritional origin, probably due to the incomplete oxidation of the butyric acid of the grass silage. The reaction of the urine remained alkaline and the ammonia content was within a normal range, showing that there was no real acidosis. Clinically the cows receiving silage never appeared to be ill.

The practical application of age conversion factors to dairy cattle production (butterfat) records, A. H. WARD and J. T. CAMPBELL (*Jour. Agr. Sci. [England]*, 28 (1938), No. 4, pp. 509-522).—An analysis of the records of 702 Jersey cows which had been tested for at least 6 consecutive years in the New Zealand Co-operative Herd Testing Association led to the conclusion

that increases in milk and butterfat production with advancing age cannot be accurately estimated either by a percentage addition to immature records or by a constant addition. The increase can best be represented by a regression formula of the nature $X=aY+b$, where X equals the mature production and Y the immature production.

Breeding for high production, J. R. DICE (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 3, pp. 28-30).—The value of using dairy sires capable of transmitting the factors for high milk and butterfat production is discussed. Methods of evaluating dairy sires on the basis of their progeny performance are outlined.

Relation between conformation and anatomy of cows of unknown producing ability, W. W. SWETT and R. R. GRAVES. (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 3, pp. 199-235, fig. 1).—Body measurements and post-mortem anatomical data were obtained on a large group of cows, of unknown history but showing definite dairy breed characteristics, which were slaughtered in a commercial packing plant. Much wider variations were found to occur in the weights and measurements of the internal organs than in the external body measurements. Live weight was highly correlated with body bulk and many of the individual body measurements, particularly with chest circumference or heart girth. The weights of the heart and liver were the only internal items highly correlated with live weight. The correlations of various items with body widths were generally definitely lower than corresponding ones for body depths, the differences being most marked at the fore chest and progressively less at the rear chest and paunch. Heart weight was moderately correlated with depth of chest and depth, length, and volume of the thoracic capacity, but showed low correlation with width of body, width of thoracic cavity, breadth and length of body, and with other internal organs except the liver. Correlations for lung weight were generally lower than for heart weight. The length of the intestines generally showed a low magnitude of correlation with other items. Certain breed differences are discussed.

Growth and development, with special reference to domestic animals.—L. The influence of fasting and refeeding on milk production, heat production, and respiratory quotient, L. E. WASHBURN, S. BRIDY, and A. C. RAGSDALE (*Missouri Sta. Res. Bul.* 295 (1939), pp. 24, figs. 8).—This series of studies has been continued (E. S. R., 80, p. 245). The data summarized include one lactating cow and one dry dairy cow and two lactating and two dry goats, in addition to data for rats previously described (E. S. R., 79, p. 374). Time curves are presented for the absolute and relative milk production, milk composition, heat production, respiratory quotient, and methane production during advancing fasting and on refeeding for these three species. The heat production of lactating animals was consistently much higher than for non-lactating animals. With all three species there was a parallel decline in the percentage milk production, heat production, and respiratory quotient with advancing fasting, and parallel increases on refeeding. It is concluded that it is not possible either with ruminants or rats to determine the basal heat production during normal lactation because normal lactation appears to be incompatible with the postabsorptive state.

The influence of various fodder supplements on the production and the nutritive value of winter milk, S. BARTLETT, A. G. COTTON, K. M. HENRY, and S. K. KON (*Jour. Dairy Res.* [London], 9 (1938), No. 3, pp. 273-309, figs. 8).—In the experiment noted four groups of cows, at the National Institute for Research in Dairying, without access to green feed received typical winter rations supplemented with mangels (control group), artificially dried grass,

sprouted corn, and kale, respectively. Over an 11-week experimental period no significant differences were found between any of the supplements in their effect on the yield of milk or the fat and solids-not-fat content of the milk. The addition of kale or artificially dried grass materially increased the carotene and vitamin A content of the milk, while sprouted corn gave results similar to mangels in this respect. There was no significant difference in the vitamin B complex contained in milk produced on the mangels, dried grass, and sprouted corn rations. The vitamin B₁ (complex) in milk was varied, but averaged lowest on the sprouted corn ration. The vitamin C content of milk was highest on the sprouted corn ration, followed in order by the kale, mangels, and dried grass milks.

Four series of rat feeding tests were conducted to compare the nutritive value of these milks. The milks were fed supplemented with minerals alone or with minerals and sugar, each ration being fed ad libitum and on an equalized intake basis. No differences were found in the growth-promoting properties of the different milks, leading to the conclusion that under the conditions of this experiment the technic failed to reveal the presence of a new essential dietary factor. Probable reasons for differences in these findings and those reported by the Wisconsin Experiment Station (E. S. R., 78, p. 527) are discussed at length.

Studies on the blood precursors of milk protein, E. P. REINEKE, V. E. PETERSON, O. B. HOUGHIN, and C. W. TURNER (*Missouri Sta. Res. Bul.* 296 (1939), pp. 20).—Continuing this line of investigation (E. S. R., 78, p. 689), a comparison of simultaneously drawn arterial and venous blood samples from lactating goats showed that the amino acids absorbed by the mammary glands were insufficient to account for the nitrogen content in the milk. The absorption of amino acid nitrogen by the gland averaged about 0.7 mg. per 100 cc. of plasma. The mammary gland caused considerable shifting of the increments of globulin from one fraction to another, but the uptake of globulin was not constant for any specific fraction. It was found that the gland may absorb fibrinogen, globulin, or albumin from the blood stream, with a return to the venous blood of one or more of these substances. This suggests that these proteins may undergo a reversible series of transformations in the mammary gland from albumin to globulin to fibrin. Arterio-venous differences frequently showed the mammary gland to be in negative nitrogen balance, and variations in the nitrogen content of samples from moment to moment were great enough to mask sometimes the amount of nitrogen actually involved in milk secretion.

The composition of the blood and milk of lactating cows during inanition, with a note on an unidentified constituent present in certain samples of abnormal milk, J. A. B. SMITH, G. R. HOWAT, and S. C. RAY (*Jour. Dairy Res. [London]*, 9 (1938), No. 3, pp. 310–322).—The yield and composition of milk secreted by cows and the composition of their blood during a 12-day fast were determined and compared with the values secured during the prefast and post-fast periods. Milk yields dropped rapidly during the fasting period, although the three animals varied somewhat in this respect. The protein content of the milk rose considerably so that there was an increase of approximately 20 percent by the ninth day of fast, and these high values persisted for several days after feeding was resumed. The percentage of fat rose sharply, reaching values of from two to three times normal. However, the total yield of fat showed a daily decline throughout the period of fasting. When the simple starvation was unaccompanied by milk fever or other complications, the lactose content and the chloride : lactose ratio varied only slightly from normal. An unidentified

constituent appeared in the milk during fast, which in some cases amounted to about 2 percent of the milk or nearly 20 percent of the solids-not-fat. The phosphatase content of the milk increased markedly, while only slight and inconsistent variations in blood phosphatase occurred. Blood sugar and the blood corpuscle volume tended to rise slightly, and blood chloride levels declined during inanition.

The diffusion of trimethylamine oxide from the udder, W. L. DAVIES (*Jour. Dairy Res. [London]*, 9 (1938), No. 3, pp. 323-326).—Continuing this line of investigation (E. S. R., 76, p. 236), a neutral solution of pure trimethylamine oxide was injected into two quarters of a lactating udder. These quarters increased in turgidity up to 2.5 hr. after injection and then relaxed. The oxide diffused rapidly out of the quarters from 3 to 4 hr. after injection, and a maximum concentration appeared in the urine by the end of the third hour. Within a period of 83 hr. after injection, 76 percent of the diffusible oxide was recovered in the urine, milk obtained 7 hr. after injection containing from 7 to 8 mg. percent of the tertiary nitrogen.

The chloride content of milk, W. L. DAVIES (*Jour. Dairy Res. [London]*, 9 (1938), No. 3, pp. 327-335, figs. 3).—The magnitude and frequency of variations in the chloride content of 7,502 samples of milk are reported. The mode of morning samples of all breeds was from 81 to 90 mg. percent and of evening samples from 71 to 80. The mode for Guernseys and Shorthorn milks was from 71 to 80 and for all other samples from 81 to 90. The averages for Shorthorn, Guernsey, the institute herd, all samples, special Friesian milk of low solids-not-fat content, and the bulk institute milk were 97, 93, 93, 98, 128, and 85 mg. percent, respectively. The influence of other factors, such as breed, age, lactation period, number of lactations, season, and udder troubles, is discussed.

The methylene blue reduction test and the keeping quality of milk, C. H. CHALMERS (*Jour. Dairy Res. [London]*, 9 (1938), No. 3, pp. 351-355).—A study was made of the relationship between reduction time and keeping quality of milks held for 1, 7, 16, and 23 hr. at 15° C. before testing. The following coefficients of correlation were obtained—at 23 hr. 0.954 ± 0.004 , at 16 hr. 0.893 ± 0.015 , at 7 hr. 0.68 ± 0.055 , and at 1 hr. 0.442 ± 0.059 . Apparently examining milk by the methylene blue reduction test within a few hours after it is produced gives a very misleading indication of its keeping quality.

Improving milk color, H. H. TUCKER (N. J. Expt. Stas.). (*Guernsey Breeders' Jour.*, 55 (1939), No. 4, pp. 279, 281, 282).—A mixture of fresh carrots and tops and green corn in the proportion of 1:3 was ensiled without preservatives. In feeding trials, a group of four Guernseys and two Holsteins were fed a ration of grain, beet pulp, and hay for a 3-week preliminary period, followed by two successive 3-week periods in which the carrot-corn silage replaced the beet pulp in the ration. A second comparable group was similarly fed except that the beet pulp ration replaced the carrot-corn silage ration during the third experimental period. The carrot-corn silage proved very palatable. No significant differences were noted in average yield of milk or fat content of the milk for the two groups. An increase in the color of the milk occurred in each group during the first period on the carrot-corn silage, and a further increase in milk color occurred in group 1 during the second period on this ration, while in group 2 the milk promptly declined to approximately the original level when beet pulp replaced the carrot-corn silage. The carrot-corn silage increased the color of the milk to a greater degree in cows producing low-color milk than in those producing high-color milk.

Physical state of fat and losses in centrifuging, H. E. ROSS (Cornell Univ.). (*Milk Plant Mo.*, 27 (1938), No. 12, pp. 30, 31).—Numerous samples of

milk were each divided into two equal lots, one of which was cooled to 50° F. and held at that temperature for 30 min. The other was held at a temperature of 115° for 30 min., after which time both lots of milk were adjusted to a temperature of 85° and run through the same separator. In practically all cases a greater loss of fat in the skim milk occurred in the samples held at the lower temperature, the average loss in these lots being 0.028 percent greater than in the samples held at the higher temperatures. Apparently the physical condition of the fat was the controlling factor in such losses.

The pasteurization of milk, C. J. BABCOCK (*U. S. Dept. Agr. Leaflet 177* (1939), pp. 4).—The status of pasteurization, facts concerning pasteurized milk, and methods for home pasteurization are briefly discussed.

[A study of the crumbly butter problem in Oregon] (*Oregon Sta. Circ. 130* (1938), pp. 32, 33, figs. 4).—A study of the chemical and physical properties of butterfat produced in the alfalfa sections of eastern and southern Oregon showed marked seasonal changes in the fat, that produced during the winter season when large quantities of alfalfa were fed tending to be hard while that produced in other seasons was relatively soft. Preliminary findings indicated that certain variations in the feeding program and in the butter manufacturing process gave some improvement in the body and texture of the butter.

An apparatus for measuring the elastic and plastic properties of cheese curd, G. W. SCOTT BLAIR (*Jour. Dairy Res. [London]*, 9 (1938), No. 3, pp. 347-350, fig. 1).—The apparatus described has proved effective for measuring the elastic and plastic deformations of cheese curd under a compressive load at the time it is ready for cutting. A figure inversely proportional to shear modulus was obtained with considerable accuracy, and is a good criterion of firmness for indicating the optimum time to cut the curd.

The solubility of Cheddar cheese curd in sodium chloride solutions, F. H. McDOWALL and L. A. WHELAN (*Jour. Dairy Res. [London]*, 9 (1938), No. 3, pp. 339-341).—It was found that the proteins of cheese were approximately 100 percent soluble in 3 and 10 percent solutions of sodium chloride within 7 days after manufacture and remained at this value throughout the life of the cheese, thus indicating that the effect of salt concentration on cheese quality is not attributable to variations in the solubility of the proteins in the brine.

The composition of cheese rinds, W. L. DAVIES (*Jour. Dairy Res. [London]*, 9 (1938), No. 3, pp. 342-346).—The composition of the rinds of a number of English, Canadian, and New Zealand Cheddar cheeses and of three Stilton cheeses is reported. The rind of ripened Cheddars contained from 15 to 20 percent of moisture, while that of unripened Cheddars contained up to 27 percent. The rinds were lower in fat, higher in protein, and also higher in calcium and phosphorus and in calcium:phosphorus ratio than the interior of the cheeses. The fiber content of the rinds was negligible.

The organisms causing rusty spot in Cheddar cheese, R. S. BREED and C. S. PETERSON. (*N. Y. State Expt. Sta.*). (*Jour. Bact.*, 36 (1938), No. 6, p. 667).—A brief résumé.

Factors affecting the activity and heat resistance of Swiss cheese starter cultures.—I, Influence of time and temperature of incubation, P. R. ELLIKER and W. C. FRAZIER. (*Univ. Wis.*). (*Jour. Dairy Sci.*, 21 (1938), No. 12, pp. 801-813, figs. 2).—Cultures of *Lactobacillus helveticus* and *Streptococcus thermophilus* were considered in these studies. When carried through numerous transfers at temperatures of 30°, 35°, 37°, 40°, and 42° C., cultures of the former incubated at 37° or 40° were more active following heat treatment than those at 30°, 35°, or 42°, while the latter showed greater heat resistance when grown at 30°, 35°, or 37° than 40° or 42°. The 37° cultures of the former were

more heat resistant than the 40° cultures after the first 12-hr. transfer, but after numerous transfers this situation was reversed, and the 40° culture did not lose this increased heat resistance by one transfer at lower temperature. The 37° cultures of the latter were consistently more heat resistant than the 40° cultures after numerous transfers. Cultures of *L. helveticus* incubated at 37° or 40° for from 12 to 16 hr. were far more heat resistant than cultures incubated at the same temperatures for from 7 to 8 hr., but no marked differences occurred in activity following heat treatment of *S. thermophilus* cultures incubated at 37° within a range of from 6 to 16 hr.

The influence of methods of handling thermoduric lactics on the heat resistance of subcultures, H. J. PEPLER and W. C. FRAZIER. (Univ. Wis.). (*Jour. Bact.*, 36 (1938), No. 6, p. 658).—Cultures of *Lactobacillus helveticus* and *Streptococcus thermophilus* were carried continuously at 37° C., being transferred at 12- and at 24-hr. intervals and also at 37° following varying holding periods at 20°. After each culture had been transferred at least 7 consecutive times, fresh cultures were heated for 30 min. at 60° and then incubated at 37° to determine the rate and amount of growth and the degree of acid development. All cultures of the former carried continuously at 37° were equal in growth and acid production following heat treatment. Cultures of the latter transferred at 12-hr. intervals at 37° excelled those transferred at 24-hr. intervals in rate of growth and acid production. Incubation of either organism at 20° for periods longer than 36 hr. markedly reduced their activity.

VETERINARY MEDICINE

[The life work of Theobald Smith] (*Med. Classics*, 1 (1937), No. 5, pp. [1]+341-669, pls. [11], figs. 7).—This brief contribution on the writings of T. Smith (E. S. R., 72, p. 289), with a bibliographical list of 224 titles and an index, reprints the report on Investigations into the Nature, Causation, and Prevention of Southern Cattle Fever, by T. Smith and F. L. Kilborne (pp. 372-578) (E. S. R., 5, p. 608), and A Comparative Study of Bovine Tubercle Bacilli and of Human Bacilli from Sputum, by T. Smith (pp. 599-669) (E. S. R., 10, p. 691).

[Work in animal pathology and parasitology by the Iowa Station] (*Iowa Sta. Rpt. 1938*, pt. 1, pp. 97-99, 145, 150-153).—The work of the year reported (E. S. R., 79, p. 534) includes the etiology of range paralysis in poultry and the egg as a possible mode of its transmission in chickens, both by C. Murray, C. D. Lee, and H. L. Wilcke; the effect of dietary constituents on coccidiosis in domestic fowl, by Becker and Wilcke; breeding for resistance to fowl typhoid in poultry, by E. W. Lindstrom, J. W. Gowen, and N. F. Waters; and genetic investigation of resistance and susceptibility of typhoidlike diseases in laboratory animals, by Lindstrom and Gowen.

[Research work in animal pathology by the Oregon Station] (*Oregon Sta. Circ. 130* (1939), pp. 8, 9, 42, 43, figs. 9).—Brief reference is made in this preliminary report of research work to the causes of four range diseases of sheep, namely, lung disease, stiff lambs, lamb dysentery, and pregnancy disease, and to poultry diseases, including laryngotracheitis, coccidiosis, pullorum disease, neoplastic disease, and diseases of the turkey.

[Work in animal pathology and parasitology by the South Carolina Station] (*South Carolina Sta. Rpt. 1938*, pp. 75, 76, 81, 98, 99).—The work of the year reported (E. S. R., 79, p. 300) relates to a study of the effect of kidney worms upon the growth of swine, by G. W. Anderson, of bovine mastitis, by Anderson, J. P. LaMaster, and G. H. Wise, and of methods of sanitation in the control of kidney and round worms of swine, by E. D. Kyzer, R. L. Jones, and Anderson.

[Work in animal pathology and parasitology by the Texas Station] (*Texas Sta. Rpt. 1937*, pp. 12-17, 24, 40, 41, 136, 266-270, 271).—The work of the year with livestock affections (E. S. R., 79, p. 103) briefly reported relates to loin disease in cattle, by H. Schmidt; anaplasmosis in cattle, by Schmidt and P. L. Piercy; infectious bovine abortion, by Schmidt, R. D. Turk, and O. C. Copeland; trichomonad abortion in cattle, by Schmidt, Turk, and C. N. Shepardson; loco weed poisoning (coop. U. S. D. A.), jimmies in sheep and goats, and miscellaneous poisonous plants (including red-stemmed pea vine (*Astragalus emoryanus*), *sacahuista* (*Nolina texana*), *Sartioellia flaveriae*, and two species of *Senecio* (*S. longilobus* and *S. riddellii*)), all by F. P. Mathews; loco poison, by J. Semb; disease resistance in animals, by B. L. Warwick, Schmidt, and Turk; at the Sonora Substation, swellhead of sheep and goats, hard yellow livers of sheep and cattle, contagious ecthyma (soremouth) of sheep and goats, stomach worms (*Haemonchus contortus*) of sheep and goats, infectious enterotoxemia of young lambs, and miscellaneous feeding trials of suspected plants, all by I. B. Boughton and W. T. Hardy.

[Work in animal pathology by the Wisconsin Station] (*Wisconsin Sta. Bul. 442* (1938), pp. 52-55, 57, 58, 64, 65, fig. 1).—The work of the year in animal pathology (E. S. R., 78, p. 847) relates to the treatment of chicks with sulfur for coccidiosis, by C. E. Holmes, J. G. Halpin, and C. A. Herrick; the susceptibility of turkeys to chicken coccidia and chickens to turkey coccidia; the accuracy of the blood agglutination test for Bang's disease; the resistance of cows to Bang's disease, by M. R. Irwin and L. C. Ferguson (coop. U. S. D. A.); the part if any, that viruses play, in causing mastitis, by E. G. Hastings, E. H. Peterson, and F. B. Hadley; and further tests on tuberculins.

[Contributions on animal parasitology] (*Jour. Parasitol.*, 24 (1938), No. 6, Sup., pp. 8, 9, 10, 11, 12-19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32-36).—Among the abstracts of contributions presented at the annual meeting of the American Society of Parasitology held in Richmond, Va., in December 1938 are the following: Comparative Efficiency of Various Technics for the Discovery of Protozoa and Helminths in Feces, by E. C. Faust, W. Sawitz, J. Tobie, V. Odom, C. Peres, and D. Lincicome (p. 8); Hematoxylin Staining of Protozoan Cysts Obtained From Feces by Zinc Sulphate Levitation, by H. S. Nickel (pp. 8, 9); *Bufo marinus* as a Vector of Helminth Ova in Puerto Rico, by W. A. Hoffman and J. L. Laner (p. 10); Preliminary Report on the Incidence of Trichinosis in Alabama, by J. H. Walker and C. G. Breckenridge (p. 10); Studies on the Protective Power of Serum From Dogs Actively Immunized Against *Ancylostoma caninum*, by G. F. Otto (pp. 10, 11); The Possible Role of Birds in the Epidemiology of Sylvatic Plague, by W. L. Jellison (p. 12); The Tick *Ornithodoros hermsi* as Probable Vector of Relapsing Fever in Northern Idaho, by C. B. Philip and G. E. Davis (p. 12); Blood Alterations in Typhlohepatitis of Turkeys, With Notes on the Disease, by E. P. Johnson and C. J. Lange (p. 12) (Va. Expt. Sta.); Cultures of *Pentatrichomonas* sp. in vitro From the Livers of Chickens and Turkeys, by E. A. Allen (p. 13), and Domestic Fowls as Carriers of the Poultry Gapeworm [*Syngamus trachea*], by E. E. Wehr (p. 13) (both U. S. D. A.); Goblet Cells and Age Resistance to Parasitism, by J. E. Ackert and S. A. Edgar (p. 13), and Effects of the Tapeworm *Railletina cesticillus* (Molin) on Growing Chickens, by J. E. Ackert and A. A. Case (p. 14) (both Kans. State Col.); Susceptibility of Chickens to Reinfection With *Railletina cesticillus* as Determined by the Presence of the Original Terminal Segment, by G. W. Luttermoser (pp. 14, 15) (U. S. D. A.); A Method for Testing the Role of Host Activity in Coccidian Periodicity, by D. C. Boughton (p. 15) (Univ. Ga.); Dried Milk Products in the Ration and Mortality With Cecal Coccidiosis in Chicks,

by E. R. Becker and P. H. Waters (p. 15) (Iowa State Col.); Observations on *Eimeria bukidonensis* in New York State Cattle, by D. W. Baker (pp. 15, 16) (Cornell Univ.); Fifteen Cases of Experimental Bovine Venereal Trichomoniasis, by C. W. Rees (p. 16) (U. S. D. A.); Sterile Culture of the Free-Living and Parasitic Larval Stages of *Haemonchus contortus*, by R. W. Glaser and N. R. Stoll (p. 16); The efficacy of Phenothiazine for the Removal of Ascarids and Nodular Worms From Swine, by P. D. Harwood, A. C. Jerstad, and L. E. Swanson (pp. 16, 17) (U. S. D. A.); New Intermediate Hosts of the Fowl Tapeworm *Raillietina cesticillus* (Molin), by A. A. Case and J. E. Ackert (p. 17) (Kans. State Col.); Barium Antimonyl Tartrate as a Remedy for the Removal of Gapeworms from Chickens, by E. E. Wehr, P. D. Harwood, and J. M. Schaffer (p. 17), and Hemorrhage as the Cause of the Fatal Anemia Associated With Stomach Worm Infection in Sheep, by J. S. Andrews (pp. 17, 18) (both U. S. D. A.); A Study of the Periodicity and Synchronicity of the Pigeon Strain of *Plasmodium relictum*, by G. R. Coatney (p. 18); Cross Immunity Reactions in Avian Plasmodia, by F. Wolfson (pp. 18, 19); Studies on Immunity in Avian Malaria, With Special Reference to *Plasmodium circumflexum*, by R. D. Manwell and F. Goldstein (p. 19); Acquired Immunity to Ticks, by W. Trager (p. 20); The Localization of Glycogen in *Macracanthorhynchus hirudinaceus*, by T. von Brand (p. 21); Hemoglobin in Turtle Parasites, by G. W. Wharton (p. 21); A Study of *Haemoproteus sacharovi* in Pigeons and Mourning Doves With Notes on *H. maccalumi* of Mourning Doves, by G. R. Coatney and E. West (p. 21); Invasion of Young Red Blood Cells by Merozoites of Human and Avian *Plasmodium*, by R. Hegner (p. 21); Two Types of *Toxoplasma*-like Bodies in Canaries, by F. Wolfson (p. 22); A Staining Technique for Demonstrating Avian Malaria Parasites in Tissue Sections, by R. Hewitt (pp. 22, 23); *Lucilia* sp. Attacking Sheep at Beltsville, Maryland, by P. D. Harwood and A. C. Jerstad (pp. 23, 24) (U. S. D. A.); Parasite Studies on Ring-Necked Pheasants (*Phasianus colchicus torquatus*) (Gmelin) in Minnesota, by O. W. Olsen (pp. 24, 25), and A Hawk Tapeworm Which Produces a Proliferating Cysticercus in Mice, by L. R. Penner (p. 25) (both Univ. Minn. et al.); Variability in Hook Measurement in the Acanthocephala, by H. J. Van Cleave (p. 25) (Univ. Ill.); *Schistosomium* From the Muskrat *Ondatra zibethica* in Minnesota and Michigan, by L. R. Penner (p. 26) (Univ. Minn. et al.); Studies on the Pre-cercarial Development of *Stichorchis subtriquetrus* (Trematoda: Paramphistomidae), by H. J. Bennett and A. G. Humes (p. 27) (La. State Univ.); On the Life Cycle of a Tapeworm, *Diphyllobothrium* sp., From the Herring Gull *Larus argentatus* Pont., by L. J. Thomas (pp. 28, 29) (Univ. Ill.); Life History of the Cecal Fluke *Postharmostomum gallinum* of Poultry, by J. E. Alicata (p. 29) (Univ. Hawaii); Observations on the Life History of *Spelotrema nicolli* n. sp. (Trematoda: Microphallidae), With the Description of a New Microphallid Cercaria, by R. M. Cable and A. V. Hunninen (pp. 29, 30) (Purdue Univ. et al.); The Life History of *Zygocotyl tunatum*, by C. H. Willey (p. 30); The Development of *Cercaria burti* Miller, 1923, in Leeches and Ducks, by C. H. Willey and Y. Rabinowitz (pp. 30, 31); Experimental Studies on *Posthodiplostomum minimum* (MacCallum, 1921), a Trematode From Herons, by M. S. Ferguson (p. 31); Age Resistance of Rats Against *Trypanosoma lewisi* and *Trypanosoma cruzi*, by J. T. Culbertson, M. H. Kolodny, and C. J. Duca (p. 32); Effects of Number and Age of Worms on Development of Primary and Secondary *Hymenolepis diminuta* Infections in Rats, by A. C. Chandler (pp. 32, 33); Specificity of Artificial Acquired Immunity to *Strongyloides ratti*, by A. J. Sheldon (p. 33) (Univ. N. C.); Constitutionally Dissimilar Lines of *Strongyloides ratti*, by G. L. Graham (p. 33); Studies on Dietary Deficiencies and Iron Salts in Ex-

perimental Canine Hookworm Infections, by G. F. Otto and J. W. Landsberg (pp. 33, 34); Three New Nematocides With a Consideration of Factors Governing Nematocidal Efficacy, by B. G. and M. B. Chitwood (p. 34), and Critical Tests With Iso-amyl-ortho-cresol for the Removal of Worms From the Dog, by A. C. Jerstad (pp. 34, 35) (both U. S. D. A.); The Effect of Dosage and Interval After Infection on Passive Immunity to the Nematode *Nippostrongylus muris*, by M. P. Sarles and W. H. Taliaferro (p. 35); Rapid Loss of *Trichinella* Larvae Fed to Immune Rats and Its Bearing on the Mechanism of Immunity, by O. R. McCoy (p. 35); A Note on the Cultivation of *Taenia taeniaeformis* Larvae in vitro, by J. H. Wilmoth (pp. 35, 36); and Development of the Microfilaria of *Dirofilaria scapiceps* (Leidy, 1886) in Mosquitoes of Minnesota, by P. R. Highby (p. 36) (Univ. Minn.).

Changes in the names of worms: The rules of zoological nomenclature as applied to veterinary helminthology, J. N. OLDHAM (*Vet. Rec.*, 50 (1938), No. 36, pp. 1131-1137, 1138).—A five-page list of corrected names of helminths as now generally accepted and of some of the commoner synonyms is given.

Parasites of some Minnesota Cricetidae and Zapodidae, and a host catalogue of helminth parasites of native American mice, A. B. ERICKSON. (Univ. Minn.). (*Amer. Midland Nat.*, 20 (1938), No. 3, pp. 575-589, figs. 18).—Descriptions of five new species and the erection of the genus *Spiruracerca* are followed by a host list.

Tapeworm studies.—VII, Variation in pasture infestation with *M[oniezia] expansa*, N. R. STOLL (*Jour. Parasitol.*, 24 (1938), No. 6, pp. 527-545, figs. 5).—This report of further studies (*E. S. R.*, 80, p. 685) includes a list of 24 references to the literature.

The rate of egg production of *Strongylus equinus* and *Strongylus vulgaris* as measured by egg counts and qualitative larval cultures, J. W. BERTON (*Jour. Parasitol.*, 24 (1938), No. 6, pp. 517-520, fig. 1).—A report is made of the egg-laying capacities of adult female *S. vulgaris*, *S. equinus*, and *S. edentatus* as determined by means of an egg count-larval culture method and post-mortem examinations for worms.

Capsulation, "diffusion factor," and serological behaviour of group-B streptococci (*Streptococcus agalactiae*), D. F. STEWART (*Austral. Vet. Jour.*, 14 (1938), No. 5, pp. 180-183).—In the course of studies of hemolytic and non-hemolytic strains it was found that certain of the group-B streptococci produce a diffusion factor. This power is not associated with the presence of capsules but appears to be a quality of the strain. No evidence was obtained that group-B streptococci form capsules.

Infection of the central nervous system by louping ill virus, F. M. BURNET and D. LUSH (*Austral. Jour. Expt. Biol. and Med. Sci.*, 16 (1938), No. 3, pp. 233-240).—A report of an investigation by the quantitative egg membrane technic.

[Studies of the tolerance of animals for lead and arsenic]. (U. S. D. A.). (*Jour. Pharmacol. and Expt. Ther.*, 64 (1938), No. 4, pp. 364-464, figs. 6).—The results of experimental studies conducted to establish the satisfactory tolerances for lead and arsenic in residues remaining on fruits and vegetables from the application of insecticides are reported as follows: The Chronic Effects on Dogs of Feeding Diets Containing Lead Acetate, Lead Arsenate, and Arsenic Trioxide in Varying Concentrations, by H. O. Calvery, E. P. Laug, and H. J. Morris (pp. 364-387); The Effect of Lead on Rats Fed Diets Containing Lead Arsenate and Lead Acetate, by E. P. Laug and H. J. Morris (pp. 388-410); The Storage of Arsenic in Rats Fed a Diet Containing Calcium Arsenate and Arsenic Tri-

oxide, by H. J. Morris and E. W. Wallace (pp. 411-419); The Growth and Reproduction of Rats Fed Diets Containing Lead Acetate and Arsenic Trioxide and the Lead and Arsenic Content of Newborn and Suckling Rats, by H. P. Morris, E. P. Laug, H. J. Morris, and R. L. Grant (pp. 420-445); The Influence of Calcium and Phosphorus on the Storage and Toxicity of Lead and Arsenic, by R. L. Grant, H. O. Calvery, E. P. Laug, and H. J. Morris (pp. 446-457); and Variations in the Arginase Concentrations in the Livers of White Rats Caused by the Administration of Arsenic and Lead, by H. D. Lighbody and H. O. Calvery (pp. 458-464).

Phenol-contaminated waters and their physiological action, V. G. HELLER and L. PURSELL. (Okla. Expt. Sta.). (*Jour. Pharmacol. and Expt. Ther.*, 63 (1938), No. 2, pp. 99-107, fig. 1; *abs. in Okla. Sta. [Bien.] Rpt.* 1937-38, pp. 4, 5).—Report is made of extensive tests of waters contaminated by phenolic wastes from refineries, factories, and mines, conducted with rats during a period of 3 yr. It is concluded that "phenol even in appreciable concentrations is apparently not toxic to animals. A large amount of phenol is rapidly conjugated and eliminated in the urine as fast as absorbed and considerable seems to be metabolized or lost. The presence of concentrations less than 1 percent seems not to interfere with normal digestion, absorption, or other metabolic functions." Modified methods of analysis which eliminate some of the interfering materials are suggested.

Suckleya suckleyana, a poisonous plant, F. THORP, JR., and A. W. DEEM. (Colo. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 3, pp. 192-197, figs. 3).—During the course of a limited survey of the plains section of north-eastern Colorado, *S. suckleyana* was found growing in a number of water holes and irrigation reservoirs. Field evidence has indicated that this plant has been responsible for numerous cattle losses in that section of the State. It has been found by chemical analysis and feeding tests to be cyanogenetic, and the qualitative test for hydrocyanic acid was positive for every specimen examined. "Quantitative tests showed a variation of hydrocyanic acid concentration from 0.0364 to 0.002 percent, as compared with 0.0135 percent contained in a sample of stunted cane. The *S. suckleyana* which had the highest hydrocyanic acid concentration (0.0364 percent) proved, when force-fed, to be toxic for cattle, sheep, rabbits, and guinea pigs. Symptoms of intoxication developed rapidly, followed by death or a quick recovery, depending on the quantity administered. The sodium nitrate and sodium thiosulfate treatment brought about rapid recovery in one heifer which showed increasingly progressive symptoms of intoxication induced by artificial feeding."

Infectious laryngo-tracheitis, T. G. HUNGERFORD (*Agr. Gaz. N. S. Wales*, 49 (1938), Nos. 11, pp. 628-632, figs. 6; 12, pp. 679-683, fig. 1).—An account of this disease, which is widespread in New South Wales, the mortality varying in different outbreaks from 2 to over 80 percent.

Experiments on contagious abortion: Immunisation studies with vaccines of graded virulence, A. D. McEWEN and F. W. PRESTLEY (*Vet. Rec.*, 50 (1938), No. 35, pp. 1097-1105, 1106).—By serial passage of a nonvirulent strain of *Brucella abortus* through guinea pigs, its virulence was progressively restored. Guinea pigs were vaccinated with this nonvirulent strain and with relatively nonvirulent variants of the strain obtained by guinea pig passage. The animals vaccinated with one or other of the passaged variants which had regained some slight degree of virulence were more resistant to infection than animals vaccinated with the original nonvirulent strain.

"Vaccination with the passaged variant possessing the highest degree of virulence conferred the highest degree of protection. This variant was rough,

and vaccination with it did not stimulate demonstrable smooth agglutinins in guinea pigs. It is therefore concluded that an actively produced resistance to *B. abortus* infection has not any dependence on smooth agglutinins, and that there is not necessarily any relation between the antigen responsible for the stimulation of smooth agglutinins and those properties of the bacterial cells which stimulate resistance to infection. It is possible that these latter are possessed in greater quantity by strains of some degree of virulence than by nonvirulent strains. On the other hand, the longer persistence of strains of some degree of virulence in the tissues, rather than any specific quality associated with virulence, may be responsible for the superior immunizing properties of these strains over a nonvirulent strain.

"The experiments suggest that guinea pigs may have their resistance gradually enhanced by successive vaccinations with strains of gradually increasing degrees of virulence and the possibility of adopting a similar procedure in the immunization of cattle."

The concentration of sulfanilamide in the blood and milk of cattle and its effect on *Brucella abortus* and streptococcal infections of the bovine udder, W. T. MILLER, C. K. MINGLE, F. M. MURDOCK, and J. O. HEISHMAN. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 3, pp. 161-171, figs. 6).—Studies of the concentration of sulfanilamide in the blood and milk of lactating and dry cows and its effect upon bacterial organisms are reported upon, the details being given in tables and charts. It was found that a concentration of 15 mg. or more in 100 cc. could be produced in the blood and milk by giving an initial dose of 0.4 gm. per kilogram, and further, this level could be maintained by subsequent dosages of from 0.15 to 0.2 gm. per kilogram at 12-hr. intervals. Dry cows appear to concentrate the sulfanilamide in the blood more rapidly than lactating cows. Direct culture of the milk failed to show that this drug had any bactericidal action in *B. abortus* infection of the udders of the five lactating cows treated. Neither were any significant changes observed in the agglutination titers of the blood and milk. No change was observed in the condition of one of the two cows with udder infections caused by streptococci of Lancefield's group B that were treated with large doses of sulfanilamide, but the infection was apparently completely eliminated from the other cow. The administration of large doses of sulfanilamide resulted in a decrease in appetite and milk production in the treated animals, and a rise in temperature was observed immediately following termination of the treatment.

The wild rat as a host of *Brucella abortus*, C. P. FITCH and L. M. BISHOP. (Minn. Expt. Sta.). (*Cornell Vet.*, 28 (1938), No. 4, pp. 304-306).—In cultures made from 66 rats caught in a barn of the Minnesota Experiment Station which houses Bang-infected cattle only 1 was found infected by *B. abortus*. It is pointed out that a larger percentage might readily become infected under less sanitary conditions.

Evidence is accumulating to the effect that the common barnyard rat is a host to *Brucella* infection, that infection may pass from rat to rat by living in close contact and, furthermore, that *B. abortus* may be found in the urine and feces of rats. It might well be that abortion may occur in rats, although as yet it has not been demonstrated, and that aborted rat fetuses and fetal membranes may also be a source of contamination of foodstuffs of other animals. It is suggested that extermination of rats on farms infected with Bang's disease be one of the measures of sanitation recommended when an attempt is made to free the farm of this disease.

Pseudomonas aeruginosa in bovine mastitis, J. F. CONE (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 2, pp. 141-147).—Report is made of the finding of *P.*

aeruginosa (*Bacillus pyocyaneus*) to be the cause of an outbreak of bovine mastitis of extreme severity involving 23 cows in the dairy herd of the U. S. D. A. Bureau of Dairy Industry at Beltsville, Md. The onset was sudden and accompanied by fever. With some cows milk production practically ceased during the acute stage of the disease. The affected quarters became blind in two cases and in others they remained hard and swollen, although secreting milk of normal appearance. Some of the cows continued shedding the organisms in small numbers long after the acute attack had subsided and the milk had become normal in appearance. The strains of *P. aeruginosa* isolated from mastitis cases and four strains obtained from other laboratories differed from Bergey's description of the species (E. S. R., 71, p. 28) in their inability to produce indole and their ability to ferment the simpler carbohydrates. The public-health and economic significance of *P. aeruginosa* in milk is discussed briefly. A list of 21 references to the literature cited is included.

The pathology of nonspecific mastitis and consideration of possible etiological agents, E. H. PETERSON, E. G. HASTINGS, and F. B. HADLEY. (Wis. Expt. Sta.). (*Cornell Vet.*, 28 (1938), No. 4, pp. 307-324, figs. 8).—It is concluded that final proof that nonspecific mastitis is or is not a virus disease will have to be furnished by the success or failure of experimental transmission. There is a list of 26 reference to the literature.

Enzootic marasmus: The cobalt content of soils, pastures, and animal organs, E. J. UNDERWOOD and R. J. HARVEY (*Austral. Vet. Jour.*, 14 (1938), No. 5, pp. 183-189).—A continuation of the early work on enzootic marasmus in sheep (E. S. R., 74, p. 260). Cobalt determinations on a number of soils and pastures from healthy areas and from areas where sheep and cattle become affected were carried on. "The cobalt content of the livers of a number of 'affected' and healthy sheep was also investigated. The mean cobalt content of 22 samples of surface soils of those soil types which predominate on affected farms was found to be 0.6 p. p. m. Co on an air-dry basis (range 0.1-1.5). The corresponding figures for 27 samples of typical 'healthy' soil types adjacent to the above were 5.6 p. p. m. Co (range 0.2-32.0) and for 24 samples of soil types from outside healthy districts 10.4 p. p. m. Co (range 0.5-40.0). The mean cobalt content of 7 typical affected pastures was found to be 0.04 p. p. m. Co on dry matter (range 0.02-0.07). The corresponding figure for 11 healthy pastures was 0.16 p. p. m. Co (range 0.03-0.43). An experiment to test the effect of top dressing a typical affected pasture with small amounts of cobalt acetate was carried out. Very large increases in the cobalt content of the herbage were obtained; even 0.5 lb. per acre of this salt raised the cobalt content of the pasture above that of average healthy pasture. The mean cobalt content of the livers of 10 affected sheep was found to be 0.06 p. p. m. Co on dry matter (range 0.03-0.14). The corresponding figure for healthy sheep was found to be 0.28 p. p. m. Co (range 0.03-0.58). These results are considered to confirm fully the hypothesis previously advanced that enzootic marasmus is due to a deficiency of cobalt in the food. The significance of the variability in the analytical figures obtained is discussed in the text."

Observations on the toxicity of fluorine for sheep, A. W. PIERCE (*Austral. Council Sci. and Indus. Res. Bul.* 121 (1938), pp. 35, pls. 6, figs. 3).—Report is made of feeding experiments in which rock phosphate of several sources and fluorine were added daily to the ration of chaffed hay and oats fed to young sheep for a period of 3 yr. The sheep which received 120 mg. or less of fluorine grew normally, ate the same amount of food, and remained in good health throughout the experiment. Those receiving larger doses of fluorine performed normally for about 1 yr., after which their food consumption and weight increase

declined and their health became greatly impaired. The food consumptions of the sheep receiving 160 mg. fluorine as Nauru rock phosphate and 170 mg. fluorine as Florida phosphate were 45 and 60 percent, respectively, of that of the controls during the second half of the experimental period, and the corresponding percentages for their weights at the end of the experiment were 55 and 70. Florida phosphate appeared to be less toxic than Nauru, the general health, food consumption, and weight increase of two of the group receiving the former being scarcely affected by the treatment. Ingestion of fluorine did not reduce the amount of wool grown significantly below that of the control animals. A list of 51 references to the literature is included.

A study of the helminth parasites of lambs in Ontario, A. M. FALLIS (Roy. Canad. Inst., Trans., 22 (1938), pt. 1, pp. 81-128, figs. 30).—This report of a study of the helminth parasites of lambs deals with their distribution within the host, the degree of infestation with various kinds and their seasonal variation, and the geographical distribution of the different species in the area from which the lambs came, the details being given in 12 tables.

In the course of the work 144 lambs received from 24 counties in Ontario lying between the southern boundary, Picton on the east and Wiarton on the north, were examined between April 1935 and July 1936. Eighteen of the 19 species of worms (belonging to 15 genera) found in the lambs were nematodes, the nineteenth being a cestode.

A note on the effect of repeated treatment of sheep for *Haemonchus contortus*, L. E. BOLEY, N. D. LEVINE, and W. G. KAMMLADEL (Univ. Ill.). (Cornell Vet., 28 (1938), No. 4, pp. 296-298).—The results obtained in an attempt to appraise the value of repeated anthelmintic treatment, though made on a small number of animals, confirm and support those reported by other investigators. It is apparent that 4 successive treatments with 1 percent copper sulfate in 4 separate 4-oz. doses on alternate days, followed by 14 consecutive weekly treatments of 1 percent copper sulfate in 4-oz. doses failed to effect complete elimination of the stomach worm (*H. contortus*) from sheep. However, 2 successive weekly treatments with 5 cc. tetrachloroethylene following repeated preliminary treatment with copper sulfate proved slightly more effective, as judged by fecal and post-mortem examinations. Carbon disulfide and nicotine sulfate in repeated doses, like copper sulfate, suppressed but did not completely expel all *H. contortus* from naturally infested sheep.

Tuberculosis of sheep in Uganda, J. CARMICHAEL (Vet. Rec., 50 (1938), No. 36, pp. 1138-1147, fig. 1).—The literature on tuberculosis in sheep is reviewed, and the details are given of 12 cases in sheep in Uganda, 11 of which were caused by the bovine and 1 by the human type of tubercle bacillus. Twenty-eight references to the literature are listed.

Tuberculosis of goats in Uganda, J. CARMICHAEL (Vet. Rec., 50 (1938), No. 36, pp. 1147-1154, fig. 1).—The literature on tuberculosis of goats is reviewed, and the details are given of 10 cases of this disease in goats in Uganda, all of which were caused by the bovine type of tubercle bacillus. Twenty references to the literature are listed.

Pyogenic infection of goats and sheep in Tanganyika Territory, R. L. CORNELL (Vet. Rec., 50 (1938), No. 49, pp. 1653-1657, figs. 2).—A report is made of the isolation of organisms of the genus *Corynebacterium* in pure culture from abscesses and caseous lymphadenitis lesions in goats and sheep, collected in the Mpwapa district of Tanganyika Territory. The morphology, cultural characteristics, fermentation reactions, and pathogenicity for small animals are briefly described. Some infection experiments with goats are recorded.

Narcosis and anesthesia in swine produced by pentobarbital sodium, H. C. H. KERNKAMP. (Minn. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 3, pp. 207, 208).

A note on the prevalence and pathogenic importance of *Hyostrongylus rubidus* in pigs in North Queensland, A. L. CLAY (*Austral. Vet. Jour.*, 14 (1938), No. 5, pp. 194-197).—A report on the findings in an outbreak of the swine stomach worm *H. rubidus* at Atherton, North Queensland. Parasites were present in 52.4 percent of 168 pigs examined at a bacon factory.

Trichomonad flagellates in facial lesions of a pig, R. HEGNER and J. E. ALICATA. (Univ. Hawaii et al.). (*Jour. Parasitol.*, 24 (1938), No. 6, p. 554).

Equine encephalomyelitis diagnosed in Kentucky, L. J. GOSS. (Ky. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 3, pp. 232, 233).—Report is made of a case of equine encephalomyelitis, a study of which has established the presence in Kentucky of the western strain of the causative virus.

Sleeping sickness (encephalomyelitis), F. M. BOLIN (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 3, p. 16).—In referring briefly to this disease and preventive measures, it is pointed out that the horse owner should not depend entirely upon vaccination for its control. Attention should be given to maintaining a good physical condition and protecting horses from mosquitoes, flies, and other biting insects during the sickness season.

Infectious anemia (swamp fever), W. S. GOCHENOUR, C. D. STEIN, and O. L. OSTEN. (*U. S. Dept. Agr., Farmers' Bul.* 1819 (1938), pp. II+10, figs. 4).—A practical account of this disease of the horse and mule.

Susceptibility of cats to tubercle bacilli, T. KUWABARA (*Kitasato Arch. Expt. Med. [Tokyo]*, 15 (1938), No. 4, pp. 318-329, pl. 1).—It is concluded from the results reported that Japanese cats are not susceptible to the human type of the tubercle bacillus but that they are susceptible to the bovine type.

A comparative study of the manifestations and histopathology of canine distemper and experimental fox encephalitis infection in dogs, H. R. KRIESEL (*Cornell Vet.*, 28 (1938), No. 4, pp. 324-330).—In the studies reported nuclear inclusions were found in the tissues of 9 puppies experimentally infected with the virus of fox encephalitis. "In a series of 54 puppies experimentally infected with the virus of canine distemper similar nuclear inclusions were noted in 10 percent of the cases, while cytoplasmic inclusions were found in 63 percent. The nuclear inclusions were observed in hepatic and Kupffer cells, reticuloendothelium of mesenteric lymph glands and spleen, and in glomerular endothelium of the kidney. Cytoplasmic inclusions were detected in epithelium of the bronchi and bile ducts and in reticuloendothelium of liver, mesenteric lymph glands, and spleen. The nuclear inclusions observed in both diseases were found to be composed of minute pink-staining granules, the aggregate of which produced a darker homogeneous-appearing body. Progressive stages of the inclusion-body formation were described. Cytoplasmic inclusions were observed in all of 7 ferrets experimentally infected with the virus of canine distemper."

An intracellular parasite encountered in ferret, N. D. LEVINE, G. L. DUNLAP, and R. GRAHAM (*Cornell Vet.*, 28 (1938), No. 3, pp. 249-251, fig. 1).—Record is made of the presence of an organism, probably of the genus *Cryptococcus* or *Encephalitozoon*, in the liver and spleen of a ferret that had succumbed.

Identification of suspected beaver blood stains, R. FENSTERMACHER and B. S. POMEROY. (Minn. Expt. Sta.). (*Cornell Vet.*, 28 (1938), No. 3, pp. 257-260).

Diseases and parasites of fur-bearing animals and their treatment, E. HEDERGER (*Pelztierkrankheiten und ihre Bekämpfung. München (Munich): F. C. Mayer, 1938, pp. 172, figs. 125*).—An account of the diseases and parasites of the silver fox (pp. 16-90), mink (pp. 91-126), and beaver (pp. 127-168), and their treatment.

Adult poultry mortality of noninfectious origin, R. E. LUBBEHUSEN and J. R. BEACH. (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc., 94 (1939), No. 3, pp. 209-222*).—A report is made of post-mortem examinations of 3,001 chickens from 7 to 36 mo. of age in a study of the pathological conditions of non-infectious origin associated with mortality in the development of culls, the details being given in 8 tables. "Lymphomatous infiltrations were predominant in 7- to 12-month-old chickens, constituting 45.3 percent of lesions in those that died and 65.3 percent in the culls. Each succeeding series has shown an increase in visceral lymphomatosis and a corresponding decrease in neurolymphomatosis. The greatest mortality occurred during the age period of 13 to 18 mo., that is, during the second half of the first year of lay."

Barium antimonyl tartrate as a remedy for the removal of gapeworms from chickens, E. E. WEHR, P. D. HARWOOD, and J. M. SCHAFER. (U. S. D. A.). (*Poultry Sci., 18 (1939), No. 1, pp. 63-65*).—In the experiments here reported barium antimonyl tartrate was the best of the several substances tested for the removal of gapeworms of chickens and was very effective for this purpose. It was dusted over the birds and inhaled by them.

A study of the cellular elements and hemoglobin in the blood of chickens experimentally infected with *Capillaria columbae* (Rud.), O. OLSON and P. P. LEVINE. (Cornell Univ.). (*Poultry Sci., 18 (1939), No. 1, pp. 3-7*).—Observations of the blood cells and hemoglobin of two groups of chickens, one of which was experimentally parasitized with *C. columbae*, are reported upon, the details being given in table form. A leucocytosis of the heterophils and eosinophils and a slight anemia was detected in the infected chickens during the period when clinical symptoms of the infection were manifest. A list is given of 10 references to the subject.

The effect of infection with *Davainea proglottina* on the weights of growing chickens, P. P. LEVINE (*Jour. Parasitol., 24 (1938), No. 6, pp. 550, 551*).—The results of experiments to determine the effect of an infection experimentally produced with the poultry tapeworm *D. proglottina* on the weights of growing chickens are reported, the details being given in table form.

Eimeria hagani n. sp. (Protozoa: Eimeriidae), a new coccidium of the chicken, P. P. LEVINE (*Cornell Vet., 28 (1938), No. 4, pp. 263-266*).—A coccidium found in a culture from scrapings of the wall of the duodenum and intestines of a chicken while conducting a survey of the species of coccidia affecting poultry in New York State is described as new under the name *E. hagani*. The average size of the sporulated oocysts is $19.1\mu \times 17.6\mu$. The time of appearance of the first oocysts in the feces is a little less than 7 days after the infective feeding. Sporulation of the oocyst takes place in from 24 to 48 hr. at 30° C. Round hemorrhagic spots, pinhead in size, are found in the wall of the duodenum and intestine of most infected chickens. Severe infections result in a catarrhal enteritis with the accompanying formation of mucous casts. *E. hagani* was demonstrated by immunity tests to be different from the other species of coccidia that undergo their entire development in the small intestine of the chicken.

[Studies of *Eimeria tenella*], C. C. ELLIS (*Cornell Vet., 28 (1938), No. 4, pp. 267-274*).—Part 1 of this contribution (pp. 267-272) reports upon the viability of the oocysts of *E. tenella*, with particular reference to conditions of incu-

bation, and part 2 (pp. 272-274) studies on the effect of temperature on the sporulation time of *E. tenella*.

An acute infectious disease of pullets apparently caused by *Escherichia coli communis*, N. M. TWISSELMANN. (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 3, pp. 235, 236).—Report is made of a rapidly fatal disease that appeared in a group of 250 pullets at the University of California and from which *E. coli communis* was isolated. It is pointed out that this organism may not have been the sole causative agent in the outbreak.

The migration of the etiologic agent of fowl leukosis when subjected to electrophoresis, C. D. LEE and H. L. WILCKE. (Iowa State Col.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 3, pp. 178-186).—Work with fowl leukosis, the term used in common the group of transmissible, leukemic, aleukemic, and leukemiclike diseases of fowls, has shown that the disease in all its forms may be transmitted to healthy chicks by injections of cell-free filtrates. "The injection of a cell-free filtrate from one type apparently produces all of the various types considered as expressions of this disease, as neurolymphomatosis gallinarum, associated with eye lesions; hemocytoblastosis, lymphoid, erythroid, and myeloid leukosis were transmitted by a common etiologic agent. The behavior of the etiologic agent of fowl leukosis, when subjected to electrophoresis, is so like that of a virus that there seems little doubt that fowl leukosis is due to a filtrable virus. The etiologic agent of fowl leukosis migrates toward the negative pole at pH values of 4.01 to 6.01 and toward the positive pole at pH values of 7.01 and 9.01. The etiologic agent of fowl leukosis carries a positive charge between pH levels 4.01 to 6.01 and a negative charge from pH values 7.01 to 9.01. Protein tests show the etiologic agent was separated from its associated proteins by the electrophoretic method. The isoelectric point of the etiologic agent was found to be between pH values 6.01 and 7.01."

The inheritance of resistance to fowl paralysis (neurolymphomatosis), C. D. GORDON (*Alabama Sta. Rpt.* 1937, p. 24).—Data collected during the past 2 yr. are briefly noted.

Whole blood pullorum test studies, A. R. WINTER. (Ohio State Univ.). (*Poultry Sci.*, 18 (1939), No. 1, pp. 26-30).—Comparative data on the whole blood and tube pullorum tests are presented, together with information on the influence of time, temperature, agitation, serum, color of antigen, and ration on the results obtained with the whole blood pullorum test. There was found to be 99 percent agreement between the whole blood and tube test (1:50 dilution) on 5,867 birds where there was little pullorum infection. It is pointed out that this is not statistically significant because of the small number of positive birds involved. There was 87 percent agreement between the two tests in a group of birds which included many positive and doubtful birds. The higher the percentage of infection in a flock, the greater the percentage of disagreement that may be expected between the tube and whole blood tests. "The tube test detected a few birds with low agglutination titer not detected by the whole blood test. These birds are being subjected to further study. There was close agreement between the whole blood tests conducted at 40° F. and at 90°. The higher temperature reduced the time required for agglutination to take place. Rotation of the test plate after mixing the blood and antigen gave more reliable readings than when the plate was not rotated. More reliable results were obtained with a loop of whole blood than with a loop of serum in testing for pullorum with a stained antigen. Red antigen compared favorably with violet antigen when used in the whole blood test. Agglutination took place slightly quicker with the red antigen. The red antigen agglutination could be read more easily than the violet antigen agglutination in dim light. Feeding a heavy feed of wet mash containing

20 percent soybean oil meal 2 hr. before making the whole blood test did not interfere with the test."

The value of chemically-killed cultures for the control of cholera in ducks, K. F. HILBERT and H. TAX (*Cornell Vet.*, 28 (1938), No. 4, pp. 275-280).—Results of vaccinations of ducklings and breeder ducks against cholera are reported in detail in tables. On 4 ranches on which duck cholera was causing losses, 45,411 ducks and ducklings were vaccinated with a whole culture, phenol-killed bacterin and 5,761 birds, raised and fed with the others, were kept untreated as controls. The mortality from duck cholera averaged 4.1 percent in the vaccinated birds and 29.4 percent in the unvaccinated. It is concluded that the procedure is a means of controlling this disease even when the birds are kept under the insanitary conditions of the ordinary duck ranch.

The occurrence of papillomatous growths on the feet and legs of presumably iron-deficient turkeys, M. W. EMMEL (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 3, pp. 234, 235, fig. 1).

Infectious catarrhal enteritis of young turkeys, W. R. HINSHAW and E. McNEIL (Calif. Expt. Sta.). (*Nulaid Yeics*, 16 (1939), No. 11, pp. 25, 26).—In reporting on the catarrhal enteritis of young turkeys due to a diplozoic flagellate of the genus *Hexamita*, previously noted (E. S. R., 80, p. 688), the following measures are recommended as a means of prevention: (1) Selling all breeding birds at least 2 weeks before any poults are hatched; (2) complete isolation of the breeding unit from the brooding quarters; (3) separate attendants for the breeding flock and young poults; (4) use of cement yards, and wire pens; and (5) arrangement of feeding and watering equipment so that the attendant does not need to enter the pens.

The relationship of *Hexamita* sp. to an enteritis of turkey poults, W. R. HINSHAW, E. McNEIL, and C. A. KOFOD. (Univ. Calif.). (*Cornell Vet.*, 28 (1938), No. 4, pp. 281-293).—An investigation made of the relationship of a flagellate of the genus *Hexamita* to a catarrhal enteritis of turkey poults in California in connection with the studies noted above is reported. The disease has probably existed for many years, but due to increasingly congested conditions on turkey ranches it has become an increasingly important disease factor. It is State-wide in distribution, having been definitely diagnosed from Red Bluff in northern California to San Diego in southern California. This enteritis is principally confined to the duodenum and upper jejunum and is characterized by marked lack of tone, watery contents, distended bulbous areas, and a heavy infection of *Hexamita*. No other protozoa are present at the principal site of the pathology. The disease has been experimentally produced only when *Hexamita* has been present in the inoculum. *Trichomonas*, *Odontomastix*, and amebae have been definitely eliminated as the causative agent. Examinations of blood smears have not revealed any parasites, nor has any bacterium thus far studied been incriminated as the etiological agent.

An outbreak of pullorum disease in young guinea fowl, H. BUNYEA (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 3, pp. 233, 234).—Report is made of an outbreak of pullorum disease in Maryland which resulted in the loss of some 300 1-week-old guinea fowl in a flock to which it had spread from a brood of White Leghorn chicks. This is thought to be the first recorded occurrence of pullorum disease in the guinea fowl.

Trichomonas gallinae (Rivolta 1878) the correct name for the flagellate in the mouth, crop, and liver of the pigeon, R. M. STABLEY (*Jour. Parasitol.*, 24 (1938), No. 6, pp. 553, 554).

American vultures and the toxin of *Clostridium botulinum*, E. R. KALMBACH. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 3,

pp. 187-191).—A brief report is made of work conducted in continuation of that previously noted (E. S. R., 71, p. 705).

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Alabama Station, 1937], R. E. YODER, F. A. KUMMER, and E. G. DISEKER (*Alabama Sta. Rpt. 1937, pp. 7-9*).—Progress results are briefly reported of investigations on the physical effects of tillage as related to plant growth, development of reduced friction surfaces and materials for experimental plows, and the dynamics of soil erosion and the principles of control.

[Agricultural engineering investigations by the Iowa Station]. (Partly coop. U. S. D. A.). (*Iowa Sta. Rpt. 1938, pts. 1, pp. 45-51, 52, 120, 121; 2, pp. 19, 20, 21, 22, 23, figs. 4*).—In part 1, farm building losses due to wind and fire, atmospheric exposure tests of wire and fencing, utilization of plywood in farm building construction, utilization of steel in farm building construction, and utilization of lumber in farm building construction are reported on by H. Giese; basin method of treating pastures to prevent erosion, run-off, and loss of fertility, and design, development, and trial of a two-way terracing machine, both by E. V. Collins; moisture accumulation in farm building insulation, by H. J. Barre; and life, service, and cost of service of pneumatic tires for agricultural equipment as indicated by the experience of users, and efficiency and economy of pneumatic tires for transport wheels on agricultural equipment, both by E. G. McKibben. In hillculture studies, by J. M. Aikman and M. Donnelly, an improved pasture contour machine and a motor-driven rotary cultivator of foreign manufacture, the rotating tines of which loosen the soil to a depth of 8 in., were tested.

In part 2, trials of the basin method of planting corn on representative soil areas of the State are reported upon by J. B. Davidson, Collins, A. A. Bryan, and H. R. Meldrum; efficiency of corn pickers, and weed control in growing corn, both by C. K. Shedd, Davidson, and Collins; hill spacing of check planted corn, by Collins, Davidson, Shedd, H. D. Hughes, and Bryan; and storage and curing of corn, by H. J. Barre, Davidson, Robinson, W. R. Swanson, W. B. Combs, and P. E. Hoppe.

[Agricultural engineering investigations by the Oklahoma Station] (*Oklahoma Sta. [Blen.] Rpt. 1937-38, pp. 149-151*).—Tests of four types of sub-surface drainage for terraces have been made by L. E. Hazen, who also reports on four trials of electrically charged barbed wire for restraining various kinds of livestock, smooth wire having given results in the first test such that it was omitted from the remaining three trials.

[Agricultural engineering investigations by the Pennsylvania Station] (*Pennsylvania Sta. Bul. 367 (1938), pp. 13-15, figs. 2*).—Progress results are briefly presented of investigations on milk coolers, by J. E. Nicholas; improvements in potato cultivators and stone pickers, harvesting potatoes, and mechanics of tillage tools, all by A. W. Clyde; and electric fencing for livestock, by Nicholas and F. L. Bentley.

[Agricultural engineering investigations by the South Carolina Station]. (Partly coop. U. S. D. A.). (*South Carolina Sta. Rpt. 1938, pp. 89-94, figs. 3*).—Relative cost of labor and power in planting and cultivating corn when the size of the power unit varies is discussed by C. S. Patrick, and comparison of one-row horse-drawn combination cotton planters and fertilizer distributors by Patrick, G. B. Nutt, R. H. Jones, and E. E. Hall.

[Agricultural engineering investigations by the Texas Station] (*Texas Sta. Rpt. 1937*, pp. 152-156).—This work has included a study of mechanical harvesting of cotton, by H. P. Smith, D. T. Killough, and D. L. Jones; fertilizer placement and soil disturbance studies; treatment of cottonseed for planting purposes; planting of cottonseed at variable and uniform depths, including trials of the rubber press wheel and study of the width of furrow openers, and atmospheric exposure tests of wire and fencing, both by Smith; eradication of prickly pear, by W. H. Dameron and Smith; and garlic drying, by Smith and G. E. Alstatt.

[Agricultural engineering investigations by the Wisconsin Station] (*Wisconsin Sta. Bul. 442 (1938)*, pp. 26-31, 41-47, figs. 3).—Progress results are briefly presented of investigations on erosion control, by H. O. and D. Anderson, D. M. Keyes, and P. E. McNall (coop. U. S. D. A.); development of new equipment for making alfalfa silage, by F. W. Duffee and H. D. Bruhn, including a loop divider for a mower cutter bar, a hay harvester, and a new molasses pump; ventilation equipment for chopped hay, by Duffee, Bruhn, L. F. Graber, G. Bohstedt, B. H. Roche, and E. B. Hart; drying grain in windrows before combining, by Duffee and Bruhn; rotary sprinkler irrigation, by Duffee, Bruhn, and H. L. Ahlgren; and sealing of wells, by Duffee.

Surface water supply of the United States, 1937, parts 6, 7, 9 (*U. S. Geol. Survey, Water-Supply Papers 826 (1938)*, pp. VII+376, pl. 1; 827, pp. IV+173, pl. 1; 829, pp. V+197, pl. 1).—These papers present the results of measurements of flow made on streams during the year ended September 30, 1937, No. 826 covering the Missouri River Basin, No. 827 the lower Mississippi River Basin, and No. 829 the Colorado River Basin.

Problems of water resources for rice irrigation, D. G. CARTER and K. ENGLER (*Arkansas Sta. Bul. 371 (1939)*, pp. 31, pls. 2, figs. 13).—The investigation here reported upon has been confined to the Grand Prairie region, located mainly in three counties of Arkansas and covering most of the rice-producing area of the State. Most of the water is pumped from Pleistocene water-bearing sands but some is taken from deeper wells reaching Tertiary sands. Available data having indicated a decline in ground water level in the wells, the work here discussed was undertaken to determine the duty of water for rice and the ground water conditions and to study the problems arising from using surface supplies.

It was found that there were 37 relifts, 1,226 operating wells, and about 1,000 idle and abandoned wells in the Grand Prairie in 1937. Power plants include about 570 Diesel engines, 580 electric motors, and 75 spark-ignition engines. The average acreage irrigated was 87.8 acres per operating well in 1937. The total withdrawal of water in the Grand Prairie from 1905 through 1937 is estimated at 5,268,000 acre-ft. No estimate of total resulting decline of the ground water level could be made, but an 8-yr. study of complete yearly records from 38 typical wells indicated a continuous decline with a total of 6.39 ft. from 1929 to 1937. This decline was verified by measurements on 59 additional wells measured both in 1929 and 1937. Summary records for three Grand Prairie streams indicate a relatively large total annual run-off. However, there are many periods of "no flow," which occur principally during the irrigation season. Evaporation is the largest loss from reservoirs, amounting to 30 in. or more per year. Data for 1936 and 1937 indicate an average evaporation loss of 0.12 in. per day, which is somewhat less than the average rainfall for the area.

Calculations and prevailing practice indicate the most economical size for reservoirs to be from 250 to 650 acres, practical depths of from 6 to 7 ft.;

and from 10 to 12 ct. per cubic yard for reservoir levee construction. Nomo-graphic charts are included to afford a convenient method of solution for problems of duty of water and pumping.

The uses and possibilities of rubber in agriculture, A. HAY (*Brit. Rubber Pub. Assoc., Rubber and Agr. Ser. Bul. 8 (1938), pp. [1]+25, figs. 16*).—This is a compact summary of recent findings relating to the use of rubber in farm machinery, particularly as tires for drive and other transport wheels.

The evidence accumulated from various sources both in this country and abroad indicates that the use of the pneumatic tire for farm tractors and horse-drawn vehicles has led to greater efficiency in farm management. The deeper tread design of the farm tractor tire has proved more suitable for heavier soils and in areas of high rainfall. Larger-diameter tires are recommended for all but the smaller types of tractors. The use of the row-crop tractor with a narrow-section tire and a wheel of increased diameter has been very successful on mixed farms. Six- and eight-ply tires are recommended for agricultural tractors. Four-ply tires are only suitable for the lighter soils in areas of low rainfall. Wheel weights or water ballast are advisable as a means of overcoming slip. Antislip devices, including chains, strakes, or girdles, are necessary in areas of high rainfall and on heavy soils. Miscellaneous uses of rubber include horticultural equipment, grading machinery, grain drill tubes, sleeves for potato diggers, rubber blocks in the track construction of roadless tractors, and equipment for the eradication of bracken.

List of publications on the seasoning of wood. (Coop. Univ. Wis.). (*U. S. Dept. Agr., Forest Serv., Forest Prod. Lab., 1938, pp. [1]+20*)—This list includes publications that present the results of research of the Forest Products Laboratory on experimental and applied kiln drying, physical properties, air drying, and steam bending. It also contains a partial list of books on seasoning.

Mechanical properties of certain tropical woods, chiefly from South America, W. KYNOCH and N. A. NORMAN (*Mich. Univ., School Forestry and Conserv. Bul. 7 (1938), pp. 87, figs. 3*).—The results of tests on the mechanical properties of nearly 40 tropical woods are presented and discussed. The data, while not conclusive, indicate the probable value of these woods for industrial uses.

Experiments on toxicity, leaching, and fire-retarding effectiveness of Wolman salts, R. H. BAECHLER. (Coop. Univ. Wis.). (*U. S. Dept. Agr., Forest Serv., Forest Prod. Lab., 1938, pp. [1]+10, figs. 4*).—The author reports investigations on two preservatives called, respectively, "Tanalith" (sodium fluoride, sodium chromate, sodium arsenate, and dinitrophenol) and "Triolith" (sodium fluoride, potassium bichromate, and dinitrophenol).

The toxicity determinations showed that both are very toxic to six typical wood-destroying fungi and have adequate toxicity for wood-preserving purposes.

In the severe leaching tests, the chromium salts proved highly resistant, the total leached throughout the test being only about 1 percent. About one-fifth of the arsenate leached from the Tanalith treated blocks. The sodium fluoride leached out more rapidly and completely than the other salts, the average proportion leached falling between 70 and 80 percent of the amount originally injected. It was found that the leaching of sodium fluoride from Triolith treated blocks started at a slower rate than from similar blocks treated with sodium fluoride alone, although the total leached at the end of the test was approximately the same. When the leached blocks were exposed to fungus attack in Kolle flasks, it was found that the leaching had been carried so far that they were not immune to attack but, against all but one fungus, they showed much greater resistance than the untreated control blocks. The fungus

Lenzites trabea, known to be arsenic tolerant, attacked the leached Tanalith treated blocks about as severely as it did the untreated blocks.

Lumber treated with from 0.79 to 0.88 lb. of Wolman salts per cubic foot of wood showed no significant resistance to fire in the Forest Products Laboratory fire-tube test.

Studies on the use of bitumens in soil stabilization and flexible pavement types, E. W. KLINEBER (W. Va. Univ. Bul., 38 ser., No. 3-II (1937), pp. 128-133).—Laboratory tests of two types of low-cost road construction are reported upon. In the first, or penetration method, the road would be shaped, after which bitumen would be applied and allowed to penetrate. The second method would be a modified mix-in-place construction whereby the soil of the roadway would be loosened to a suitable depth, pulverized, mixed with bitumen, and compacted by roller and traffic. Results indicated that the modified mixed-in-place method should be the more satisfactory. In the penetration method the use of admixtures of calcium chloride, sodium silicate, ammonia, or soap solution to increase the depth of penetration or the speed of penetration did not appear advisable. Water alone gave results that compared favorably with any of the solutions.

The stability of mixtures made up from each of the three soils used with varied proportions of water and of the several bitumens was determined by means of the Hubbard-Field stability testing apparatus. After these determinations of the proper amounts of moisture and bitumen and the correct proportioning of aggregates in mixes, the Kriege testing machine was used to test the final mixtures. These were compared with tests made on other premixed materials with known field results.

Transition curves for highways, J. BARNETT (U. S. Dept. Agr., Bur. Pub. Roads, 1938, pp. [1]+211, figs. 7).—In this handbook the relation of speed to highway design is discussed, and a method for determining the required lengths of transitions under various conditions is presented, together with tables from which the required transitions can be chosen and located without extensive calculations. Other factors related to transitions, such as limiting curvature, superelevation, pavement widening, and right-of-way acquisition, are discussed.

Public Roads, [February 1939] (U. S. Dept. Agr., Pub. Roads, 19 (1939), No. 12, pp. [2]+225-243+[1], figs. 33).—This number of this publication contains data on the current status of various highway and grade-crossing projects receiving Federal funds as of January 31, 1939, and the following articles: Preliminary Results of Highway Capacity Studies, by O. K. Normann (pp. 225-232, 240); and Comparison of Methods for Determining the Hill Climbing Ability of Trucks, by C. C. Saal (pp. 233-239).

Field transport of cane on steel and rubber, L. A. THOMP (Brit. Rubber Pub. Assoc., Rubber and Agr. Ser. Bul. 9 (1939), pp. [1]+32, figs. 16).—The general trend of field transport of cane is subjected to detailed technical examination in this paper, with particular reference to the use of wheels equipped with steel and rubber tires. It is pointed out that a first condition for field transport is that the compactness of the soil must not be distorted, taking into consideration that the specific soil bearing is different under varying conditions of soil moisture—dry, medium dry, or wet. A second rule is to establish a practical limit to the soil bearing according to climatological conditions, i. e., the wheel or axle loads must be in relation to the wheel rim width, the wheel diameter, and the soil condition. On the basis that rim width is in direct proportion to the allowable wheel load, the conclusion is reached that the larger wheel diameter has a more solidifying action on the soil than the smaller one (less rut formation) for solid wheel tires, and the wheel load increases in

direct proportion to the rim width. It appears also that the caterpillar belt causes the lowest specific pressure on the soil of all rolling stock. The analysis indicates further that since the inflation pressure for pneumatic tires is related to the prevailing soil bearing, it follows that for hard paved roads the inflation pressure must be higher than for roads having less specific bearing capacity, i. e., for field roads.

Some things a farmer should know about electricity, H. L. GARVER (*Washington Sta. Pop. Bul. 157 (1939), pp. 40, figs. 19*).—The terms and materials in common use in general wiring work are defined and described, and elementary applications of Ohm's law are explained. Knob and tube wiring and the use of loom, sheathed cable, armored cable, and rigid metallic conduit are dealt with, and the conditions under which each may be suitable are indicated. Information sufficient to permit the work to pass inspection in the State of Washington is given. The wiring of burglar alarms, excess and deficient temperature alarms, and other warning and control devices are also taken up.

Attention is directed to the dangerous possibilities of electrified fences. Until more definite safety standards have been established, "the Washington committee on the relation of electricity to agriculture cannot recommend electric fences."

Air-blast gin performance and maintenance, A. J. JOHNSON and T. L. BAGETTE (*U. S. Dept. Agr. Circ. 510 (1938), pp. 18, figs. 10*).—Results obtained with air-blast ginning by nozzle pressures of 9, 12, and 15 in. in an extensive series of tests (on cottons ranging widely in moisture content, staple length, and other conditions and qualities) show that the quality of the lint, by classifications and laboratory measurements, was slightly damaged when the nozzle pressure was reduced from 12 to 9 in., in ginning damp or wet cotton.

The 9-in. pressure was less efficient and caused losses in gin turn-out of 4 lb. per bale on the damper cotton, as compared with the 12-in. pressure. For the drier cottons, the bale-value losses for the 9-in. pressure operation were smaller because of lower losses in bale weight and absence of noticeable damage to quality. On increasing the nozzle pressure from 12 to 15 in., a decline in bale value was noted for both damp and dry cotton.

Increasing the nozzle pressure from 9 to 12 in. by increasing the fan speed increased energy consumption 12 percent. It may be possible in some gins, by improvements and adequate repairs, to slow down the fans and actually save power, and at the same time provide sufficient pressure for efficient air-blast doffing. Correct air-blast pressure in a commercial gin can best be maintained by an intake valve on the fan. Gin nozzles should be given periodic attention to be sure that they are open so as to allow the free passage of air at a tangent to the gin saws. Air-blast nozzle-pressure gage and air-blast nozzle-setting and width gages are useful in operating air-blast gins economically.

Mechanical milk cooling on farms, J. R. MCCALMONT (*U. S. Dept. Agr., Farmers' Bul. 1818 (1938), pp. [2]+21, figs. 11*).—The results already given on mechanical refrigeration (*El. S. R., 73, p. 115*) are presented and discussed, with suggestions for effective arrangement and operation. Plans for an inexpensive home-made storage tank and a refrigerator box are also included.

Plans of farm buildings for Western States. (Coop. 11 State cols. and univs.). (*U. S. Dept. Agr., Misc. Pub. 319 (1939), pp. 120, figs. 125*).—The plans here partly illustrated, compiled by the Bureau of Agricultural Engineering and the Extension Service, cover farmhouses and barns of various types; live-stock shelters and related structural equipment; granaries and other storages; farm shops; machine sheds; garages; ice houses and other refrigerating struc-

tures; and processing and other special purpose buildings, including water storage structures, together with two forms of hay derrick.

Some engineering aspects of locker and home cold-storage plants, W. H. MARTIN (*Oreg. Engin. Expt. Sta. Circ. 4* (1938), pp. 18, figs. 5).—This is a discussion of the refrigerating plant and its adaptation to locker storage. Information also is given on a small combined freezer and storage.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Alabama Station 1937] (*Alabama Sta. Rpt. 1937*, pp. 6, 7).—Included are brief findings by B. T. Inman of the work stock purchases outside the State, 1929-36, and the commercial feeds sold in Alabama in 1936 and manufactured from State-grown products, and a table by B. F. Alvord showing by years 1929-35 the average income from farm production and the value of farm-produced-family-used products for farmers of the United States and Alabama.

[Investigations in agricultural economics by the Iowa Station, 1937-38] (*Iowa Sta. Rpt. 1938. pts. 1, pp. 187-203, 207-219, 220-226, figs. 5; 2, pp. 71-73*).—In addition to results previously noted, some findings are reported in part 1 as follows: (1) Brief statement by J. A. Hopkins, C. C. Culbertson, and H. R. Meldrum as to costs of producing feeder calves as shown in a study of the records of from 53 to 65 southern Iowa beef-producing farms from 1932-34, inclusive; (2) table with discussion by Hopkins and L. G. Allbaugh summarizing for the State and five type-of-farming areas data as to income, management return, capital, gross income per \$100 investment, gross value of crops per crop acre, livestock returns per \$100 feed fed, etc., as shown by 951 farm records for 1937; (3) brief summary by R. Schickele of the percentages of persons favoring different legislative proposals on tenure problems as shown by a questionnaire submitted at public county hearings; (4) brief statement by S. H. Thompson as to the decrease in number of livestock marketing cooperatives in Iowa and reasons therefor, and relative amounts of business of members and nonmembers in one association; (5) some findings by Hopkins, Allbaugh, R. K. Buck, and C. Y. Cannon as to crops grown, utilization of corn, farm incomes, livestock enterprises, butterfat production, labor returns on dairies, etc., based on records for 1935 and 1936 for 61 farms in northeastern Iowa; (6) some relationships between income and budgeted family living expenses of 1,136 Resettlement Administration families studied by M. G. Reid; (7) table and text by F. Robotka showing the number of farm marketing, purchasing, service, and credit and insurance corporations in the State, capital, membership, volume of business, etc.; (8) a discussion by C. M. Elkinton of the probable effects of wage-hour legislation on rural farm commodity marketing agencies, with tables and charts showing the percentages of employees working 60 hr. or more per week and receiving less than 40 ct. per hour; (9) table showing the U. S. tariff rates ad valorem in 1932 (0-25 percent, 26-50 percent, 51-75 percent, and 76-100 percent) on items entering into farm production and living costs, and chart for 1929 showing the proportion and value of exports to the British market of important agricultural products from the Corn and Cotton Belts, and the grain and fruit areas of the United States, by T. W. Schultz; (10) some preliminary findings by Schultz as to the changes in and flexibility of farmers' production expenditures 1929-36; (11) some findings by G. S. Shepherd, M. D. Helser, and F. J. Beard as to differences in the value of different grade carcasses and the accuracy of the present live weight basis for buying hogs; (12) brief general findings by I. W. Arthur in a study of public regulation of livestock marketing;

(13) some findings by W. W. Wilcox and W. D. Goodsell as to the effects of the Tama County and North Central Regional Adjustment programs in 1937; (14) brief discussion by Allbaugh of the economic significance and possibility of substituting hay and pasture crops for intertilled and small grain crops in the Corn Belt; (15) findings by Hopkins, Allbaugh, J. B. Davidson, and A. B. Caine as to the average cost of keeping a horse, hours' work per horse, etc., on horse-operated farms in 1936-37, per hour cost of operation of one-, two-, and three-plow general-purpose tractors, relative costs of standard and pneumatic tire tractors, number of hours of man labor, and drawbar horsepower hours required to produce an acre of corn to harvest on general-purpose tractor and horse-operated farms; (16) some facts as to grading methods, weight, and quality classes used by poultry buyers, attitude of marketing agencies regarding uniform grades, etc., in a study by A. D. Oderkirk; (17) findings by P. Quintus and Robotka as to volume of business, percentage of cream grading as sweet cream, charges for hauling, total mileage of cream routes, etc., in a study of cooperative creameries in Butler County; and (18) tables by Schultz, A. C. Bunce, Allbaugh, Schickele, Wilcox, and C. A. Anderson showing the changes in crop areas on 73 farms in the southern pasture area of the State cooperating with the Soil Conservation Service, and a comparison of the land use in 1937 by cooperators and noncooperators. Also included are some findings in statistical investigations by G. W. Snedecor, G. M. Cox, and A. E. Brandt on the validity of applying analysis of variance to data arising from the radiation of virus exposed to X-rays for various periods of time, and of yield response of different varieties of oats to early and late planting.

Part 2 includes brief discussions by Robotka and R. C. Bentley of findings in studies of grain handling methods and grain merchandising practices of farmers' elevators and by Shepherd on corn loans as related to corn crop adjustments.

[Investigations in agricultural economics and farm management by the Cornell Station 1937-38] (*New York*] *Cornell Sta. Rpt. 1938*, pp. 72-79, 160).—In addition to findings previously noted, brief general statements are made as to findings by L. Spencer in studies of milk distribution by 92 producer-retailers and of the surplus-milk problem in the New York milkshed, by W. Powell in a study of the factors affecting the costs of cooperative farm fire insurance, and by E. V. Hardenburg and P. J. Findlen on market quality of potatoes sold in city markets.

[Investigations in agricultural economics by the Oklahoma Station 1936-38] (*Oklahoma Sta. [Blen.] Rpt. 1937-38*, pp. 16-38, figs. 6).—Tenancy as a factor in the agricultural conservation program of the State is discussed by P. Nelson, with a map showing the relation of farm tenancy to mineral resources of the State, and a table showing the land use, income, degree of erosion, and slope of land on farms operated by owners, part-owners, and tenants in Kiowa and Muskogee Counties. Using results of a 9-yr. study of wheat farming in Garfield County, the problem of wheat v. livestock is discussed with tables by Nelson showing data as to the average investment, size of farm, acreages and yields of wheat, percentages of total returns from livestock, and labor income on the farm studied by years 1929-37, and the organization and financial returns of the 10 most and the 10 least profitable farms by years 1930-37. Based on an analysis of the price movements of 24 Oklahoma farm commodities 1910-37 by T. R. Hedges, the factors responsible for the price movements of different types of commodities and the effects of sudden price changes are discussed. Some of the findings of A. L. Larson in studies of cooperative marketing made in cooperation with the U. S. Farm Credit Administra-

tion and the Oklahoma extension division are discussed. Tables show the dates of organization of cooperative elevators by periods, the average total sales by years 1926-36, and the gross income, expenses, and net gain in 1933 of such elevators grouped by the amounts of total sales. The method used by R. T. Klemme in preparing a land-ownership map for the State is described, and the uses of such a map illustrated. For a study of the effects of quality, volume, and distance from market on the value of cottonseed by K. C. Davis, charts are included showing by weeks 1937-38 (1) the Dallas prices for prime seed and the volumes sold by and prices paid to farmers, and (2) the cottonseed prices paid farmers and cottonseed meal and cottonseed oil prices. The effect of different factors in the price movements of cottonseed are briefly discussed. Using data gathered by Hedges in a study of the relationship of quality of cotton to prices received in local markets, the conditions in Oklahoma and the factors responsible for the lack of close relationship between price and quality are described and suggestions made as to means by which the relationship may be improved. Charts show the relationship between premiums and discounts for different staple lengths and different grades in local and central markets.

[Investigations in agricultural economics at the Pennsylvania Station 1937-38] (*Pennsylvania Sta. Bul.* 367 (1938), pp. 11, 12).—Included in addition to those previously noted are brief findings by J. E. McCord in a study of farm leases and tenancy and as to labor income, investment, receipts and expenses, crops, numbers of livestock, etc., in Centre County as shown by 1,262 farm records for the years 1931-37.

[Investigations in agricultural economics by the South Carolina Station 1937-38]. (Partly coop. U. S. D. A. et al.). (*South Carolina Sta. Rpt.* 1938, pp. 15-26, figs. 3).—Results of studies are reported as follows: (1) Findings by H. A. White and W. T. Ferrier as to changes in average staple length of cotton produced in the State 1928-36, (2) preliminary findings as to sources and types of loans, interest rates, etc., in the study of short-term credit, by Ferrier, (3) data as to farm mortgage recordings and interest rates, as to size and assessed value of taxable farm properties, as to trends of real estate taxes per acre, as to amount of real estate taxes delinquent 1928-37, and as to relation of sales prices and assessed values of farm real estate, by G. H. Aull and E. Riley, and (4) brief general findings by Aull in studies of taxation and the ability to pay as measured by net income, of the effects that might be expected from homestead tax exemptions, and the factors influencing the location of industrial plants in South Carolina.

[Investigations in farm and ranch economics at the Texas Station 1936-37] (*Texas Sta. Rpt.* 1937, pp. 123-131).—Included in addition to findings previously noted are (1) a brief statement by C. A. Bonnen, B. H. Thibodeaux (U. S. D. A.), and A. C. Magee showing average acreage in farm and acreage cropped, variation in returns to labor and management, and cotton yields per acre, etc., on 70 to 141 farms in the high plains cotton area studied from 1931 to 1936, and tables showing changes in numbers of tractors and work stock 1931 to 1937 and the significance of the changes from the standpoint of their possible effects on number and size of farms; (2) brief findings by W. E. Paulson in a study of quality as a factor in marketing vegetables in the lower Rio Grande Valley; (3) the correlations between test weight and protein content 1931-34 of wheat samples collected and studied by Paulson, G. S. Fraps, and R. T. Stewart of central and local market prices of wheat in relation to quality in the Panhandle area; (4) some findings as to methods of computing patronage dividends used by cooperative cotton gins and the effects of the

use of each method on dividends by L. P. Gabbard and Paulson as a part of a study of operating costs and financial conditions of gins in Texas in cooperation with the U. S. Farm Credit Administration; and (5) some findings by Gabbard and C. H. Hamilton relative to the income of tenants and owners, changes in the leasing systems, etc., in a study of the economic significance of different farm leasing systems in Texas.

[Investigations in agricultural economics by the Wisconsin Station 1937-38]. (Partly coop. U. S. D. A.). (*Wisconsin Sta. Bul.* 442 (1938), pp. 3-26, figs. 8).—Findings are included in the following studies: (1) Summary of the proportions of the consumers' dollar spent for fluid milk chargeable to payments to farmers, wages, salaries, depreciation, profit, and other items as found in the study by W. P. Mortenson, L. Witt, and C. Heisig of 13 Wisconsin dairy farms 1927-36; (2) data on proportion of total milk handled by large dairy plants as found in a study by A. W. Colebank, R. K. Froker, and A. C. Hoffman; (3) chart showing weekly sales of three kinds of cheese during the 2 weeks before, the week of, and the 2 weeks following a sales campaign as found in a study of records of 29 Louisville, Ky., stores for May-June 1938, by A. Hobson and M. A. Schaars; (4) the relation between factory price of cheese at the Plymouth market and average retail price in 51 cities 1919-32 found in a study by D. Anderson; (5) findings as to the reasons for the high level of tenancy in Wisconsin based on a study in Iowa County, by J. L. Spaulding, G. S. Wehrwein, and G. W. Hill; (6) brief statement of why tenants gained by renting large farms based on a study of 627 farm records for 1936, by B. H. Hibbard and P. E. McNall; (7) findings as to fixed charges per \$1 of receipts, acre of cropland, and head of livestock on 20 farms having the highest and lowest incomes of 100 farms studied for 1935, by D. R. Mitchell and Anderson; (8) costs per acre, labor used, etc., for sugar beets on 52 farms studied in 1937, by McNall; (9) table based on study of H. H. Bakken and M. Beal showing the cost of producing beet sugar by three Wisconsin companies in 1933, 1934, and 1935; (10) findings by Anderson, and W. H. Ebling, W. H. Bormuth, and F. J. Graham of the Wisconsin Crop and Livestock Reporting Service as to organization of farm enterprises by owners and tenants, changes in percentage receipts of milk and milk equivalent of cream at Wisconsin dairy plants 1929 to 1936, seed production in Wisconsin in 1935, and changes in farm population in Wisconsin; (11) trends of butterfat production 1926-36 on 48 farms studied by Anderson and Mitchell; (12) some findings in the study by Hibbard and K. H. Parsons of the effect of the Wisconsin system of State aid for schools on property taxes paid by farmers, and (13) findings as to the location, method of operation, rental charges, benefits to farmers and city families, etc., of cold storage locker plants in a study by Schaars.

Landlord and tenant income in Colorado, R. T. BURDICK (*Colorado Sta. Bul.* 451 (1938), pp. 54, figs. 17).—Analysis is made of tenant farm records obtained in the Greeley-Fort Collins area for the years 1922-35 to show the causes of variation in income and to determine the effects of prices, yields, and methods of leasing. The customary farm leases in other areas in Colorado are described. A proposed form for Colorado farm leases is included.

The tenant farms included in the study had an average of 141 acres in crops. The actual average yearly farm income 1922-35 was \$1,603.62 for the tenants and \$1,111.30 for the landlords. Tenants failed to have an income in 2 of the 14 yr. On a representative farm selected for detailed study the average farm incomes for the 14 yr. were tenant \$2,479.28 and landlord \$1,735.64. The tenant had no income in 5 of the years. Winter feeding of sheep and cattle added approximately \$685.66 per year to the tenant's net cash income

and \$267.37 to the landlord's income. Winter feeding benefited the tenant in 8 yr. and resulted in a loss in 6 yr. If the usual Corn Belt fifty-fifty lease had been substituted for the original lease on the representative farm, the average incomes from crops would have been tenant \$900.53 and landlord \$2,361.36 as compared with \$1,793.62 and \$1,468.27, respectively, under the original lease.

The tenants' variable expenses for potatoes and sugar beets were comparatively heavy, and consequently the landlords could survive lower crop yields or lower prices without a minus income. With barley and alfalfa the fixed costs of the landlords were relatively heavier, and the tenants could have survived lower yields. Farms of 160 acres were necessary if the tenant were to have a reasonable chance to have sufficient income to permit a down payment on a farm. Tenant farms in the area had better yields than owner farms, indicating that tenancy in the area operates under favorable conditions.

The trend in sale prices of farm real estate in Minnesota, A. A. DOWELL (*Minnesota Sta. Bul. 338 (1938), pp. 24, figs. 4*).—The average sale prices by 2-yr. periods 1910-11 to 1936-37 are shown by counties for the southeast, southwest, east central, west central, northwest, and northeast districts of the State and the State as a whole. Other tables and charts show the index numbers of the prices (1912-13=100) for the districts and the State. The factors favorable and unfavorable to an increase in farm land values and the possibilities of stabilizing such values by different methods are discussed. The data for 1910-11 to 1928-29 are based on county records of actual transactions obtained by the Minnesota Tax Commission, those for 1930-31 being supplemented by sales made by various lending agencies. For 1932-33 through 1936-37 reports of sales by corporate agencies—insurance and trust companies, land banks, and the State of Minnesota Department of Rural Credit—made direct to the division of agricultural economics of the station were used.

The average sale value of farm real estate advanced from \$41 per acre in 1910-11 to \$82 in 1918-19 and to \$104 in 1920-21, then decreased from \$85 in 1922-23 to \$60 in 1930-31, to \$45 in 1932-33, and was \$40 and \$39, respectively, in 1934-35 and 1936-37. The trends in each of the six districts were upward to 1920-21, with a pronounced decline following, but the rate of increase and rate and duration of the subsequent decline varied greatly from district to district. The decline was checked in the northeastern and northwestern districts in 1932-33 and in the southwestern district in 1934-35. In the other three districts the decline continued through 1936-37, but was much less pronounced in the southwestern district than in the two central districts.

Capacity to pay and farm financing, L. J. NORTON, J. ACKERMAN, and C. R. SAYRE (*Illinois Sta. Bul. 449 (1938), pp. 173-224, fig. 1*).—This study of capacity of farmers to pay indebtedness is based on summaries of 1935 accounts kept by 1,055 cooperating farmers, of which 348 were owner-operators, 278 part owners, and 429 tenants. The sources of credit, types of security given, and interest rates are discussed. Analysis is made by tenure groups of debts and cash income, debts and capital, acres operated and value per acre, the influence of debts on working capital, and agencies financing different groups. The adjusting of financing plans to capacity to pay, land ownership and capacity to pay, the desirability of debt repayment, capital and capacity to pay, and a program for farmers with limited capital are discussed.

The average apparent capacities in 1935 to pay debts for all debt ratio groups in the less than \$1,000 net income group were owners —\$607, part owners —\$407, and tenants —\$242. In the \$1,000-\$1,999 net income group they were \$166, \$299, and \$461, respectively. In the \$2,000 or more group they were \$1,732, \$1,992, and \$1,713, respectively. In the high income group the debts

of owners averaged about 6 times the yearly capacity to pay, those of part owners 4 times, and those of tenants 0.4 times. In the middle income group the debts of owners were 38 times the capacity to pay, those of part owners 14 times, and those of tenants 1.4 times. In the low income group there was no capacity in any tenure group "In mortgage lending, according to this analysis, three plans involving different lengths of time for retiring debts are needed in order to fit a loan to the capacity of the borrower to pay it: Amortization in 10 yr. or less—for farmers having high capacity to pay and light debts. Amortization in 20 to 25 yr.—for farmers having high capacity to pay and heavy debts. Amortization in 35 to 40 yr.—for farmers having low or medium capacity to pay and heavy debts."

Montana farm foreclosures: Number, characteristics, and causes of farm mortgage foreclosures over a seventy-year period, with some suggestions for reducing them in the future, B. R. RENNE (*Montana Sta. Bul.* 368 (1939), pp. 58, figs. 28).—Analysis is made of the number, characteristics, and causes of foreclosures during the period January 1, 1870, to January 1, 1938. The farm credit problem of the State is discussed. Number and trend of foreclosures are discussed, and comparisons made with neighboring States and the United States. Some suggestions are made for securing more satisfactory farm credit practices. The foreclosure procedure in the State is briefly described.

During the period 1870-1938 nearly 34,000 real estate mortgages involving 11 million acres and \$75,000,000 were foreclosed. There were 20,244 foreclosures during the period 1921-25, 6,598 during the period 1926-30, and 3,359 during the period 1931-37. The total claims—loan, interest, taxes, court fees, etc.—exceeded \$100,000,000. Less than 6 percent of the total claims remained unsatisfied after foreclosure sales. Deficiency judgments were taken in about four-fifths of the cases where deficiencies remained. The foreclosed loans averaged $1\frac{1}{2}$ times and the total claims nearly 2 times the productivity value of the lands as compared with less than two-thirds of the productivity value for all mortgaged farms. Resident individuals and resident agencies made loans corresponding more closely with productivity values than did other loaning agencies. Short-term loans (5 to 10 yr.), loans bearing over 6 percent, and straight-term loans were the least successful. Total claims averaged over $2\frac{1}{2}$ times the amount loaned in the case of loans of less than \$250, and less than $1\frac{1}{10}$ times for loans of \$10,000 or over.

"Farm foreclosures can be reduced by (1) basing loans on the productivity value of the lands as determined by a scientific soil survey and average yields and prices, (2) adjusting annual loan repayments to current income and in terms of buying power rather than dollars, (3) effecting a strong credit education program to familiarize borrowers and lenders with the consequences of unwise credit practices and the permanent advantages to be secured from more scientific lending policies, and (4) incorporating improved farm management and land utilization practices in farm mortgage contracts."

An economic study of farming in the Crooked Creek area, Indiana and Armstrong Counties, Pennsylvania, D. H. WALTER (Coop. U. S. D. A.). (*Pennsylvania Sta. Bul.* 369 (1938), pp. [2]+42, figs. 9).—The area studied is one in which a demonstration project for practical erosion control was begun by the U. S. D. A. Soil Conservation Service in 1934. Usable survey records for 344 full-time farms were obtained for the year beginning April 1, 1934, before the program was started, and for 148 farms for the year beginning April 1, 1936. The second survey included 55 cooperators and 93 noncooperators in the conservation program. The area is described. Using the data from the first survey, analysis is made of land uses, numbers of livestock, types of farming, farm income, tenancy, crop and livestock production practices, the factors affecting

labor income, etc. The problems of soil conservation, contemplated changes under the program, changes accomplished, and the possible effect of the program on production are discussed. Some of the findings were: From 25 to 75 percent of the original top soil had been lost from 49.8 percent of the total farm land, and over 75 percent on 19.2 percent of the land. The gross receipts per farm averaged \$1,150, of which 47.4 percent came from dairying, 73.7 percent from all livestock, and 13.8 percent from crops. The average labor income was —\$119. On 41 of the 344 farms it was from —\$600 to —\$1,000, on 186 from —\$1 to —\$599, on 92 farms from 0 to \$599, and on 25 farms from \$600 to over \$1,000. The average for owner-operators was —\$114, for part-owners —\$127, and for tenants —\$125. Number of animal units, crop yields, livestock production, and efficiency of man labor were four important factors affecting labor income. The average labor incomes with none to all of these factors above the average were: No factor —\$332, one factor —\$243, two factors —\$111, three factors 0, and all four factors \$304. The average size of farm was 122.2 acres, of which 58.8 acres were in crops, 17.5 in woods, 28.5 in pasture, and 17.4 acres in "other land," mostly idle or abandoned. The agreement of 55 farmers cooperating with the Soil Conservation Service called for an average increase of 6.2 in crops, 5.9 in new forest plantings, and 3.8 acres in permanent pastures, and a decrease of 13.4 acres in other land. Most of the change in land use from 1934 to 1936 was in rearrangement of field boundaries and contour farming rather than in acreage.

Farm organization by land class on the Eastern Highland Rim, C. E. ALLRED and A. C. ROBISON (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 89* (1939), pp. III+28, figs. 11).—Tables are included and discussed showing by land classes the distribution of farms, major land uses, size of farms, investment, sources of receipts, current expenses, sources of farm labor, etc., and the relations to land class of man-equivalents and man-work units per farm, crops, livestock, diversity index, farm expenses, outside employment of operator, tenure of operators, etc. The data covered 131 farms and were secured in a farm management survey in Overton County, based on the 1936 crop year.

A study of farm organization by types of farms in Uinta Basin, Utah, G. T. BLANCH (*Utah Sta. Bul. 285* (1939), pp. 91, figs. 10).—The location, history, topography, climate, soils, irrigation water supply, transportation facilities, markets, timber and other resources, economic and social conditions, land ownership, utilization of public grazing lands, etc., are discussed. Analyses are made of 285 detailed farm records for 1935 obtained in the reservation area, and 103 obtained in the Ashley Valley area.

The average labor incomes on the different types of farms and ranches in the reservation area were: General —\$155, dairy —\$21, mixed livestock —\$6, beef —\$119, sheep \$840, and part-time —\$202. In the Ashley Valley they were \$6, \$24, \$963, \$554, \$288, and —\$139, respectively. In addition, the value of farm privileges ranged from less than \$250 for the part-time farms to nearly \$500 for the range livestock farms. The important factors affecting the financial success of the farms were type of farming, rates of production (including crop yields, percentage lamb crop, percentage calf crop, wool per sheep, and pounds butterfat per cow), death loss of livestock, size of farm business, and efficiency in the use of man-labor. The most successful farms were better than average in several of these factors. Average number of man-days of labor available but not needed on the farms ranged from 118 on beef ranches to 221 on general farms and 231 on part-time farms in the reser-

vation area, and from 7 to 79 on sheep, beef, and mixed livestock ranches to 133 to 181 on dairy, part-time, and general farms in the Ashley Valley.

Some trends in Utah's agriculture, W. U. FUHRMAN (*Utah Sta. Bul.* 286 (1939), pp. 30, figs. 9).—Weighted index numbers were computed for crop and livestock yields and intensity, combined yields and intensity, size of farms, and production. The period 1926–31 was used as the base for the index numbers.

Acreages harvested increased until about 1920, remained fairly constant 1920–33, decreased in 1934 during the drought, then increased, but were about 4 percent less in 1937 than the 1926–31 average. The trend in the number of productive animal units per farm was generally upward until about 1931. There was a marked decrease in 1935, and since that time the number has been 5 to 10 percent below the 1926–31 average. Intensity of crop production increased about 15 percent from 1910–20, decreasing about 15 percent in the next decade, and in recent years has been only slightly above 1910. Intensity of livestock production increased from 91 in 1920 to 101 in 1929 and 105 in 1935 and 1936 (1937=103). The trend of crop yields was sharply upward until 1905, after which crop yields fluctuated rather widely, the fluctuations coinciding to a marked degree with fluctuations in precipitation. Yields from 1931 to 1937 were lower than in any period of like length in 50 yr. The trend in yields of livestock products per animal was generally upward until about 1926. Since that date it has been fairly constant except for the low year 1932. The trend of total production of crop and livestock products was upward until the late twenties. Since 1930 it has been about 14 percent below that of the previous 7 yr. The average cash income for crops and livestock 1931–37 was only 60 percent of that of the preceding 7 yr. The number of farms increased 18 percent 1925–35. The average production and cash income per farm for the period 1931–37 were 76 and 53 percent, respectively, of those for the preceding 7 yr.

Part-time farming in the United States: A selected list of references, compiled by H. E. HENNEBRUND (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.* 77 (1939), pp. VI+272).—Included are 777 references to materials on part-time farming and subsistence homesteads in the United States published from approximately 1900 through October 1938. References to marginal or subsistence farming by full-time farmers, the Little Landers' Movement in California, farm laborers' allotments, garden cities and greenbelt communities, and war time gardens for increased production are omitted. The first 342 items are general references. The remainder are grouped by States.

Costs and returns in producing potatoes in central Maine, W. E. SCHRUMPF (*Maine Sta. Bul.* 392 (1938), pp. [3]+34, figs. 4).—An analysis is made of the costs of production and disposal of the potato crops harvested in 1929 and 1930 on central Maine farms and of the effects on the costs and returns of such factors as size of potato enterprise, yields, labor efficiency, etc. The data were obtained by personal visits to the producers of table potatoes on 38 farms. A method of estimating the cost of growing and harvesting potatoes where different prices prevail for labor, seed, fertilizer, etc., is presented.

Relatively large acreages tended to be associated with relatively low costs of production per acre and relatively high yields with high costs of production per acre and low cost per barrel. Selling costs per barrel varied with the amount of potatoes sold. The average cost of production on the farms studied was \$110.28 per acre or \$1.15 per barrel, of which about 40 percent was for fertilizers, 34 percent for labor, power, and equipment, and 13 percent for

seed. The average cost of harvesting was \$16.85 per acre or 17.4 ct. per barrel, of which about 93 percent was for labor, power, and equipment. Costs of storage averaged about 26 ct. per barrel harvested and 33.8 ct. per barrel stored. Selling costs averaged 8.5 ct. per barrel harvested and 9.9 ct. per barrel sold. Farms above the average in acres of potatoes, yields of potatoes per acre, and acres of potatoes per man returned an average net income of 95 ct. per barrel as compared with 67 ct. per barrel for all the farms.

The tobacco industry: A selected list of references on the economic aspects of the industry, 1932-June 1938, compiled by L. O. BEBOW (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.* 75 (1938), pp. VIII+337).—Included are 1,205 references to books, pamphlets, and periodical articles on the economic aspects of the leaf and manufactured tobacco industry in the United States and foreign countries published from 1932 through the first half of 1938.

References are included on the agricultural adjustment and control programs for leaf tobacco of the U. S. Department of Agriculture, and on cost of production, credit, grading, standardization, inspection, labor, legislation, marketing, price, statistics, taxation, advertising, sales campaigns, and the financial standing of tobacco companies, as well as on labor problems, taxation, and other aspects of the manufactured products industry. The section on the United States (references 1-801) contains two parts, one on leaf tobacco classified by subjects with sections on Puerto Rico and the Philippine Islands, and one on tobacco products classified by subjects. The references to foreign countries are grouped by countries, and while not complete, an attempt was made to include the more outstanding references to foreign publications in the libraries of the U. S. Departments of Agriculture and Commerce and the Library of Congress. References are not included on diseases and pests, physiological aspects, chemical aspects (except a few on tobacco curing), and technical processes of manufacturing tobacco products.

The peach enterprise in western New York: Soil relationships, costs and returns, and marketing, H. F. DEGRAFF (*[New York] Cornell Sta. Bul.* 710 (1939), pp. 37, figs. 6).—Using data on yields and changes in number of bearing trees for 160 orchards in Newfane Township, Niagara County, 1926-36, obtained in a series of farm-management surveys, the relation of three groups of soils to yields and mortality of trees are discussed. Based on data obtained in 1936 for 120 orchards 4 yr. or older on 52 farms in Porter Township, Niagara County, analysis is made of the costs of growing peaches to harvesting by types of expenditures and operations, of costs for harvesting, packing, and marketing, and returns per acre, bushel, and hours of labor. Using data on marketing peaches obtained from growers in Newfane Township for 1936 and from Porter Township growers for 1936 and 1937, the grading, packing, and storing of peaches, the types of buyers, sales outlets, etc., are discussed.

The average yield per tree 1926-36 on the shallowest and poorest drained soil group was 0.68 bu. as compared with 1.13 bu. on the deepest and best drained soil group, and 0.86 bu. on the intermediate group. Only two-thirds of the trees remained on the poorest soil group at 7 yr. of age. On the best soil group two-thirds still remained at 20 yr. of age. For both yields and mortality the soil differences showed up most markedly after 5 or 6 yr. The average cost for the Porter Township orchards up to harvest in 1936 was \$53.96 per acre and 44.8 ct. per bushel, of which labor comprised 32 percent, materials 20 percent, taxes, interest, and orchard depreciation 33 percent, power 9 percent, equipment 5 percent, and miscellaneous expenses 1 percent. The cost of harvesting, packing, and marketing averaged 22.5 ct. per bushel. Credit

for culls sold amounted to 25 ct. per acre or 0.2 ct. per bushel. The average net returns were \$52.61 per acre, 41 ct. per bushel, and 89 ct. per hour of labor.

Marketing fruits and vegetables on farmers' markets, New York Metropolitan District, M. P. RASMUSSEN ([*New York*] *Cornell Sta. Bul.* 709 (1938), pp. 60, figs. 28).—This study was made as a part of that on the use of motortrucks in marketing fruits and vegetables (*E. S. R.*, 79, p. 411). Data were gathered during the summer of 1934 from 267 growers who sold fruits and vegetables chiefly on the Harlem, Wallabout, and Gansevoort farmers' markets. The places of origin and disposal of produce, size of farms, gross sales, commodities sold, seasonal movement of produce, types of containers used, fees incident to use of the markets, the opinions of growers concerning operations of a market, and the marketing problems of the markets are discussed.

Approximately 89 percent of the produce sold by these growers was marketed on farmers' markets in New York City, and of this approximately 34 percent was sold to hucksters, 33 percent to jobbers, 32 percent to independent retailers, and 1 percent to chain stores. The average cost of operating 283 farm trucks was 8.7 ct. per mile, or 8.3 ct. per mile per ton of fruits and vegetables. "In the opinion of these growers, increased use of the motortruck has had little, if any, effect on grading practices. About 36 percent of the growers thought use of the motortruck had resulted in lowered prices, but one-fifth thought the opposite, and 43 percent had been unable to observe any effect." The gross sales price per ton on the three farmers' markets was about \$2.90 higher than that in the wholesale markets on Washington Street, and net returns to growers were about \$1.11 per ton higher. Average costs of marketing were \$11.40 per ton on the Washington Street market and \$7.36 on the farmers' markets, the major differences being \$2.56 per ton for containers and 90 ct. lower selling costs. Costs of marketing per ton did not necessarily increase with distance, because larger loads were usually hauled in the case of longer distances. As size of average load increased, costs per ton for transportation and selling declined, but cost of containers remained about the same. The usual expense per trip incurred by growers exclusive of transportation and services of growers' family or hired labor in selling was \$5.60 to \$6.50. The average time per trip to market was 19 hr. and 32 min.

"The major problems on these markets seem to be: To improve the quality of salesmanship on the market; to work out some means of obtaining a reasonably accurate knowledge of available supplies daily before trading starts; to develop sound economic grade standards, which buyers are able and willing to pay for and which growers can meet at reasonable cost; to standardize offerings as to weight within reasonable limits; and to reduce costs of marketing. It may be possible for growers to attain a higher quality of salesmanship by the following procedures: By hiring special marketmen who are recognized as good salesmen; by groups of growers selecting one of their number who has the required qualifications to sell the output of the group; by establishing a cooperative (farmer-owned and controlled) sales agency on each farmers' market; by establishing an auction system of selling on each farmers' market; [and] by making more complete use of professional salesmen, such as commission merchants, brokers, and the like."

Methods and costs of marketing potatoes in Pennsylvania, W. R. WHITACRE (*Pennsylvania Sta. Bul.* 372 (1939), pp. [2]–25, figs. 7).—The location and nature of the potato industry in Pennsylvania, varieties grown, types of markets and marketing methods, and the direct and indirect competition with other States are described. Using data furnished by cooperative marketing groups

in Somerset, Indiana, and Butler Counties, detailed analyses were made on the costs of marketing and the relation of such costs to net returns for approximately 82,800 bu. of potatoes in the 1936-37 season. Some data are also included as to costs and net returns for potatoes marketed through cooperative groups in Lancaster and Potter Counties, and costs of selling potatoes at the farm, in local markets, and in city markets in Bucks, Lehigh, and Schuylkill Counties.

The data indicate that if the policy of cooperative groups of placing sales emphasis on U. S. No. 1, 2-in. minimum grade, is continued, there is relatively little opportunity to lower market costs per bushel. Bag, transportation, and grader costs are to a large degree constant. Labor costs were not directly correlated with quality. Cost of sacks was the chief item varying with quality. Grading facilities and predominating type of defects influenced labor costs more seriously than total percentage of defective potatoes. Costs of marketing in the cooperative groups studied ranged from 10.8 to 31.6 ct. per bushel during the 1936-37 season, generally being 21 or 22 ct. Net returns per bushel in general increased proportionately with increases in marketing costs.

Livestock shipping associations, A. A. DOWELL and S. T. WARRINGTON (*Minnesota Sta. Bul.* 339 (1938), pp. 24, figs. 7).—The developments in the cooperative shipping movement through 1936 are briefly reviewed. Data as to organization and operation of associations in Minnesota in 1936, obtained from officers in a field survey in the summer of 1937, are analyzed. Analysis is also made of the factors responsible for the changes in the number of associations, number of members, volume of business, etc. The more important problems confronting individual producers in marketing livestock and possible methods of assisting them are discussed.

The number of associations in Minnesota decreased from 655 in 1919 to 520 in 1931 and to 262 in 1936, the number of members decreased from 124,000 to 45,000, and the volume of business handled from 61 percent of livestock marketed by Minnesota farmers to 13 percent. Of the associations in 1936 nearly 29 percent had fewer than 100 members each and 78 percent less than 225 members. Approximately 20 percent shipped less than 1,200 head of livestock, and 80 percent less than 4,800. Approximately 63 percent of the livestock shipped was sold to cooperative commission companies, 14 percent to private commission companies, and nearly 23 percent direct to packers. The increase of mileage of hard-surfaced roads and the number and efficiency of motortrucks, improved grade standards, and availability of market news resulted in many producers dropping out of associations. "If local associations are to meet the requirements of farmers in many parts of the State, they must be organized as marketing rather than as forwarding associations. To insure adequate volume to justify the expense of a capable manager, office and yard force, adequate equipment, and keeping in touch with the available outlets, the association should have 500 to 1,000 or more members."

Organization and management of the Falls Cities Cooperative Milk Producers' Association, J. B. ROBERTS and H. B. PRICE (*Kentucky Sta. Bul.* 390 (1939), pp. 37-87, figs. 13).—This bulletin describes the organization of the Falls Cities Cooperative Milk Producers' Association, the chief representative of milk producers in the Louisville milk market, reviews the experiences of the association, and points out the problems encountered and the methods used by the association in solving specific problems. It is based on information and data secured from the records of the association, the Louisville milk market administrator, the city health department, and through interviews with the management of the association, 281 farmers (about 20 percent of all shippers of graded milk), and about two-thirds of the dealers in the market. The his-

tory and plan of organization of the association are described. The plans used in selling milk, prices of market milk, the price policy for different classes of milk, other phases of the price problem, the surplus problem and adjusting supply to demand, hauling of milk, the service activities of the association, the financing and the operating costs of the association, and the membership relations are discussed.

Report on the agricultural implement and machinery industry.—I, Concentration and competitive methods. II, Costs, prices, and profits (*U. S. House Represent., 75. Cong., 3. Sess., Doc. 702 (1938), pp. XXI+1176, [figs.] 17, maps 3*).—This is a report, including conclusions and recommendations, of the Federal Trade Commission on the agricultural implement and machinery industry. Part 1 (pp. 1-390) "deals with the economic factors upon which the production and distribution of farm implements and machines is based, the history of developments by which the bulk of production and wholesale distribution both in domestic and foreign trade has become concentrated in the hands of a few large manufacturing companies, the extent of concentration of production by such companies, the nature of distribution organizations and agencies by which implements and machines are sold, the factory equipment and programs of operations of typical manufacturing plants, and competitive methods and practices pursued by both manufacturers and dealers, with special attention to methods and practices which may involve restraint of trade or tend to produce further concentration of control or monopoly in production and distribution." Part 2 (pp. 393-1038) deals with "the investments and profits of farm implement and machinery manufacturers, their varying costs of production for a variety of products, the prices received by manufacturers and dealers, the prices at which machines are sold in foreign markets, a comparison of the movement of the prices of farm machinery with the movement of the prices of other comparable commodities, and the investments and profits of retailers of farm implements and machines."

Agricultural relief measures relating to the raising of farm prices.—Seventy-fifth Congress, January 5, 1937 to June 16, 1938, compiled by M. E. WHEELER and M. I. HERB (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog. 76 (1939), pp. 1+109*).—This is a companion list to those previously noted for the Seventieth, Seventy-first, and Seventy-second Congresses (*E. S. R., 74, p. 871*). The bills are classified under the major agricultural relief plans considered in the Seventy-fifth Congress. Extracts from the Congressional hearings on the bills are included.

Agricultural price control in foreign countries: Some outstanding examples (*U. S. Dept. Agr., Foreign Agr. Serv., Foreign Agr., 3 (1939), No. 2, pp. 43-83*).—"This article describes some of the more important developments in the field of agricultural price control in foreign countries and attempts to evaluate the results thus far achieved, from the standpoint of the consumer as well as of the producer." The countries considered are Germany, Italy, Japan, Argentina, Australia, Canada, Denmark, France, the Netherlands, New Zealand, and the United Kingdom.

Trend of farm prices in N. D., W. O. BROWN (*North Dakota Sta. Bimo. Bul., 1 (1939), No. 3, pp. 5-7, figs. 2*).—Charts show for the period 1910-38 (*E. S. R., 62, p. 783*) index numbers (1910-14=100) of prices received by farmers in North Dakota for farm products (combined index 14 commodities), and paid by farmers in the United States for commodities used in production and family maintenance and of the purchasing power of North Dakota farm products. The index numbers for individual products for 1938 were: Wheat 77, rye 60, oats 54, barley 61, flax 96, potatoes 66, sheep 74, butterfat 97, eggs 87, cattle 127, hogs 104, lambs 119, wool 110, and chickens 117 percent.

[Oregon cash farm income] (*Oregon Sta. Circ.* 130 (1938), p. 47, fig. 1).—A map shows the total cash income from certain specialty farm products by type-of-farming districts of the State.

Crops and Markets [January–February 1939] (*U. S. Dept. Agr., Crops and Markets*, 16 (1939), Nos. 1, pp. 24, figs. 3; 2, pp. 25–48, figs. 3).—Included are reports, tables, summaries, charts, etc., covering crops, livestock, farm prices, farm labor, farm wages, etc., and market reports on cotton, dairy and poultry products, feeds, seeds, grains, and livestock and livestock products. No. 1 includes an article on cash farm income in 1938, with tables showing for 1937 and 1938 the cash income by crops and groups of livestock and livestock products and from Government payments, and by States the cash income from crops, livestock and livestock products, and Government payments.

Deciduous fruit statistics as of January, 1939, compiled by S. W. SHEAR (*California Sta. Mimeog. Rpt.* 66 (1939), pp. [74]).—This is a compilation of statistics as to State and national acreages, production, exports, imports, consumption, farm value, utilization, etc., of different deciduous fruits. Included are 13 general tables, 3 tables on plums, 4 each on dates and prunes, 5 each on apples, apricots, and cherries, 7 on peaches, 8 on figs, 9 on pears, and 10 on grapes.

RURAL SOCIOLOGY

[Investigations in rural sociology by the Iowa Station] (*Iowa Sta. Rpt.* 1938, pt. 1, pp. 204–207).—Topics discussed are an estimate of the farm population and movement to and from farms in Iowa (coop. U. S. D. A.), and the characteristics of persons receiving public and private old-age assistance in Iowa, both by R. E. Wakeley.

[Investigations in rural sociology by the Cornell Station] (*[New York] Cornell Sta. Rpt.* 1936, pp. 155, 156).—Subjects reported upon include a survey of rural churches in Cortland County, by H. E. Hammer; and organization and uses of rural-community buildings in New York State, by W. M. Smith, Jr.

[Investigations in rural sociology by the Oklahoma Station] (*Oklahoma Sta. [Bien.] Rpt.* 1937–38, pp. 145–148).—Topics discussed are the cityward movement of rural population, farming for unemployed miners, and effects of land-ownership on the farmer and his family.

[Investigations in rural sociology by the South Carolina Station] (*South Carolina Sta. Rpt.* 1938, pp. 10–15, fig. 1).—Among the subjects discussed are social mobility in the farming occupation, by B. O. Williams; social educational relationships, by H. L. Fulmer, G. H. Aull, and Williams; and studies in farm tenancy, by Williams and Aull (coop. U. S. D. A.).

[Investigations in rural sociology by the Wisconsin Station, 1938] (*Wisconsin Sta. Bul.* 442 (1938), pp. 31–34, fig. 1).—Subjects discussed are nationality groups, by G. W. Hill and G. S. Wehrwein, and unemployables on relief, by Hill and R. A. Smith (both coop. Works Progress Administration).

Low-income farms in West Virginia: A symposium (*West Virginia Sta. Mimeog. Circ.* 32 (1938), pp. [1]–44, fig. 1).—Included are the following papers: Implications of Low-Income Farm Families to State and Local Governments, by C. R. Orton (pp. 1, 2); Income From Agriculture and Relief to Farmers in West Virginia (pp. 3, 4) and Tax Payments of Farm Families Receiving Relief in Monongalia County Compared With Relief Expenditures (pp. 9, 10), both by W. W. Armentrout; Extent of Relief to Farm People in West Virginia, by A. W. Garnett (pp. 5, 6); Extent of Work Relief to Farm People in West Virginia, by J. N. Alderson (pp. 7, 8); The Extent to Which the West Virginia Agricultural Extension Service Reaches Low-Income Farmers of the State, by J. O.

Knapp (pp. 10-15); Assistance of Farm Security Administration to West Virginia Low-Income Farmers, by R. G. Ellyson (pp. 15-19), and What the Soil Conservation Service is Doing for Low-Income Farms, by L. L. Lough (p. 20) (both U. S. D. A.); The State Department of Agriculture, by J. B. McLaughlin (p. 21); The Agricultural Conservation Program and Low-Income Farms, by C. E. Stockdale (pp. 21, 22); and Opportunities Suggested by Staff Members of the Agricultural Extension Service and of the Agricultural Experiment Station for Aiding Low-Income Farms to Obtain a Larger Income (pp. 23-35). An appendix is also included.

Social problems in agriculture (*Internat. Labor Off., Genève, Studies and Rpts., Ser. K, No. 14* (1938), pp. IV+162).—This publication is a record of the Permanent Agricultural Committee of the International Labor Office and includes reports prepared by the International Labor Office concerning agricultural labor, debates at the first session of the Permanent Agricultural Committee, and the report of the Committee, including general discussion of agricultural labor, the standard of living and economic conditions in agriculture, the protection of the agricultural worker, and other questions.

Problems of rural life focused by the depression, D. SANDERSON. (Cornell Univ.). (*Rural Sociol.*, 3 (1938), No. 3, pp. 258-266).—The depression has affected rural life mostly on the economic side, but has given a larger place to the subsistence values of rural life, as well as impetus to soil conservation. County organization of rural social work, direct attack on the tenancy problem, and a strong movement for Federal aid to the common schools are other movements resulting from the depression. Farmers have become convinced of the necessity of collective action, but it has also become apparent that their interests are regional and that the integration of the opposing interests of different regions is essential for a national policy for agriculture.

Business cycles and age of operators as factors in the progress of Tennessee farmers, C. E. ALLED and E. E. BRINER (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 87* (1938), pp. [I]+III+30, figs. 12).—This monograph discusses the accumulation of wealth by farm operators as influenced by economic cycles and age of the operator on the basis of 457 schedules secured in three counties representing the livestock, dark-fired tobacco, and cotton areas of the State. Unusually high prices during the World War period were accompanied by greater accumulations of wealth by farm operators of all tenures than during any other period covered by this study. Farm operators normally accumulate more per year after passing middle age, due to returns on capital saved and to smaller demands for family living. White and colored inheriting operators are similar in their patterns of wealth accumulation, but colored operators accumulate less than white operators. Owners were able to accumulate more than tenants in all periods considered in this study. Wealth accumulation by white inheriting owners is probably responsible to a large extent for the difference in current net worth existing between inheriting and noninheriting operators, between colored and white operators, and between owners and tenants.

Tenure by type of farming areas and color in Tennessee, C. E. ALLED and E. E. BRINER (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 85* (1938), pp. [I]+II+24, figs. 15).—This study indicates that tenancy in Tennessee increased from 34.5 percent in 1880 to 46.2 percent in 1935, chiefly in west and middle Tennessee. There is no apparent race distinction based on tenure of farm operators. Concentration of tenants is associated with high labor-requiring cash crops, particularly cotton and tobacco. Colored croppers are concentrated in about the same localities as cotton, except those located in the

dark tobacco area. White croppers are widely distributed over the State, being somewhat fewer than colored croppers in the most intensive cotton area of southwestern Tennessee. Croppers operate land of the highest per acre value.

Inheritance as a factor in the progress of Tennessee farmers, C. E. ALLRED and E. E. BRENER (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog.* 58 (1938), pp. [1]+1V+35, figs. 24).—The authors discuss the effect of inheritance on farm ownership and on tenure and wealth accumulation as revealed in studies in Madison, Montgomery, and Williamson Counties.

Of all operators studied, 44.4 percent had received an inheritance before the time of taking the record, and an additional 5.6 percent will yet inherit, making inheritance an important factor in the farm business of 53 percent of all cases. Of the owners, 64.2 percent had inherited compared with 21.3 percent of the tenants. This difference is due partly to age and partly to color. Of white operators, 55.1 percent had inherited compared with 18.7 percent of colored operators. The greater proportion of persons inheriting (57.8 percent) were 35 yr. of age and under. The average inheritance was about \$1,000. The rate at which wealth was accumulated varied between tenure classes, between white and colored, between inheriting and noninheriting operators, and between counties. Lower tenure groups had a larger proportion of noninheriting than inheriting operators. Higher tenure groups were nearly equal in percentage of inheriting and noninheriting operators, except unencumbered owners of whom there were approximately 2.5 who had inherited to 1 noninheriting. Lower tenure groups contained more colored operators and fewer who had at one time been owners. Noninheriting operators spent more years in the lower tenures than inheriting operators. Nonfarm years in the operator's experience served as an important wealth-accumulating period. However, over half the net wealth accumulated during these years was from inheritance. More frequent and greater losses were reported while engaged in nonfarm pursuits. Inheritance appears to be an important factor in the return to the farm of families after engaging in nonfarm occupations.

State reforestation in two New York counties: The story of the land and the people, T. E. LAMONT ([New York] *Cornell Sta. Bul.* 712 (1939), pp. 23, figs. 3).—This is a report of a study of persons who had sold land to the State in Chenango and Madison Counties, which shows how little social disturbance is created by a well-organized, unhurried, long-time purchase program. Of 363 parcels sold to the State before June 1935, 335 were in reforestation areas, and 28 in the Pharsalia Game Refuge. The average size of parcel was 140 acres. About 65 percent of the land sold was cleared. An average of 6 yr. elapsed from the time of moving from the farms sold to the time of selling the land to the State. Only 14 percent of the parcels sold to the State were occupied at the time sold, 8 percent by owners, 5 percent by tenants, and 1 percent by persons using the house only as a residence. Only 17 percent of the parcels sold were operated during the year before State purchase; 40 percent had been idle for 10 yr. or more.

In reforestation areas one-third of the parcels sold never had any house, and on these the house or barn was gone or falling on 61 percent. On only 21 percent did the former owners consider both the house and barn fair or good.

Of all those who sold land to the State in these areas only 6 percent said they would repurchase if given the opportunity, and only 3 percent said that they were worse off because of selling the land.

Social aspects of farm labor in the South, H. HOFFSOMMER. (La. State Univ.). (*Rural Sociol.*, 3 (1938), No. 4, pp. 434-445).—Farm labor in the South

comprises four major groups—(1) unpaid family workers; (2) year-round workers, including sharecroppers; (3) seasonal workers; and (4) migratory workers. As compared with the nation the Southeast has proportionately more unpaid family workers, more hired laborers when sharecroppers are included, greater seasonal variation in demand due to the one-crop system, and relatively few migratory laborers. The Southeast is also characterized by a dense agricultural population, a greater proportion of the gainfully employed in agriculture than elsewhere in the country, and a large amount of female agricultural labor, while the historical background of labor in the Southeast and the fact that 40 percent of the present agricultural laborers are Negro profoundly influences the whole structure of labor relations. The many problems involved are not subject to ready solution but must be comprehended in view of a planned agriculture, which should include labor as an integral part of the agricultural structure.

Social aspects of farm labor in the Pacific States, P. H. LANDIS. (Wash. State Col.). (*Rural Sociol.*, 3 (1938), No. 4, pp. 421-433).—In the Pacific Coast States, which have long been accustomed to seasonal labor not only in agriculture but in lumbering and fishing, transient farm labor has become a problem of major proportions. Social legislation designed to underwrite the risks of the socially inadequate embraces chiefly the urban-industrial classes, even though the farm laborer on the West Coast has long been subject to as much exploitation and as much uncertainty in his mode of life as has any urban-industrial group. A highly unstable agricultural industry is not able to carry full responsibility for the security of farm laborers. Therefore, programs designed to stabilize agriculture should ultimately effect an improvement in the lot of the laborer. There is said to be room for a great deal of improvement in the social and economic conditions of the various types of agricultural workers, conditions which not only endanger health and general welfare but also threaten the West's reputation for social equality. Among the important gestures of groups interested in problems of farm labor are two recent measures of the U. S. D. A. Farm Security Administration—a socialized health program for the lower strata in agriculture in California, and the development, on an experimental basis, of a chain of sanitary farm labor camps up and down the coast, both of these programs being financed chiefly by the Federal Government.

Constructive measures for dealing with the South's population problems, C. C. TAYLOR. (U. S. D. A.). (*Rural Sociol.*, 3 (1938), No. 3, pp. 239-257, figs. 8).—The four general types of adjustment suggested are the promotion of balanced farming or a maximum development of live-at-home farming, the expansion of manufacturing processes of many kinds, the encouragement of combined farming and industrial enterprises, and the intelligent guidance of the relocation of surplus population into both farming and industrial enterprises.

Depopulation of Louisiana's Sugar Bowl, T. L. SMITH. (La. State Univ.). (*Jour. Farm. Econ.*, 20 (1938), No. 2, pp. 503-509).—The serious social consequences brought about by a depression in the sugarcane industry because of mosaic disease and other complicating factors are discussed. Although new varieties of cane were developed which were more resistant to disease and insects which preyed upon the sugarcane borer were discovered, propagated, and disseminated, much social wreckage resulted from the depression in the industry. Abandoned plantations and cabins; dismantled sugar houses; fertile and well-located lands out of cultivation; decadent towns, villages, and hamlets; business enterprises closed out, bankrupt, or in straitened circumstances; and

schools and churches struggling to maintain a semblance of their functions indicated the social effects better than statistics of production.

The depressed agriculture of the area has continued to employ about the same number of white people, and the towns and small cities in the area have absorbed part of their natural increase. Colored laborers on cane plantations, however, were left without employment, and the net result was that both urban and rural Negroes were forced to leave the cane area. The extent of their removal, 32 percent between 1910 and 1930, marks the extent of the depopulation in this region, as the white population gained 1.8 percent. It is expected that these Negro laborers will form the bulk of the re-employment with a revival of the sugar industry.

The possibility of a distinctive culture contribution from the American Negro, T. G. STANDING. (Okla. A. and M. Col.). (*Social Forces*, 17 (1938), No. 1, pp. 99-106).—"Since emancipation there has developed a small but none the less significant middle class, and the proportion of educated persons within the group is rapidly increasing. Illiteracy has been reduced from 81.4 percent in 1870 to 16.3 percent in 1930. It is estimated that from 1826 to 1936 more than 43,000 Negroes have graduated from colleges and professional schools. This includes some 150 recipients of the Ph. D. degree. Since 1870 the value of property owned by Negroes has increased from \$20,000,000 to \$2,500,000,000. . . . Analysis of census data indicates an increasing degree of occupational diversification among Negroes. This trend has been especially pronounced during recent decades, although partially interrupted by the current depression."

Recent shifts in Negro occupations indicate the potential ability of the colored masses to succeed in occupations other than those assigned them by tradition, and this in turn tends to refute the assumption that the Negro is destined by nature to a limited or specialized cultural role. Notwithstanding a widespread belief to the contrary, it is by no means certain that a disproportionate number of American Negroes have achieved distinction in the artistic and literary fields. According to *The Negro Year Book* there are 12 Negroes listed in *American Men of Science*. Of the 100 included in the 1936-37 edition of *Who's Who in America* the majority are clergymen, and only 5 represent what could properly be termed artistic pursuits. Relatively few colored persons have become outstanding in business, industry, or science, but there are enough exceptions to indicate that lack of ability in these lines is not a racial trait.

In view of the wide diversity of the Negro's chief contributions to date, there is reason for distrusting the theory that his cultural choices are determined by a peculiar racial temperament. Negro groups and communities, especially in urban areas, are noted where the institutional forms are indistinguishable from those of the whites. Racial prejudice and segregation have had the effect of throwing the Negro more and more upon his own resources and as a result he is developing a racial consciousness and a corresponding sense of racial pride and self respect. Since Negroes and whites seem destined to live together for an indefinite period, the author concludes that it would be extremely unfortunate if such a development should obscure their fundamental identity of interests.

The composition of rural households, W. A. ANDERSON ([*New York*] *Cornell Sta. Bul.* 713 (1939), pp. 24, figs. 4).—This study describes the composition of the rural households of Genesee County, N. Y. The sample includes 2,925 households, about 80 percent of all households in the open-country area of the county. Of these households, one-half are composed of husband, wife, and children, and one-sixth include only husband and wife. One in 8 consists of a

married couple, children, and other persons, and 1 in 10 is a broken family household of 1 parent with children and other persons. In addition, in 1 of each 30 households no marital ties exist between the household members, and 1 in 40 is constituted only of an unmarried man or woman.

Human and physical resources of Tennessee.—XXXIII, County government. XXXIV, Municipal government, C. E. ALLRED, S. W. ATKINS, and L. P. BOHANAN (*Tenn. Agr. Col., Agr. Econ. and Rural Sociol. Monog. 86* (1938). pp. [I]+VI+524-555, figs. 15).—In Tennessee the county is an administrative unit of the State and a unit of local self government, performing functions that are of both State and local concern. In 1935 there were 71 Tennessee counties with less than \$10,000,000 assessed valuation. Over 90 percent of the tax revenue came from the general property tax while 82 percent of nontax revenues came from State and Federal funds. Forty-three percent of total expenditures by county governments was for schools in 1932, but more money is spent for interest on indebtedness than for outlays. Total indebtedness of all Tennessee counties increased from \$16,521,000 in 1912 to \$104,322,000 in 1932.

There are three types of municipal government in Tennessee—mayor-council, commission, and city-manager. Cities and towns have only those powers delegated to them by the State legislature. Per capita receipts and expenditures of municipal governments tend to increase directly as the population of the unit increases. Ninety percent of tax revenue for municipal government is raised from property tax. Towns and cities in Tennessee had an average net debt of \$115 per capita in 1932.

Rural community patterns of social participation, O. F. LARSON. (Colo. State Col.). (*Social Forces, 16* (1938), No. 3, pp. 385-388).—A survey of seven representative Minnesota town-country communities was made in the fall of 1934 by interview of a random sample of 1,350 out-of-school persons 15 yr. of age and over, 100 from each village center in all cases but one, where half as many were secured, and 100 from the open country service area of each village. The average monthly attendance was secured for participation in formally organized group activities, following with slight deviation the classification of major types used by Brunner and Kolb (*E. S. R., 69*, p. 299).

The data imply a need for demanding an elastic and individualized community treatment rather than an iron-clad blanket application of procedures and policies as conceived by some centralized authority. About one in six of the sample population did not attend any form of organized activity as frequently as an average of once a month. A smaller proportion of farm people than villagers participated in each type of activity, and farm people had only 62 percent as great a total volume of attendance as village people. More males than females participated in athletic and socio-economic activities, while the reverse was found for educational, social, and socio-religious affairs. Activities associated with institutionalized religion dominated organized participation in rural communities, accounting for 71 percent of all attendances. Such activity was more important for farm than village people, being 83 and 63 percent, respectively, of all contacts. Younger people were more active participants than their elders. Persons aged from 15 to 34 yr. had about 10 percent more participation than "expected," while the groups 35 and over had less than "expected," with the difference steadily increasing until the group 65 and over had almost 15 percent less attendance than would be assumed from their proportion in the sample population.

Criteria of rural community formation, D. SANDERSON. (Cornell Univ.). (*Rural Sociol., 3* (1938), No. 4, pp. 373-384).—The rural community is an emer-

gent sociological concept. The use of the rural community as the school attendance unit will tend to institutionalize it. Rural school consolidation may seriously impair rural community life if based solely on so-called efficiency. Four criteria for the areas of rural communities are advanced as a means for obtaining constructive discussion. These are based on the ideas of relative self-sufficiency, opportunity for personal association, and pooling of resources for desired institutions. The development of such standards and the mapping of rural communities is an important function of State and county planning boards and should be made a feature of the county land use planning committees being established by the agricultural extension services.

Diagnosing rural community organization, D. ENSMINGER. (Cornell Univ.). (*Rural Sociol.*, 3 (1938), No. 4, pp. 410-420).—The individuality of a rural community may be characterized according to (1) village-farm relationships as being adolescent, mature, or debilitated; (2) degree of organization as being underorganized, overorganized, or disorganized; (3) organizational interaction as being circumscribed, conflictive, or cooperative; (4) assimilative character of a community as being efficient or inefficient; (5) community self-sufficiency as being inadequate, partial, or adequate; (6) leadership as being personal, positional, or organizational; (7) community self-identification as being geographical distinction, history and tradition, competition or conflict with other communities or outside pressures, or divided loyalties; and (8) community activities and events as being community supported activities, activities without community interest, or interest and activities lacking.

Status of research pertaining to situations and problems among rural young people, E. L. KIRKPATRICK (Washington, D. C.: *Amer. Youth Comm., Amer. Council Ed.*, 1938, pp. [2]+12).—"One-fourth of the experiment stations have studies underway. Most of these apply specifically to older youth, while others are in the field of population migration or rural relief but give secondary attention to young people and their problems."

Taking stock of rural youth, B. L. MELVIN and E. N. SMITH (*Social Forces*, 17 (1938), No. 2, pp. 167-174).—"The future of American rural life . . . rests on increased industrial production, a closer integration of industry and agriculture, and an expansion of the cultural and human services so badly needed in rural society."

Our present knowledge of assortative mating, C. A. ANDERSON. (Iowa State Col.). (*Rural Sociol.*, 3 (1938), No. 3, pp. 296-302).—Assortative mating is said to deserve inclusion in research projects on the family. Evidence is summarized to support the hypothesis that "free choice" leads to mating of like with like for all those criteria of choice which have been studied. The type of selectivity involved in friendships and other intimate associations strengthens this hypothesis. The factors in actual matings which facilitate or hinder this analytically abstract tendency are discussed. These modifications reveal many essential features of the family and of the society studied.

Human and physical resources of Tennessee.—XXIX, Health. XXX, Welfare work, C. E. ALLEED, S. W. ATKINS, and R. G. MILK (*Tenn. Agr. Col., Agr. Econ. and Rural Sociol. Dept. Monog.* 83 (1938), pp. [1]+VII+458-495, figs. 12).—The authors show that the annual cost of medical care in Tennessee exceeds \$24 per capita. The State has a growing population, births exceeding deaths by 7.7 births per 1,000 population. Whites have a higher birth rate than Negroes, the latter being actually on the decrease. There were 461 fewer physicians in 1938 than in 1923. In 1937 there were 3,000 persons per dentist for the State, but in 9 counties this number was 20,000 persons per dentist, and there were no dentists in 8 counties. There were 97 hospitals in 1937,

providing the State with 5.2 hospital beds per 1,000 people. This was the sixth lowest figure in the country and considerably below the United States average of 8.7 beds per 1,000 people. The amount spent per capita for health and sanitation work by the State and local governments in 1936 amounted to 46 ct. and was exceeded by 45 States.

The characteristics and mobility of rural physicians: A study of six Wisconsin counties, H. MASLOW (*Rural Sociol.*, 3 (1938), No. 3, pp. 267-278).—In the area selected, during a 24-yr. period the population changed but little, but the number of physicians in proportion to the population decreased by 23 percent, this resulting from a movement of 203 physicians into the area, 156 out, and 82 deaths or retirements. An average mobility rate of over 11 percent a year was found. The mobility rate was greater in the older age groups and in the smaller communities. A considerable number of physicians were graduates of low-grade medical schools, but the proportion of these substantially decreased during the period. The trend from 1912 to 1936 was toward an older average age. Over half of the physicians moving into the area during this period were not recent graduates but came from other places of practice—about two-thirds coming from rural places (under 2,500 population) and only about one-third from cities. Of the recent graduates who moved into the area between 1912 and 1936, a higher percentage eventually moved away than remained.

Rural housing problem in the South, S. H. HOBBS, JR. (Univ. N. C.). (*Rural Sociol.*, 3 (1938), No. 3, pp. 279-295).—Chief factors responsible for the long-standing rural housing problem in the South are climate, farm income, high Negro ratios, farm tenancy, and small farms. This problem has received scanty attention, and much pessimism exists as to possibilities of remedying rural housing conditions, especially for low-income farm groups. The main suggestions are to subsidize housing for low-income groups, extend Federal Housing Administration into rural fields, carry on work begun by the Resettlement Administration, expand the program of the U. S. D. A. Farm Security Administration, and encourage self-help among farmers themselves through educational programs and otherwise. The author thinks that a modification of the plan whereby some 60,000 cottages were erected for farm laborers in Ireland could be employed as a partial solution.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Building rural leadership (*U. S. Dept. Agr., Ext. Serv.*, 1939, pp. 76).—This is a report of the extension work in agriculture and home economics in 1935. The assistance to the A. A. A., the new fields of work, the activities with crops, the improvement of flocks and herds, farm engineering activities, the work with homemakers in 4-H Clubs, the work with Negroes in adjusting farm and home practices and in 4-H Clubs, and the work on extension education through motion pictures, short courses, demonstrations, radio broadcasts, charts, etc., are described. An appendix includes statistics as to results of the work, and the work with boys and girls by projects and by States by projects as to expenditures from Federal appropriations and from funds within the States. The data for results are for the year ended November 30, 1935, and those for appropriations for the fiscal year ended June 30, 1935.

4-H Club work: Effect on capability and personal quality, D. E. LINDSTROM and W. M. DAWSON (*Illinois Sta. Bul.* 451 (1939), pp. 273-343, figs. 10).—Using the same group of 2,263 boys and girls as in a previously noted (E. S. R., 76, p. 269) study on factors influencing 4-H Club membership, the increase in capability resulting from 4-H Club work was studied. This increase was especially

noticeable among the boys who had taken no agriculture in high school but who had carried on beef, sheep, or corn 4-H Club projects and among the girls who had not had home economics in high school. Interest in the possibilities of farming and farm life was associated with achievement, and members of 4-H Clubs, both boys and girls, had in general a more appreciative attitude toward farm life than nonmembers. Members of 4-H Clubs, both boys and girls, gave indications of having greater social-mindedness and more leadership ability than nonmembers, but it was not possible to determine whether the difference was due to 4-H Club training or to selectivity.

Scoring judging contests, H. S. BRUNSER (*Pennsylvania Sta. Bul.* 367 (1938), p. 57).—The correlations between final placings and total scores found in a study of reliability of the judging contest score card now in use are given and commented on.

FOODS—HUMAN NUTRITION

[Nutrition studies by the Alabama Station] (*Alabama Sta. Rpt.* 1937, pp. 20-23, fig. 1).—Progress reports (E. S. R., 78, p. 580) are given on studies by W. D. Salmon on the relation of unsaturated oils and fatty acids to rat acrodynia or vitamin B₁ deficiency; by C. O. Prickett, Salmon, and G. A. Schrader on the peripheral nerves in acute and chronic vitamin B₁ deficiency; and by W. C. Sherman on the carotene content of green and mature soybeans and cowpeas and on the effect of oils on the utilization of carotene by rats.

[Studies in foods and nutrition by the Iowa Station] (*Iowa Sta. Rpt.* 1938, pt. 1, pp. 62-65, 122, 155-162, fig. 1).—The work covered by these progress reports, for the most part representing an extension of earlier work (E. S. R., 79, p. 560), includes field and cooking trials on 46 varieties of vegetable soybeans and 4 standard varieties of field soybeans, by C. P. Wilsie, P. M. Nelson, and B. Lowe (pp. 62-65); tests for the inactivating action on vitamin A in butterfat by various edible oils, the antioxidant effect of thymol on open-kettle lard, Mazola, and soybean oil, and the effect of various treatments on the inactivating power toward vitamin A of Mazola, by V. E. and P. M. Nelson and Lowe (p. 122); studies on the nature of the dietary deficiency causing progressive retardation of growth in successive generations of rats, the biological value of autoclaved pork muscle, dietary factors in the production and cure of toxemic pregnancies induced by the feeding of certain pork diets, and the lactagogue factor in liver and beef muscle, by P. Swanson and P. M. Nelson (pp. 155-159); certain phases of the cooperative project on the nutritional status of college women as related to their dietary habits, including the standardization of technics for measuring red cell volume and hemoglobin, a study of the basal metabolism data on freshmen and sophomore students, scores of food intake records of freshmen and upperclassmen students, and a continuation of the long-time balance study of a single subject, by P. M. Nelson and M. A. Ohlson (pp. 159-161); and the effect on palatability and tenderness of poultry of different chilling and freezing treatments, by P. M. Nelson, Lowe, and Wilsie (pp. 161, 162).

[Foods and nutrition studies by the Maine Station] (*Maine Sta. Bul.* 391 (1938), pp. 261-267, 287, 288, 320, 321).—These progress reports (E. S. R., 79, p. 129) summarize an extension of the investigation on food habits and nutritional status of children in selected communities in Maine, by M. M. Clayton (pp. 261-263); on the relation of man and animals to the environment, including an experimental and economic analysis of food getting, by W. F. Dove, and the selection of genetic strains of fruits and vegetables high in mineral and vitamin content, by E. F. Murphy and Dove (pp. 263-267); and

on cooking quality of potatoes, including cooking tests on the relation of net necrosis to cooking quality in general, by M. D. Sweetman (pp. 287, 288). A summary is also given of a study by J. McIntosh on factors affecting the vitamin C content of tomatoes and rutabagas (pp. 320, 321).

[Nutrition studies in Pennsylvania] (*Pennsylvania Sta. Bul.* 367 (1938), pp. 6, 7, 45, 46, fig. 1).—Notes are given on work by R. A. Dutcher and N. B. Guerrant on the loss of vitamin A in Cheddar cheese during curing and the curative value of yeast concentrates, determinations by A. K. Anderson of the hemoglobin and red cell content of blood and of the effect of dried yeast on the uric acid content of blood and urine, and by P. B. Mack and J. Smith on the dietary habits and nutritional status of the members of 100 families with widely varying incomes.

[Food consumption studies by the South Carolina Station] (*South Carolina Sta. Rpt.* 1938, pp. 27–31, fig. 1).—This progress report (E. S. R., 79, p. 417) includes summaries of the completed studies by A. M. Moser on food consumption of farm families in the lower Coastal Plains region and by M. E. Frayser on the production and consumption of dairy products by farm households.

[Foods and nutrition research of the Texas Station] (*Texas Sta. Rpt.* 1937, pp. 27, 140–142).—Progress reports extending earlier work (E. S. R., 79, p. 129) are given by G. S. Fraps, R. Treicher, A. R. Kemmerer, and W. W. Meinke on the effect of different planes of carotene intake as the sole source of vitamin A on the health and longevity of rats; by J. Whitacre, L. R. Hawthorn, and S. H. Yarnell on factors affecting the storage of cucumbers; by Whitacre on the effect of tea upon the energy metabolism of children; by S. Cover on the effect of oven temperatures on the tenderness of meat; and by Cover, R. D. Turk, and H. Schmidt on the processing of canned meat.

[Studies in foods and nutrition by the Wisconsin Station] (*Wisconsin Sta. Bul.* 442 (1938), pp. 36–40, 77–80, 80–83, 92, 93, 96–98, 99–101, figs. 2).—Included in this progress report are summaries of studies, several of which represent extensions of earlier work (E. S. R., 78, p. 881) or have been noted previously. Among them are studies by H. Parsons, D. Johnson, and A. L. Marlatt in cooperation with G. M. Briggs and O. B. Combs on the effect of various processing temperatures on the nutritive value of the proteins of green edible and dry field soybeans (pp. 36, 37); by Parsons and E. Katz on the vitamin C content of several varieties of Wisconsin-grown apples (pp. 37, 38); by Parsons, E. Weagley, E. Slossmann, V. Helmke, and I. Baumann on the keeping quality and vitamin C content of home-made sauerkraut in sealed fruit jars (p. 38); by D. Husseman on the effect of season on the vitamin C content of tomatoes and of methods of preparation on the vitamin C content of home-canned tomato juice (pp. 38, 39); by Parsons, Johnson, L. Arent, and M. Sanders on the cause of egg white injury (pp. 39, 40); by H. A. Schneider and H. Steenbock on the production of kidney stones in rats kept on a low phosphorus diet (p. 77); by C. Krieger and Steenbock on the mechanism by which animals make use of phytic acid (pp. 77, 78); by A. C. Elvehjem and H. D. Anderson on the effect of the calcium-phosphorus intake on the utilization of iron (pp. 78, 79); by E. Van Donk and Steenbock on the need of vitamin A for satisfactory storage of iron (p. 79); by G. O. Kohler, Elvehjem, and E. B. Hart on attempts to treat nutritional anemia in rats with chlorophyll (p. 80); by E. J. and J. G. Lease, J. H. Weber, and Steenbock on factors affecting the utilization of vitamin A (pp. 92, 93); by W. Dasler and Steenbock on factors influencing the yield of vitamin D from ergosterol (pp. 96, 97); by J. J. Oleson, H. R. Bird, Elvehjem, and Hart on the factor in the vitamin B complex responsible for the prevention and cure of "spectacle eye" in rats

(pp. 97, 98); by Schneider, K. Ascham, and Steenbock on the distribution of vitamin B₁ in certain foods and Steenbock and F. Quackenbush on the identification of the active principle (p. 99); by D. V. Frost and Elvehjem on the possible complexity of factor W (pp. 99, 100); by M. A. Lipton, V. R. Potter, and Elvehjem on the role of vitamin B₁ in the synthesis of co-carboxylase and its significance in nutrition (p. 100); by F. E. Stirn, A. Arnold, and Elvehjem on the sparing action of fats for vitamin B₁ (pp. 100, 101); and by Elvehjem, O. Mickelsen, and H. A. Waisman on the effect of various methods of cooking on the vitamin B₁ content of meat products (p. 101).

The structure and composition of foods.—IV, Sugar, sirup, honey, tea, coffee, cocoa, spices, extracts, yeast, baking powder, A. L. and K. B. WINTON (*New York: John Wiley & Sons; London: Chapman & Hall, 1939, vol. 4, pp. XXXIII+580, figs. 13*).—In this volume, which continues the series noted previously (E. S. R., 78, p. 719), the general plan of the foregoing volumes has been followed in discussing the relation of structure to the composition of saccharine and alkaloidal products, spices and extracts, and leaven.

The effect of the method of heat application, and accompanying oven conditions, upon flavor and texture of baked foods, M. M. MONROE and P. S. GREENE (*Maine Sta. Bul. 391 (1938), pp. 277-279*).—This progress report summarizes data on oven temperatures required for heat absorption in glass and metal pans and the effect of oven air moisture on the consumption of electricity in thermostatically controlled ovens.

The preservation of fruits and vegetables in cold storage lockers, D. KNOWLES (*North Dakota Sta. Bimo. Bul., 1 (1939), No. 3, pp. 19-25*).—This is a summary of available information from various sources on the types and varieties of fruits and vegetables suitable for small-scale freezing for locker storage, their selection and preparation for freezing, the best temperature for freezing and storage, and methods for using the frozen products, including directions for cooking frozen vegetables. Convenient tables are included on the principal kinds of fruits and vegetables usually adaptable for freezing, the temperature and time for scalding certain vegetables, and the entire procedure for freezing different kinds of fruits and vegetables.

Food planning for four hundred millions, RADHAKAMAL MUKERJEE (*London: Macmillan & Co., 1938, pp. XVIII+267, figs. 6*).—The author surveys the trend of food supply in relation to population increase in India and compares the diets of the people in different regions and classes with various standards of nutrition. In addition to discussions on crop planning and nutrition and ways of adapting agricultural production to population pressure, the various social factors which contribute to increase of population are considered.

Diets of families of employed wage earners and clerical workers in cities, H. K. STIEBELING and E. F. PHIPARD (*U. S. Dept. Agr. Circ. 507 (1939), pp. II+141, figs. 9*).—The nutritive adequacy of the diets of 2,272 white and 222 Negro families in 43 industrial centers in 8 major geographical regions of the United States was calculated from dietary records obtained by the Cost of Living Division of the U. S. Bureau of Labor Statistics. In using the information on the kind, quantity, and money value of the food secured in 1 week during the period of December 1934 to February 1937, no deductions were made for waste of edible food. The white families had incomes ranging from \$3.48 to \$15.51 and the Negro families from \$2.96 to 9.08 a person a week.

The families were grouped in eight classes on the basis of food expenditures a person a week, ranging from less than \$0.63 to \$4.38 and over, the intervals used in the classification having been adjusted to the 1935 levels of retail food costs. The middle half of the 282 white families in the East South Central

cities spent from \$1.60 to \$2.75 a person a week for food as compared to from \$1.85 to \$3 by the median families of the 39 West South Central families, from \$2 to \$3 by those of the 76 Rocky Mountain region families, \$2 to \$3.10 by those of the 98 South Atlantic families, from \$2.10 to \$3.35 by those of the 381 East North Central families, from \$2.15 to \$3.50 by those of the 843 North Atlantic families, from \$2.20 to \$3.60 by those of the 112 West North Central families, and \$2.25 to \$3.60 a person a week by the middle half of the 441 Pacific region white families. The middle half of the 222 Negro families spent from \$1.05 to \$2.15 in the southern cities and from \$1.75 to \$3.65 a person a week in the Middle Atlantic cities.

When the diets were classified according to their nutritive content per requirement unit, as adopted by the Bureau of Home Economics, 11 percent of the white families in the North Atlantic cities were obtaining a good diet, 32 a fair, and 57 percent a poor diet, as compared to 12, 28, and 60 percent, respectively, for the East North Central families; 21, 33, and 46 percent, respectively, for the East South Central families, and 14, 46, and 40 percent, respectively, for the white families in the Pacific region. Eleven percent of the Negro families were obtaining a good diet, 25 a fair, and 64 percent a poor diet. The diets were in definite need of improvement with respect to one or more nutrients when the white families spent less than \$1.60 a person a week for food in the Pacific and North Atlantic cities, \$1.55 in the East North Central, and \$1 in the East South Central cities, and when the Negro families spent less than \$0.95 a person a week. The comparison did not include the more limited data on the diets of the families in the other four regions.

The white families spent from one-fourth to one-third of their food money for eggs, lean meat, poultry, and fish; from one-fifth to one-fourth for vegetables and fruits; and from one-eighth to one-sixth for milk and cheese. The Negro families spent about one-third for eggs, meat, poultry, and fish; one-sixth for fruits and vegetables, and only 6 percent for milk. The remainder was expended largely for grain products, fats, and sugars. As the expenditures for foods increased, there was a more liberal use of milk, meat, eggs, green vegetables, and fruits. Of every 10 white families spending enough to obtain a fully adequate diet, only from 2 to 4 were selecting good diets. Among the Negro families the proportion was a little over 3 out of 10.

Arsenic in the nutrition of the rat, E. HOVE, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 124 (1938), No. 1, pp. 205-212, fig. 1).—In continuation of previous studies (E. S. R., 62, p. 688), the authors report that the administration of 1 or 5 μ g. of arsenic per day to young rats receiving a milk diet with manganese and iron or iron and copper supplements did not affect growth, hemoglobin levels, or red blood cell count and fragility during a 6-week test period. Upon the withdrawal of the mineral supplements the anemic rats receiving arsenic showed a slight initial delay in the fall of the hemoglobin level. It is concluded that if arsenic is required by the rat during the growing period or for the building of hemoglobin or red blood cells the requirement is met by the approximately 2 μ g. of arsenic contained in the 50-cc. daily intake of milk.

Aluminum in the nutrition of the rat, E. HOVE, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 123 (1938), No. 3, pp. 640-643).—Three groups of rats on a whole milk diet supplemented with iron, copper, and manganese salts were given 0, 10, and 30 μ g. of aluminum as aluminum sulfate per day. Assuming a 50-cc. daily milk intake, each rat received from 1 to 1.5 μ g. of aluminum per day from the milk. Analyses of the blood and livers of the rats showed that the aluminum was absorbed from the intestinal

tract, removed fairly rapidly from the blood stream, and stored in the liver. Reproduction and the oestrous cycle were not affected. The aluminum exerted a very slight stimulating effect on the growth of some of the rats during the 6-week period following weaning. It is concluded that if the growing rat needs aluminum the 1 μ g. per day contained in the milk intake meets the requirement.

Iron deficiency in pregnant rats: Its effect on the young, H. L. ALR (*Amer. Jour. Diseases Children*, 56 (1938), No. 5, pp. 975-984).—Observations were made before and after one and two pregnancies on female rats maintained on a whole milk powder diet, with and without iron and copper supplements, and on the newborn offspring.

One to 4 days before the first delivery the hemoglobin values averaged 12.9 gm. per 100 cc. for the rats receiving no supplement, 11.9 gm. with 0.5 mg. copper, 11.6 with 5 mg. iron, and 13 gm. for the rats receiving both iron and copper supplements. At 21 days post partum the hemoglobin values of the four groups averaged 12.4, 12.6, 14.6, and 14.8 gm. per 100 cc., and the iron content of the liver was 5.8, 5.7, 25.2, and 28.2 mg. per 100 gm. respectively. The erythrocyte counts were from 6.4 to 7.4 million before delivery and from 7.8 to 8.5 million per cubic millimeter at 21 days post partum. Just before delivery in the second pregnancy the hemoglobin values averaged 9.9 gm. per 100 cc. for the rats receiving no supplement and 11.2 gm. for the group receiving the copper supplement, and at 21 days post partum the values had decreased to 9.1 and 8.4 gm. respectively. The liver iron content was 5 and 5.2 mg. per 100 gm., respectively. The erythrocyte count was 7.7 and 7.4 million per cubic millimeter for the two groups before delivery and 8.9 and 9.2 million, respectively at 21 days post partum.

The first litter offspring of female rats with mild iron deficiency had a normal hemoglobin content, but their liver stores of iron were depleted. A moderate deficiency of iron in the mothers resulted in anemia in the newborn, with hemoglobin values reduced about 25 percent from the normal value and the total iron content of the body reduced by more than 50 percent. The administration of copper supplement to the pregnant rats did not prevent the occurrence of anemia in the offspring, but the administration of iron and copper completely protected the young against iron deficiency. The erythrocyte counts for the newborn rats did not vary significantly. In the second litter offspring the iron deficiency was much more severe, with hemoglobin values of 6.6 gm. per 100 cc. and the total body iron content decreased to almost one-fourth normal at birth, with markedly decreased erythrocyte counts. The hemoglobin values of some of the offspring of both litters, which averaged 9.9 gm. at birth, increased slightly for a few days and then gradually decreased to about 6.4 gm. per 100 cc. at the end of 18 days, which does not represent pathologic anemia for rats of this age group.

The quantitative requirement of vitamins of different species as a function of their size [trans. title], P. MEUNIER and Y. RAOUL (*Compt. Rend. Soc. Biol. [Paris]*, 129 (1938), No. 34, pp. 1078-1080, fig. 1).—On the basis of estimated requirements of different species for the various vitamins, the authors have plotted logarithmic curves from the weights of the species as abscissas and the estimated vitamin requirements as ordinates. From the straight line curves thus produced it has been concluded that the daily dose of vitamin producing analogous effects in comparable animals can be determined from the formula $v=KM^r$, where r =quantity of vitamin, K a constant which is different for each vitamin, and M the weight of the animal in question.

Influence of avitaminoses on weights of endocrine glands, B. SUEZ (*Univ. Ark.*). (*Endocrinology*, 23 (1938), No. 5, pp. 575-580, fig. 1).—A brief

report, with tabulated data, is given of a comparison of the weights expressed as percentages of body weight of the pancreas, adrenals, thymus, thyroid, and pituitary of rats on diets deficient in various vitamins with the weights of corresponding glands of controls restricted to the same plane of nutrition. An increase in the endocrine weights of the pathological animals over corresponding weights of the controls is referred to as hypertrophy and a decrease as atrophy. The most significant observations were hypertrophy of the pancreas in vitamin A-deficient rats, of the thyroids and adrenals in vitamin B₁-deficient rats, and of the pituitary in B₁- and G-deficient rats. Atrophy of the thymus occurred in all the vitamin B₁-deficient rats studied.

Effect of vitamin A deficiency on the rate of apposition of dentin, I. SCHOUR, M. C. SMITH, and M. M. HOFFMAN. (Univ. Ill. and Univ. Ariz.). (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 3, pp. 447-450, fig. 1).—The daily rate of apposition of dentin was studied in 60 rats on a vitamin A-deficient diet by giving two intraperitoneal injections of 0.5 cc. of a 2-percent solution of alizarin Red S and measuring, in ground sections of incisors, the distance between the depositions of alizarine and dividing this by the time interval.

Within from 9 to 19 days the average daily rate of apposition was from 16.14 μ to 19.63 μ in the labial, from 11.14 μ to 14.38 μ in the distolingual, from 9.01 μ to 13.76 μ in the mesiolingual, and from 6.43 μ to 13.42 μ in the midlingual portions of the incisors. Within from 1 to 5 days after the administration of cod-liver oil to 7 of the rats the rate of apposition returned to the normal rate of about 16 μ . The authors suggest the possible use of the reaction as a biologic method of measuring the vitamin A content of foods.

Production of renal calculi in guinea pigs by feeding them a diet deficient in vitamin A, M. STEINER, B. ZUGER, and B. KRAMER (*Arch. Path.*, 27 (1939), No. 1, pp. 104-114, figs. 4).—In view of the uncertainty concerning the role of vitamin A deficiency in the formation of renal calculi as previously studied on rats, the authors used guinea pigs as experimental animals and obtained evidence of renal and urethral calculi in 9 out of 35 animals on a diet deficient in vitamin A alone and in none of 24 animals on diets adequate in vitamin A. The histological sequences in the pelvis and ureter from normal uroepithelium to stratified, keratinized epithelium are described, with illustrative microphotographs. The deficiency apparently caused hyperplasia at first, then metaplasia, and finally atrophy of pelvic and ureteral mucosa, large plaques of desquamated epithelium acting as the niduses for the development of calculi. Analyses of the calculi indicated that the inorganic fraction consisted entirely of calcium carbonate.

Vitamins and vitamin deficiencies.—I, Introduction and historical vitamin B₁ and beri-beri, L. J. HARRIS (London: J. & A. Churchill, 1938, vol. 1, pp. XIV+204, figs. 50).—This volume, which has a foreword by F. G. Hopkins, is the first of a series planned to provide a comprehensive synopsis of the results of modern research on each of the known vitamins. As the introductory volume to the series, it contains a brief historical section on the discovery of vitamins and their separation and naming. The three sections in which the material on vitamin B₁ is presented deal, respectively, with beriberi as a vitamin B₁ deficiency disease and the related types of polyneuritis, with prophylaxis and treatment; the concentration, isolation, physical and chemical properties, and synthesis of the vitamin, alternative methods for its estimation, its occurrence in foods, and its storage and metabolism in the body; and nutritive functions, with special emphasis on the relation of vitamin B₁ to carbohydrate metabolism. Literature references are given at the end of each chapter.

Vitamin C and chlorophyll [trans. title], A. MIRMANNOFF (*Compt. Rend. Acad. Sci. [Paris]*, 206 (1938), No. 10, pp. 766-768).—Using the Meunier electro-photometric method of determining ascorbic acid, the author has compared the content of the vitamin in corresponding green and white leaves and in various structural parts of plants, with the conclusion that richness in ascorbic acid in vegetable material is primarily a function of the anatomical structure of the plant and is not dependent upon chlorophyll per se, although it is thought probable that photosynthesis has some influence on the elaboration of the vitamin. In illustration, green and white leaves of lettuce gave values of 11.2 and 16 mg., brussels sprouts 67 and 69, and iris 178 and 201 mg., respectively, per 100 gm. of fresh plant. Beans germinated in the light had a content of 116 mg. in the green leaves and 121 mg. per 100 gm. in the green stems, and those germinated in the dark 84 and 18.5 mg. per 100 gm., respectively.

Losses of vitamin C during boiling and steaming of carrots, F. FENTON, D. K. TRESSLER, S. C. CAMP and C. G. KING. (Cornell Univ. and N. Y. State Expt. Sta. et al.). (*Food Res.*, 3 (1938), No. 4, pp. 403-408).—In continuation of previous studies (E. S. R., 80, p. 139), the authors determined the ascorbic acid content of carrots (Chantenay variety), using the Mack and Tressler modification (E. S. R., 78, p. 154) of the indophenol titration method. The fresh raw carrots contained from 0.044 to 0.060 mg. of ascorbic acid per gram. After boiling in water for 15 min. the sliced carrots had retained about 56 percent of the original content, the cooking water contained 33 percent, and 11 percent of the ascorbic acid content had been destroyed. A 20-min. steaming process removed only 14 percent of the ascorbic acid content from thinly sliced carrots.

Losses of vitamin C during commercial freezing, defrosting, and cooking of frosted peas, F. FENTON and D. K. TRESSLER. (Cornell Univ. and N. Y. State Expt. Sta.). (*Food Res.*, 3 (1938), No. 4, pp. 409-416).—In continuation of a series of studies (E. S. R., 80, p. 427) and following the Mack and Tressler modification (E. S. R., 78, p. 154) of the indophenol titration method, the authors determined the vitamin C content of raw and cooked frosted peas of the Thomas Laxton variety and compared the values with those obtained previously (E. S. R., 79, p. 138) for cooked fresh peas of the same variety.

The fresh raw peas contained 0.25 mg. of ascorbic acid per gram and the frozen peas 0.18 mg. per gram. A loss of about 38 percent occurred during blanching, chilling, and packaging of the peas. The cooked frosted peas taken directly from storage at -40° F. retained 50 percent of the ascorbic acid content, and 36 percent was dissolved in the cooking water. The cooked frosted peas after refrigeration for 16 hr. at 40° F. retained 56 percent, with 39 percent of the ascorbic acid content dissolved in the cooking water. The ascorbic acid content of the cooked frosted peas was 0.12 mg. as compared to 0.11 mg. per gram for cooked fresh peas of the same variety.

Studies in the use of crystalline vitamin C (ascorbic acid) in the prophylaxis and treatment of infantile scurvy and some other disorders of infancy and childhood, A. S. KENNEY and M. RAPOPORT (*Jour. Ped.*, 14 (1939), No. 2, pp. 161-162, figs. 16).—Miscellaneous observations on the use of crystalline vitamin C are reported as follows:

In doses of 1.53 mg. per kilogram of body weight daily for a period of 5 mo. crystalline ascorbic acid afforded complete protection from clinical or roentgenological evidence of scurvy in infants. The total quantity required to produce a degree of healing in scurvy resulting in freedom from pain and tenderness in the legs varied from 100 to 500 mg., with an average of 310 mg. With both ascorbic acid and orange juice, longer periods were required before healing could be noted in X-ray examination. A suggested treatment of

scorbutic infants with crystalline vitamin C is to give a daily dose of 500 mg. for 4 days to produce a condition of saturation and then a daily maintenance dose of from 25 to 50 mg. The administration of crystalline ascorbic acid caused no apparent temperature elevation in afebrile subjects.

In three of five anemic infants free from infection upon whom blood studies were made during ascorbic acid therapy, definite improvement in the blood picture occurred. In two others there was no response in the hemoglobin or red cells. The authors are inclined to think that when the iron reserves of the body are not so depleted that iron is no longer available for hemoglobin formation vitamin C has a favorable effect on hematopoiesis, and suggest that the failure of some anemic infants and children to respond to iron therapy may be due to inadequate vitamin C intake. In six scorbutic infants showing an increase in the size of the heart there was a marked degree of anemia. In one observed after cure of the scurvy no decrease in the heart size was evident. This is thought to suggest that factors other than vitamin C deficiency may be operative in producing the cardiac enlargement noted.

Capillary resistance tests by the positive pressure method gave positive results in all but 1 of 13 scorbutic infants, but following the administration of ascorbic acid negative tests resulted in only 2 cases. The opinion is expressed that, while petechiae can usually be produced in the scorbutic infant, "the administration of vitamin C in amounts sufficient to initiate clinical healing of scurvy will not always produce early disappearance of this phenomenon." A single case is given of an infant operated on for pyloric stenosis in whom the healing of the wound was apparently stimulated within 24 hr. by the intravenous administration of a single dose of ascorbic acid (300 mg.).

Complete case histories are given of three infants during therapeutic treatment with crystalline vitamin C.

The normal value [of ascorbic acid] for man [trans. title], A. GIBOUD, M. RABINOWICZ, and E. HARTMANN (*Bul. Soc. Chim. Biol.*, 20 (1938), No. 9-10, pp. 1097-1101, fig. 1).—The extremely low figures for the ascorbic acid content of human tissues in the limited amount of information available from autopsy material and the large quantities of ascorbic acid commonly required to saturate the tissues, as determined by urinary excretion after test doses, are considered to indicate that human diets as a rule are deficient in vitamin C and that this may account for low resistance to infection.

The normal amount of ascorbic acid [trans. title], A. GIBOUD, C. P. LEBLOND, R. RATSIMAMANGA, and E. GERO (*Bul. Soc. Chim. Biol.*, 20 (1938), No. 9-10, pp. 1079-1087, figs. 2).—Determinations, usually by the Tillmans titration method, of the content of ascorbic acid in certain organs and tissues of various species capable of synthesizing the vitamin have shown a remarkable constancy in the concentration of the vitamin in any specific organ or tissue. This more or less constant quantity in decreasing order of adrenals, liver, kidney, and muscle tissue is considered to be in proportion to the essential functions of the particular organ or tissue. In species which are capable of synthesizing vitamin C it is suggested that the normal state of vitamin C nutrition is that in which the quantity of ascorbic acid found in any particular organ will be similar to that in the same organ of animals which synthesize vitamin C.

Realization of the normal value [of ascorbic acid] in the guinea pig [trans. title], A. GIBOUD, C. P. LEBLOND, R. RATSIMAMANGA, and E. GERO (*Bul. Soc. Chim. Biol.*, 20 (1938), No. 9-10, pp. 1088-1096, figs. 4).—Guinea pigs fed various doses of pure ascorbic acid or vegetables furnishing known quantities of the vitamin were sacrificed for determinations of the ascorbic acid content of the adrenals, liver, and kidneys. It was found that not until the daily

intake of ascorbic acid reached 50 mg. did the content of ascorbic acid in the organs tested reach that characteristic for the particular organ in the species examined in the study noted above. On plotting as abscissas the logarithms of various doses of vitamin C furnished and as ordinates the mean values obtained for the ascorbic acid content of the adrenals, a straight line curve resulted. As a final test of the guinea pig requirements for vitamin C, two groups of 7 and 5 animals each were fed for 20 and 18 days, respectively, ad libitum on a mixed diet rich in fresh vegetables and were then sacrificed for determinations of the vitamin C content of the various organs. In both cases the values obtained corresponded closely to those obtained in the first study. It is concluded that the guinea pig requires about 50 mg. of ascorbic acid daily to maintain the normal concentration of vitamin C in its organs and tissues.

The vitamin C status of college women as determined by urinary excretion, H. S. MITCHELL, O. A. MERRIAM, and E. L. BATCHELDER. (Mass. State Col. and R. I. Expt. Sta.). (*Jour. Home Econ.*, 30 (1938), No. 9, pp. 645-650, figs. 2).—The subjects of this investigation were two groups of freshmen women students at Massachusetts State College and a group of freshmen and another of junior women students at Rhode Island State College. The two Massachusetts groups were tested soon after entering college and again in the following spring. For all subjects, totaling 210 freshmen and 40 juniors, ascorbic acid titrations by 2,6-dichlorophenolindophenol were made of 24-hr. samples of urine preserved with glacial acetic acid in glass jars protected from the light and kept in the refrigerator until tested, for the most part directly following the last collection.

On the students' ordinary diet, with no guidance as to food selection to secure an abundance of vitamin C, wide variations were shown in the first values obtained from the freshmen students, minimum, maximum, and average values for the three groups being, 3, 80, and 20 mg. per 24 hr., 8, 78, and 22, and 1, 73, and 15 mg. per 24 hr., respectively. Corresponding values obtained in the second period for the two Massachusetts groups and for the group of Rhode Island juniors were 7, 145, and 33 mg. per 24 hr., 3, 106, and 27, and 2, 158, and 28 mg. per 24 hr., respectively. The graphic array of individual data showed a striking similarity in the distribution of values in the various groups in the first period, there being a closer correspondence among the three groups than in the same groups when tested in the fall and spring. The higher values in group 2 are thought to reflect aroused interest in the selection of foods for their vitamin C content either through direct advice or increased knowledge of food selection.

Data are also reported on the urinary excretion of ascorbic acid by a few of the subjects after test doses of 300 or 400 mg. of crystalline ascorbic acid. In general the subjects with low preliminary excretion values and better food histories excreted a relatively larger proportion of the test dose than those whose preliminary excretion was low.

The behavior of ascorbic acid in pregnancy, at childbirth, during the puerperium, and in the first days of the life of the infant [trans. title], A. ELMBY and P. B. CHRISTENSEN (*Klin. Wochschr.*, 17 (1938), No. 41, pp. 1432-1434, fig. 1).—Data are reported on the ascorbic acid content of the blood of 200 women in the fifth and ninth months of pregnancy, at childbirth, and on the following fifth and tenth days, and of the cord blood, the breast milk at the fifth, tenth, and thirtieth days, and the ear blood of the newborn infants. The blood values were determined by the methylene blue method of Lund and Lieck or its micromodification by Elmby and With (*E. S. R.*, 77, p. 742) and the values for

milk by either the Tillmans or the methylene blue method, the former giving values from 10 to 20 percent higher than the latter. The subjects were divided into three classes relative to the abundance of citrus fruits, potatoes, other vegetables, milk, and meat in their diet. The women in the third or highest class consumed as many as six oranges or lemons daily.

Although the absolute values reported are much lower than customarily given, owing to the method used, they show the same relative changes as have been reported in other studies. The serum ascorbic acid content of the blood of pregnant women was proportional to the abundance of vitamin C-rich foods in the diet. By the fifth month of pregnancy the values were slightly lower than corresponding values for nonpregnant controls and by the ninth month and at childbirth considerably lower, with no appreciable increase on the fifth or tenth day after childbirth. Cord blood was without exception considerably higher in ascorbic acid content than the corresponding blood of the mother and blood taken from the infant's ear somewhat lower than cord blood but higher than maternal blood. The ascorbic acid content of the breast milk was proportional to the richness of the mother's diet in vitamin C and showed very little variation in samples taken on the fifth, tenth, and thirtieth days. The lowest value reported for breast milk was 0.9 mg. and the highest 6.7 mg. per 100 cc. Enrichment of vitamin C-deficient diets with 100 mg. daily of ascorbic acid during the first 10 days after childbirth resulted in a marked increase in the ascorbic acid content of the milk. In the group on the most deficient diets, 26 out of 74 infants were prematurely born, in the middle group 6 out of 58, and in the group on the richest diets 3 out of 40 infants were prematurely born.

Vitamin C content of the blood in newborn infants, A. W. FLEMING and H. N. SANFORD (*Jour. Ped.*, 13 (1938), No. 3, pp. 314-321, figs. 2).—This report includes data obtained by the Farmer and Abt micro- and macromethods.

In a control group of 51 miscellaneous dispensary patients from 6 to 60 yr. of age, minimum, maximum, and average values for ascorbic acid of the blood plasma were 0.4, 1.8, and 0.99 mg. per 100 cc., with 76 percent of the subjects giving values between 0.5 and 1.2 mg. per 100 cc. In 123 newborn infants the values ranged from 0.4 to 1.2 mg. and averaged 0.753 mg. per 100 cc., with 78 percent of the values lying between 0.5 and 0.9 mg. In the 105 mothers of these infants corresponding values of 0.5, 1.4, and 0.884 mg. per 100 cc. were obtained, with 72 percent of the values lying between 0.8 and 1.2 mg.

Other data presented showed that the concentration of ascorbic acid in the infant's blood is directly determined by its concentration in the mother's blood, but that this has no effect on the volume of breast milk, the infant's birth weight, or early gains or losses in weight. The birth weight of the infant is not related to the ascorbic acid content of its own blood, but a gain in weight of the infant receiving breast milk of good quality with respect to ascorbic acid is followed by a small gain in the vitamin C content of the infant's blood. The concentration of ascorbic acid in the post-partum blood of the mother was found to be proportional to her vitamin C intake during pregnancy, the values reported ranging from an average of 1.88 mg. for 9 women on a vitamin C intake equivalent to one orange a day to 0.546 mg. per 100 cc. for a group of 9 receiving less than one orange a week.

The content of reduced ascorbic acid in blood plasma in infants, especially at birth and in the first days of life, P. W. BRAESTRUP (*Jour. Nutr.*, 16 (1938), No. 4, pp. 363-373, fig. 1).—The blood plasma of 22 women immediately after childbirth contained from 0.12 to 0.72, with an average of 0.26, mg. ascorbic acid per 100 cc. as determined by the Farmer-Abt micromethod. Corresponding values for cord blood were 0.36, 2.6, and 1.07 mg. per 100 cc.

and for the heel blood of the infants at birth 0.28, 1.28, and 0.69 mg. per 100 cc. and on the tenth day of life 0.12, 0.64, and 0.27 mg. per 100 cc., respectively. Relatively high values in the mother were accompanied by proportionately high values in her infant.

In 5 infants from 2 to 5 weeks of age fed boiled cow's milk, plasma ascorbic acid determinations were made before and at intervals of a few days up to 28 days after the administration of ascorbic acid in amounts of 20 (3 subjects) and 10 mg. (2 subjects) per day, respectively. The values before the administration of ascorbic acid were very low, ranging from 0.12 to 0.34 mg. per 100 cc. and were increased only slightly following the ingestion of 10 mg. ascorbic acid daily for 15 days, but showed a marked increase following the ingestion of 20 mg. ascorbic acid or 1 oz. of orange juice daily. This difference is considered of significance in view of the fact that 20 mg. daily represents the minimum amount of ascorbic acid an infant receives when fed exclusively on human milk.

"An average daily intake of 150 cc. milk per kilogram body weight allows a minimum of 3 mg. and in most cases a customary intake of 5 to 8 mg. per kilogram of ascorbic acid daily for the first few months. Until reliable methods for the determination of vitamin C subnutrition are available this must be considered to be the standard intake. In practice this means that all infants who are not given human milk must have an extra supply of vitamin C corresponding in the first few months to at least 20 mg. of ascorbic acid daily. As the vitamin C content of human milk varies so greatly with the diet, it is preferable to give extra vitamin C in winter and spring, even to infants fed on human milk."

The determination of reduced and total ascorbic acid in blood plasma [trans. title], F. WIDENBAUER and E. SCHNEIDER (*Klin. Wchnschr.*, 17 (1938), No. 48, pp. 1694, 1695).—The authors have adopted the metaphosphoric acid precipitation of the protein in blood plasma according to the method of Farmer and Abt in connection with the methylene blue technic of Lund and Lieck (*E. S. R.*, 79, p. 151), and describe the technic for the determination of total and reduced ascorbic acid in blood plasma.

On the basis of a comparison of the reduced ascorbic acid content of the blood plasma of adults, children, and infants with data obtained by saturation tests, the following standards are suggested for judging vitamin C status from blood values: 1 mg. or over per 100 cc., very good; about 0.5 mg., good or average; from 0.35 to 0.25 mg., extremely poor; and 0.2 mg. per 100 cc. or below very deficient. The highest value obtained, 4.5 mg. per 100 cc., was from a woman who had been taking a pure vitamin C preparation for several months and the lowest, 0, in very ill, artificially fed, or prescorbutic infants.

An effect of lipid feeding upon vitamin C excretion by the rat, R. R. MUSULIN, R. H. TULLY, III, H. E. LONGENECKER, and C. G. KING (*Science*, 88 (1938), No. 2293, p. 552).—In attempts to discover the biological precursor of vitamin C, the authors have devised a technic for collecting 24-hr. samples of urine from rats without the loss of any ascorbic acid which may be contained therein, and have demonstrated that rats fed on a stock diet of Purina chow or Sherman diet No. 13 show a sharp drop in ascorbic acid excretion when deprived of food, or a more gradual drop when placed on a diet of condensed milk. Consequently the test animals are deprived of food for 3 or 4 days and are then given condensed milk alone for from 3 to 6 days, after which the substance to be tested as a precursor of vitamin C is fed as a supplement to condensed milk.

Common purified foodstuffs such as sugars, proteins, and oils have been found not to affect the rate of excretion of vitamin C, but the feeding of oats, oat oil, the unsaponifiable matter from oat oil, and halibut-liver oil, is followed promptly by a high rate of excretion of vitamin C, the response with respect to time and extent being comparable to that obtained by feeding the pure vitamin. Certain volatile fractions from liver oil and oat oil are particularly active, but the fatty acids and common sterols are inactive. The results have been verified by biological assays with guinea pigs. The possibility is recognized that the lipid effect may be exerted through an indirect agency, but the weight of evidence at the present time is thought to favor the interpretation that the vitamin is formed by conversion from lipid to carbohydrate.

The incidence of hemolytic streptococci in the tonsils of children as related to the vitamin C content of tonsils and blood, A. D. KAISER and B. SLAVIN (*Jour. Ped.*, 13 (1938), No. 3, pp. 322-333, figs. 5).—A group of 123 children from 6 to 16 yr. of age, selected by school physicians for various reasons to have their tonsils and adenoids removed, served as subjects for this comparative study of the vitamin C content of the blood and the vitamin C content and presence of hemolytic streptococci in the tonsils immediately after removal.

The vitamin C content of the blood ranged from 0.5 to 1.08 mg. and of the tonsils from 18.6 to 33.7 mg. per 100 cc. The presence of hemolytic streptococci in the tonsils was demonstrated in about 50 percent of the children, and an inadequate vitamin C intake, as far as could be ascertained by incomplete records obtained from the mother on the customary intake of citrus fruits, tomato juice, and pineapple juice, in about 40 percent of the children. Approximately one-third of the children had low values of vitamin C in both blood and tonsils, but comparisons of the values for the same children showed no constant relation. In children whose tonsils contained hemolytic streptococci the vitamin C content of both blood and tonsils was significantly lower than children whose tonsils did not contain hemolytic streptococci. In tests on mice it was demonstrated that 40 percent of the streptococci found in the tonsils of the children with the lowest vitamin C values were virulent, as compared with 30 percent when the vitamin C values were average and only 10 percent when they were above average.

The evidence is thought to suggest that an adequate concentration of vitamin C in the blood influences the incidence of hemolytic streptococci in the tonsils, although it is also possible that it is the infection in the tonsils that causes a lowering of the vitamin C content. As the concentration of vitamin C in the blood is probably determined by the dietary intake and the metabolism of vitamin C varies with the individual, it is concluded that from the clinical point of view it is desirable to supply children with more than the minimum amount of vitamin C in their diets.

The vitamin C status of diabetic patients, V. SIRESTA, R. M. SMITH, A. T. FERNALD, and A. MARBLE (*New England Jour. Med.* 220 (1939), No. 2, pp. 56-60).—The diabetic subjects studied, who were under observation at the clinic directed by E. P. Joslin, included 31 men and 46 women from 15 to 76 but chiefly over 50 yr. of age who were suffering from lesions of the extremities or convalescing from operations for them, but had no fever or obvious signs of infection. The diets of the patients prior to admission to the hospital were considered to be reasonably adequate in vitamin C, and the hospital diet was estimated to furnish from 80 to 140 mg. of the vitamin daily. Tabulated data reported for 49 of the subjects include the pertinent history, blood sugar, and ascorbic acid content of the fasting blood and ascorbic acid content of the

urine collected for 5 hr. following the intravenous injection of a 1,000-mg. dose of ascorbic acid.

In comparison with the standard suggested by Wright et al. (E. S. R., 79, p. 714) of an excretion of 400 mg. or more of the 1,000-mg. dose of ascorbic acid in the first 5 hr. and 0.8 mg. per 100 cc. as the lower limit for the ascorbic acid content of the fasting blood, only 6 of the 49 subjects showed definitely low values in both blood and urine and of these 4 were surgical cases. The fasting blood values usually bore a direct relation to the urine values, the exceptions being either borderline cases for blood or urine or surgical cases. Excluding the cases in which any surgical lesion might have been a complicating factor, only 9 patients gave any indication of a lowered vitamin C status. Of these, 2 had low values for both blood and urine, 3 low urine but normal blood, and 4 low blood but normal urine values. In 6 normal subjects used as controls the vitamin C content of the fasting blood ranged from 1.22 to 1.79 mg. per 100 cc. and the content in the 5-hr. urine from 495 to 886 mg.

The data are thought to indicate clearly that the average patient with uncomplicated diabetes is capable of a normal status as regards vitamin C if given adequate amounts of the vitamin in the diet. "With the increasing and laudable tendency to make diabetic diets more nearly like normal ones, this conclusion emphasizes anew the value of fruit, especially citrus fruit, and green vegetables, as included in the classic dietaries for patients with diabetes." The low values for blood and urine in surgical cases, including those who had been operated on and those who had unoperated lesions of the extremities, were considered by the authors as surprising in view of the fact that the patients had no definite signs of infection or that some time had elapsed since the operation. It would seem to indicate that both the infection and ensuing operation had caused an excess drain on the vitamin C reserves.

Vitamin C in tuberculosis.—The effect of supplementary synthetic vitamin C on the urinary output of this vitamin by tuberculous children, T. S. BUMBALO and W. W. JETTER (*Jour. Ped.*, 13 (1938), No. 3, pp. 334-340, figs. 2).—Following a period to determine the basic vitamin C elimination level, 50 mg. of synthetic ascorbic acid in tablet form was administered daily to 10 tuberculous children until normal excretory levels were established and maintained. One of the subjects was also observed daily after discontinuance of the vitamin and the others tested 2 weeks after discontinuance. As controls 6 normal healthy children with an average vitamin C intake comparable to the tuberculous group were studied for their normal excretion of vitamin C and were then given the same ascorbic acid supplement until the maximum increase in excretion was obtained, after which the supplement was discontinued and the urine again examined. Of the 10 tuberculous children all had pulmonary involvement, 8 were bed patients, and the nutrition was considered poor in 2 cases and fair in 8.

In the tuberculous group the average 24-hr. urinary excretion of ascorbic acid was 6.4 mg. over a period of 4 days. It required a total of 750 mg. of ascorbic acid over a period of 15 days to raise the daily excretion to slightly over 10 mg. and a total of 1,050 mg. in 21 days to raise it to 15 mg. The maximum daily excretion was 23 mg., reached in 24 days after a total intake of 1,200 mg. of ascorbic acid. After discontinuance of the vitamin supplement the values fell to the original low levels by the sixth day. Of the 10 subjects, in only the one who showed clinically the least involvement of any was there any considerable variation from the average, a total of only 600 mg. over a period of 12 days being sufficient to increase the excretion of ascorbic acid to 24 mg. In the healthy controls the average daily excretion of ascorbic acid during a

5-day preliminary period was from 30 to 35 mg., and on supplementary feedings of synthetic ascorbic acid the excretion rose sharply to an average of 70 mg. on the second day after a total intake of 100 mg. A maximum value of 77.5 mg. was noted on the fourth day. On discontinuance of the supplementary vitamin the excretion fell rapidly, reaching the previous level of from 30 to 35 mg. on the third day.

These results are thought to indicate a definite hypovitaminosis C in active tuberculosis and to suggest increased vitamin C intake as a therapeutic measure.

Vitamin C and resistance of the guinea pig to infection with *Bacterium necrophorum*, N. B. McCULLOUGH (*Jour. Infect. Diseases*, 63 (1938), No. 1, pp. 34-53, figs. 9).—The extensive and somewhat controversial literature on the relation of vitamin C deficiency to various pathological conditions and infections in experimental animals and human subjects is reviewed, with numerous footnote references, and studies are reported on the relation of vitamin C deficiency in guinea pigs to infection with human and animal strains of *B. necrophorum*.

Avirulent human strains did not produce infection in the animals receiving adequate vitamin C or in those with subacute scurvy, but produced minor abscesses in the extremely scorbutic animals. Vitamin C therapy resulted in prompt recovery of the infected animals. With the slightly more virulent animal strains infections were produced in both controls and vitamin C-deficient animals, but were much more severe in the latter and the animals died sooner than the controls.

The results are thought to afford good proof that vitamin C deficiency decreases resistance to infection, although a rather severe scorbutic condition is necessary before the weakened resistance is evident.

Infantile scurvy, G. L. CARR (*Med. Woman's Jour.*, 46 (1939), No. 3, pp. 75-81, figs. 6).—The discovery by roentgen examination of six cases of florid infantile scurvy and two cases of the subclinical type in a 250-bed hospital for indigent and near-indigent patients within a period of 3½ yr. is considered of significance in "these days of scientific feeding." One reason for the increase of incidence of the disease is thought to be the inability of the present medical student or intern to recognize the symptoms of a disease which has been so seldom seen in recent years.

Methods of determining vitamin C deficiency by capillary resistance tests and analyses of urine and blood plasma are reviewed briefly and the roentgen ray examination of the bones in considerable detail, particularly the rather difficult diagnosis in the earlier stages of scurvy and in the presence of incompletely developed rickets. Two case reports are given. One is for a 9-month-old infant who had gradually become depleted of vitamin C through inadequate supplements, but was cured by intramuscular injections of ascorbic acid, followed by massive oral doses of ascorbic acid and orange juice. The other case illustrates the development of scurvy in a premature infant while a hospital patient, with failure to identify the condition until examination on autopsy.

Vitamin D in diet: Palatable methods of supply, J. LANDSAY and V. H. MOTTRAM (*Brit. Med. Jour.*, No. 4070 (1939), pp. 14, 15).—On the principle that the fishy flavor of cod-liver oil will not be detected in fish dishes, recipes are given in which cod-liver oil is an ingredient. These include a white sauce to serve with boiled, steamed, or baked fish, 1 tablespoonful of which sauce will furnish from 40 to 200 International Units of vitamin D, according to the potency of the oil; a mayonnaise, 1 tablespoonful of which will contain from 1,700 to 8,500 I. U.; a fish soup furnishing from 375 to 1,500 I. U. per half pint; and a cod-liver oil-containing batter for the deep frying of fish or fish roe.

Degeneration of cross striated musculature in vitamin E-low rats, H. M. EVANS, G. A. EMBERSON, and I. R. TELFORD. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 38 (1938), No. 5, pp. 625-627, figs. 2).—The authors report that six rats reared and maintained on the vitamin E-low diet 427 developed a disability in locomotion accompanied by atrophy of the musculature of the flank and posterior limbs. Histological examination revealed degeneration of the muscle fibers.

Endemic fluorosis and its relation to dental caries, H. T. DEAN (*Pub. Health Rpts. [U. S.]*, 53 (1938), No. 33, pp. 1443-1452, pl. 1).—Dental examinations of 122 children residing in areas where the domestic water supplies contain from 1.7 to 3.5 p. p. m. of fluorine showed that 22 percent were free from dental caries as compared to 4 percent of a group of 114 children who had continuously used domestic water containing from 0.6 to 1.5 p. p. m. of fluorine. Analysis of data on the number of dental caries of over 8,000 children living in mottled enamel areas in a number of States revealed that the dental caries attack rate is inversely proportional to the presence of mottled enamel.

The antirachitic effect of some foods, E. F. KOHMAN, W. H. EDDY, M. E. WHITE, and N. H. SANBORN (*Food Res.*, 3 (1938), No. 4, pp. 373-381).—In this study, which was noted previously from a preliminary report (*E. S. R.*, 72, p. 588), the results of additional experiments are presented to show that the substitution in the Steenbock and Black diet 2965 of 50 percent of several mixtures of canned foods such as chicken, roast beef, asparagus, peas, and spinach produced maximum calcification of the femurs in rats. The addition of cod-liver oil did not alter the calcifying action when the diets contained 50-percent substitutions of natural foods, but in the presence of 25- or 30-percent substitutions the calcification was increased slightly by the oil.

Failure of nicotinic and yeast nucleic acids in "filtrate factor" deficiency in rats, G. A. EMBERSON and H. M. EVANS. (Univ. Calif.) (*Soc. Expt. Biol. and Med. Proc.*, 38 (1938), No. 2, pp. 195-197).—Twenty-four female rats were maintained on the Halliday and Evans diet S05 (*E. S. R.*, 78, p. 284), supplemented by 10 µg. of thiamin chloride 6 times a week. After 4 weeks the rats were given in addition 40 µg. of riboflavin and molasses eluate equivalent to 4 gm. of molasses and other supplements as follows: Group 1, no supplement; group 2, 5 mg. of nicotinic acid; group 3, 5 mg. of yeast nucleic acid; and group 4, 5 mg. of yeast nucleic acid plus 5 mg. of nicotinic acid.

All the animals showed similar growth responses during the first 15 days, and the addition of 5 gm. of liver in the form of liver filtrate adsorbed on fuller's earth to remove the vitamin B₁, riboflavin, and vitamin B₆ to 3 of the negative control rats in group 1 resulted in an average daily gain of 2 gm. for the remainder of the 56-day period as compared to 0.48 gm. for the negative controls in group 1, 0.46 for group 2, 0.45 for group 3, and 0.36 gm. for group 4. All rats except those receiving the liver filtrate developed a type of skin lesion dissimilar to the florid acroderma type of dermatitis characteristic of vitamin B₆ deficiency and had dull and lusterless fur.

TEXTILES AND CLOTHING

Co-operative project in textiles conducted by [six] northeastern experiment stations, A. B. SEARLE, E. N. CHAPMAN, and E. D. ROSEBERRY. (Pa. State Col.). (*Jour. Home Econ.*, 31 (1939), No. 3, pp. 177-184).—This is a preliminary report on the performance during wear of women's and children's wearing apparel fabrics, employing chemical, microscopic, and durability tests. The purposes of the study are to find the type of information of most value to

the retail purchaser of textile fabrics, to set tolerances for the grading of fabrics from the consumer point of view, and to provide a basis for planning units of work on the purchasing of fabrics for classes in textiles.

Of the 570 fabrics that have been analyzed since the study was begun in 1936, 227 were cotton, 188 rayon, 66 silk, 48 wool, 17 mixtures of wool and rayon, 6 of cotton and rayon, and 4 of wool and cotton, and 14 were miscellaneous fabrics. The data indicate that the present test for yarn and seam slippage is not rigorous enough to predict accurately wearing performance, and that the test for launderability of colored cotton fabrics does not give a satisfactory index to the colorfastness for more than one or two launderings.

Durability of wearing apparel fabrics, P. B. MACK and A. B. SEARLE. (Coop. 6 expt. stats.). (*Pennsylvania Sta. Bul.* 367 (1938), p. 46).—A progress report is given on the cooperative project noted above.

[Studies in textiles and clothing by the Iowa Station] (*Iowa Sta. Rpt.* 1938, pt. 1, p. 163).—Progress reports (E. S. R., 79, p. 572) are given on studies by R. Edgar of the protection from degradation which certain finishes provide wool and the comparative degradation of cotton cellulose and regenerated cellulose rayon by five oxidizing bleaches.

The usage of household textiles by farm families, M. E. FRAYSER (*South Carolina Sta. Rpt.* 1938, p. 32).—This progress report of a survey of quantities, kinds, and cost of textile materials used for household purposes by white and Negro farm families in the State contains tabulated data on sheets, pillows, and pillowcases.

Physical characteristics in cotton and their interrelationship, M. A. GRIMES (*Texas Sta. Rpt.* 1937, pp. 143, 144).—In this progress report (E. S. R., 79, p. 717) on the study of two varieties of cotton, the polarizing microscope method is being used for maturity tests and the Chandler method for strength tests. The fineness of the fibers is being determined from cross sections made with the Hardy device, the area of the projected section being measured with a planimeter.

"Nylon" and its identification, W. VON BERGEN (*Rayon Textile Mo.*, 20 (1939), No. 1, pp. 53-57, figs. 3).—The author describes the basic principle of the process for the production of the new fiber known as Nylon, which is an entirely synthetic material from fiber-forming polymeric amides having a protein-like chemical structure and derivable from coal, air, and water, or other substances. From various physical and chemical tests the chief advantages of Nylon are reported to be high breaking strength, an elongation of 22-26 percent in both the dry and wet states, high elastic properties, and lack of sensitivity toward water and various chemical agents. The individual filaments can be produced far finer than any other artificial fiber except glass fibers. The fiber has a good affinity toward silk and wool dyestuffs and some of the direct dyes used for cotton and rayon.

For quick identification of pure Nylon fibers, the burning test in an open flame is recommended as the simplest and most reliable. Instead of burning, Nylon fibers melt and fuse to a glassy globule, changing from light brown and transparent to black and tarlike, depending upon the length of the test. The odor given off during burning is similar to that of boiling string beans and entirely different from that of any other animal or vegetable fiber.

HOME MANAGEMENT AND EQUIPMENT

Home management with special reference to the college home management house, I. H. GROSS and M. E. LEWIS (*New York: F. S. Crofts & Co.*,

1938, pp. XI+162, figs. [7]).—Both the technological and the human values are emphasized in this textbook dealing with the problems related to the management of time, energy, money, and material resources. One chapter is devoted to the elements that enter into successful guidance of the work of others. The problems of human relations in a resident course in home management are discussed in a chapter on human values. A rating sheet for students in home management houses, suggestions for menu planning, and aids in meal planning are contained in an appendix.

[Home management studies by the Wisconsin Station] (*Wisconsin Sta. Bul.* 442 (1938), pp. 35, 36).—This progress report (E. S. R., 78, p. 598) consists of summaries of studies by M. L. Cowles and H. G. Ahlgren on the habits and preferences of Madison homemakers in the purchase and consumption of canned peas and by Cowles and G. Voigt on the comparative cost of house construction and purchase of women's and children's clothing.

Farm family living on a group of North Dakota farms, D. G. HAY and S. BEST (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 3, pp. 13-16, fig. 1).—This report covers the analysis of farm family account books kept for nearly a year in 1937 by 81 families in 24 counties of the State through the cooperation of the U. S. D. A. Farm Security Administration, of which the families were loan clients. The farms, which averaged 305 acres in size, were fully owned by 11 of the farm operators, partly owned by 16, and rented by 54. The average size of the family was 5.4 persons.

For the 75 families reporting total cash receipts, the lowest, highest, and average cash incomes from all sources were \$319, \$2,010, and \$990. The chief sources of these incomes, with the average for each source, were sale of crops \$161, poultry and dairy products \$161, and livestock \$126. Of the total average cash receipts, \$457 came from the farm and \$533 from Farm Security loans, supplementary grants, and other income.

From the records of 51 families who kept accounts of the farm products used by the family, the average cash value of family living furnished by the farm was calculated to be \$276. The average values of the farm products produced and consumed at home were \$72 and \$58 per adult male equivalent, using the Zimmerman standard (E. S. R., 62, p. 389), for the owner and tenant families, respectively. The difference in these values, which was chiefly in dairy products and meats, is thought to be due largely to the comparative insecurity of tenure of farm renters.

For the entire number of farm families the average cash expenditure for family living was \$369 per family, the owners averaging \$84 and the tenants \$92 per adult male equivalent. The proportional distribution of expenditures among the different items of family living was food 41 percent, clothing 15, household operation 9, housing and furnishing 5, medical care 5, education and recreation 4, gifts, church, and welfare 3, personal 2, payments on notes 5, and unclassified 11 percent.

MISCELLANEOUS

Statistical technique in agricultural research: A simple exposition of practice and procedure in biometry, D. D. PATERSON (*New York and London: McGraw-Hill Book Co.*, 1939, pp. [X]+263, figs. [18]).—A presentation of the plans of statistical analysis, with special reference to agricultural experimentation.

A handbook of statistics for use in plant breeding and agricultural problems, F. J. F. SHAW (*Delhi: Imp. Council Agr. Res., India*, 1936, pp. [5]+182, figs. 20).—A presentation of the elements of statistics of special application to the analysis of genetic and agricultural problems.

Forty-eighth Annual Report [of Alabama Station], 1937, M. J. FUNCHESS ET AL. (*Alabama Sta. Rpt. 1937, pp. 34, figs. 2*).—The experimental work reported is for the most part referred to elsewhere in this issue.

Sixty-first Report of the Connecticut Agricultural Experiment Station, New Haven, for the year 1937, W. L. SLATE ET AL. (*Connecticut [New Haven] Sta. Rpt. 1937, pp. [906], figs. 134*).—In addition to the usual administrative data, this report contains reprints of Bulletins 404-416, all of which have been noted previously, and the following circulars: Nos. 119, A New, Early, Productive Summer Squash, by L. C. Curtis (pp. 1-7); 120, Requirements for Tree Workers in Connecticut (pp. 9-24); 121, Vegetable Pest Control Schedule, by N. Turner and A. A. Dunlap (pp. 25-49); 122, The "X Disease" of Peach, by E. M. Stoddard (pp. 53-60); 123, The Use of Water Soluble Preservatives in Preventing Decay in Fence Posts and Similar Materials, by H. W. Hicock (pp. 61-68); 124, Law and Regulations Concerning the Inspection and Shipment of Nursery Stock in Connecticut, by W. E. Britton (pp. 69-75); and 125, Regulations Concerning Transportation of Nursery Stock in the United States and Canada, compiled by W. E. Britton (pp. 77-105).

Report on agricultural research [of Iowa Station] for the year ending June 30, 1938, I, II, R. E. BUCHANAN ET AL. (*Iowa Sta. Rpt. 1938, pts. 1, pp. 262, figs. 17; 2, pp. 80, figs. 4*).—Part 1 of this report includes reports on all active projects except those relating to work coordinated under the Iowa Corn Research Institute, which is included in part 2. The experimental work not previously noted is for the most part referred to elsewhere in this issue.

Report of progress [of Maine Station] for year ending June 30, 1938, [F. GRIFFEE ET AL.] (*Maine Sta. Bul. 391 (1938), pp. 233-332, figs. 6*).—This contains data noted for the most part elsewhere in this issue or previously.

Fifty-first Annual Report [of Cornell Station], 1938, C. E. LADD ET AL. (*[New York] Cornell Sta. Rpt. 1938, pp. 72-169*).—The experimental work reported is for the most part noted elsewhere in this issue.

Science serving agriculture: [Biennial Report of Oklahoma Station, 1937-38], L. S. ELLIS (*Oklahoma Sta. [Bien.] Rpt. 1937-38, pp. XV+231, figs. 41*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Special agricultural investigations, compiled by B. S. BESSE and J. C. BUETNER (*Oregon Sta. Circ. 130 (1938), pp. [2]+50, figs. 121*).—A preliminary report of research authorized by the Oregon Legislature, 1937 Session, the findings for the most part being abstracted elsewhere in this issue.

Fifty-first Annual Report of the Pennsylvania Agricultural Experiment Station, [1938], R. L. WATTS ET AL. (*Pennsylvania Sta. Bul. 367 (1938), pp. [4]+68, figs. 14*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fifty-first Annual Report of the South Carolina Experiment Station, [1938], H. P. COOPER ET AL. (*South Carolina Sta. Rpt. 1938, pp. 199, figs. 40*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fiftieth Annual Report [of Texas Station], 1937, A. B. CONNER ET AL. (*Texas Sta. Rpt. 1937, pp. 321*).—The experimental work not previously reported is for the most part noted elsewhere in this issue.

What's new in farm science: Annual report of the director, [Wisconsin Station, 1938], I, compiled by N. CLARK and N. HOVELAND (*Wisconsin Sta. Bul. 442 (1938), pp. 113, figs. 20*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

NOTES

Arkansas University and Station.—The College of Agriculture has been given 100 acres of delta land near Clarkedale. This tract will be operated as a substation of the Cotton Branch Station and will be devoted to the breeding of cotton and corn and experimental work with insect control, legumes, and small grains on the delta soil. The construction of the necessary buildings is under way.

The retirement from public service is announced of Dean and Director Dan T. Gray, who is resigning as of July 1. As a recent statement announces, "under Dean Gray's administration and guidance the work of the College of Agriculture has grown in its effectiveness and service to the State. When he became dean and director in 1924, only two-thirds of the counties had the services of county agents and slightly over half had the leadership of home demonstration agents. Today all counties have county agents and home demonstration agents, and in addition 24 assistant agents are employed in the larger counties. Through his efforts a branch experiment station system was established in 1926 for the purpose of extending the college's research program in order that work might be done in areas of production in the State. There are now four branch experiment stations—the Cotton Branch Station in Lee County, Rice Branch Station in Arkansas County, Fruit and Truck Branch Station in Hempstead County, and the Livestock and Forestry Branch Station in Independence County—involving 3,700 acres of land devoted to agricultural investigations in the interest of the State's farm people. As the result of his progressiveness, student enrollment in the college has nearly trebled, and the College of Agriculture now ranks second among the colleges of the university in the number of students enrolled. . . .

"Among other contributions he has made to Arkansas agriculture are the development of an outstanding staff of workers; formation of a land-use program for the State; development of an educational program for older rural boys and girls; establishment of a program for outlying experimental work conducted in cooperation with farmers on their farms; development of a live-at-home program; establishment of study days and visiting days for 4-H Club members, vocational agriculture students, and adult farm people at the main and branch experiment stations; and the development of a broad research program with enlarged physical facilities such as buildings, land, and equipment."

Jack D. Paul, technical assistant, and H. W. Bitting, cooperative research supervisor, at the Rice Branch Station have resigned. The former has been succeeded by Travis C. Keahey.

California University and Station.—Three new buildings have been provided for the Davis campus. One of these is a new laboratory building for enology, which has been completed at a cost of slightly over \$100,000. The building is composed of three main divisions, more or less self-contained. The utility section, which is 86 by 45 ft., with a basement, houses three air-conditioned fermentation and finishing rooms, refrigerated cellars or aging rooms, two cold-storage rooms, two high temperature rooms for aging and conditioning certain types of wines and brandies, distillation apparatus, an office, and a yeast laboratory. The

office and research wing, 34 by 50 ft., houses two laboratories, a wine library, and three offices. The instruction unit is 30 by 31 ft., with a basement, and includes a student laboratory equipped for sections of 18 students, an air-conditioned fermentation room, and two refrigerated aging rooms.

As an aid in commercial as well as experimental plant cultures under glass, an air-conditioned greenhouse unit has been completed as a cooperative project between the divisions of agricultural engineering and truck crops at Davis, the department of electrical engineering at Berkeley, and the California Committee on the Relation of Electricity to Agriculture. The latter committee has made a grant of \$2,500 during a 2-year period to further the project. Half of a 100-by 30-ft. house has been rebuilt and equipped, the other half operating as a check. Installation of equipment and controls has been completed, and plantings are being made. Although under normal interior valley conditions greenhouses can be used but 5 months of the year, this house is designed for all-year use and will permit a varied range in humidities and temperatures. Plans for studies on variation in light quality and intensity are also contemplated as a part of a comprehensive study of environmental factors affecting plant growth.

A new library and administration building is expected to be ready for use by the opening of the second semester in January 1940. This is a two-story building, 300 ft. long. One wing will house administration offices, and the first floor of the middle section will provide classroom and office space, a map and herdbook room, a browsing room for student use, and library staff and work rooms. The main reading room, 144 by 48 ft., will occupy the entire middle section of the second floor. Provision for 90,000 volumes is being made. The building is a joint P. W. A.-university project, costing \$325,000.

Dr. E. C. Van Dyke, professor of entomology, retired July 1 after 26 years of service to become professor of entomology emeritus. His work in entomological history and taxonomy will be carried on by E. O. Essig, whose duties in agricultural entomology will be undertaken by Dr. Guy F. MacLeod, professor of economic entomology at Cornell University. Drs. E. Gordon Linsley and Robert L. Usinger have been added to the staff as instructors in entomology, the former to be stationed at Berkeley and the latter at Davis.

Connecticut State Station.—Dr. Roger B. Friend, associate entomologist, has been appointed State entomologist and head of the department of entomology. Dr. Donald F. Jones, chief geneticist, has been elected a member of the National Academy of Sciences.

Purdue University.—Dr. Eldyn Everett Van Lone, assistant professor of animal husbandry since 1932, died April 5 at the age of 44 years. A native of Wisconsin, he received from the University of Wisconsin the B. S. degree in 1923, the M. S. degree in 1924, and the Ph. D. degree in 1931. While primarily a teacher of genetics, he had found time to conduct a considerable amount of experimental work on inheritance of hair pattern and color, characters that control sterility, and the colors of fat. He was an active collaborator on a project to study the physical, chemical, and histological changes of meat during quick freezing and storage at low temperatures. His genetics library, consisting of 93 bound volumes and a collection of periodicals, has been donated to the department of animal husbandry.

Louisiana Station.—Working along the lines indicated editorially last November (E. S. R., 79, p. 433), two new varieties of strawberries have been developed. By crossing Blakemore and Klondike, resistance to leaf spot and a higher percentage of sugar have been obtained, as well as increased earliness. Improvements have also been effected in the yield of sweet corn, length of cotton staple, and wilt resistance, and in other directions.

R. H. Lush, in charge of dairy research, has resigned to accept a position with the National Fertilizer Association. His headquarters will be in Washington, D. C.

Maine University and Station.—The university has recently purchased a farm for the use of the station at Presque Isle. The new purchase abuts Aroostook Farm and contains approximately 100 acres, of which about half is under plow. The remainder is in woods and when cleared will be for the most part suitable for potato production. The farm land, which becomes available to the station on November 1, will be used for plat work in studies with potatoes and other crops of Aroostook County.

Montana Station.—L. A. Clark has been appointed assistant agronomist in cooperation with the U. S. D. A. Bureau of Plant Industry.

Nebraska Station.—Two pieces of special equipment have been purchased recently. One of these is a photometer for work in human nutrition and the other a sprayer which will develop considerable pressure and seems to be necessary in the control of potato psyllids.

Oregon Station.—A budget increase of \$157,500 for special agricultural research projects during the coming biennium was further enlarged by the legislature to \$172,400.

Pennsylvania College and Station.—Two new buildings constructed under the Federal P. W. A. program are nearing completion. One of these is the agricultural engineering building, a three-story structure of brick and limestone, which was dedicated May 10. The other is the new Frear Chemical Laboratory, also a three-story building, which is to be occupied early in the summer by the department of agricultural and biological chemistry.

Utah College and Station.—Dr. Leonard H. Pollard, associate in truck crops in the University of California, has been appointed head of the department of vegetable crops. Dr. A. E. Brandt, senior mathematical statistical analyst of the U. S. D. A. Soil Conservation Service, will serve as special guest professor of mathematics in the summer school, teaching courses in statistics and in the design of experiments.

International Congresses.—The Seventh International Congress of Genetics will be held in Edinburgh August 23-30, 1939. Sections are contemplated on gene and chromosome theory, cytology, physiological genetics, animal breeding in the light of genetics, plant breeding in the light of genetics, human genetics, and genetics in relation to evolution and systematics. Particular prominence is to be given to the application of genetics in the breeding of livestock and plants. Smaller groups may also be organized. Prof. F. A. E. Crew, director of the Institute of Animal Genetics, University of Edinburgh, is general secretary.

The Third International Congress of Agricultural Engineering will be held in Roma from September 20 to 23, 1939, at the International Institute of Agriculture. The program of the Congress has been drawn up by the International Commission on Agricultural Engineering. Irrigation, drainage, and land reclamation works, provisions for hygiene and buildings in rural areas, production of motive power by means of new combustible materials, standardization of tests of agricultural machinery, applications of electricity in agriculture, agricultural engineering and its social implications, and scientific management in agriculture are the main subjects in the agenda. Additional information may be obtained from the Secretariat, Via Regina Elena, 86, Roma, Italy.

EXPERIMENT STATION RECORD

VOL. 81

AUGUST 1939

No. 2

THE ORGANIZATION OF AGRICULTURAL RESEARCH IN GREAT BRITAIN

These are days when questions of organization and reorganization are receiving much attention. Research is among the phases which are under scrutiny. In the United States a comprehensive study is under way by the National Resources Committee, and its report on Federal relations was recently discussed in these columns (E. S. R., 80, p. 577). In England a somewhat similar inquiry has been going on under what may be termed semiofficial auspices.

The findings in the British survey have been published in monograph form under the title of Report on Agricultural Research in Great Britain: A Survey of Its Scope, Administrative Structure and Finance, and of the Methods of Making Its Results Known to Farmers, With Proposals for Future Development. This report embodies the results of a survey of over 3 years' duration which was conducted by the research group of P E P (Political and Economic Planning). P E P is described as "an independent nonparty group, consisting of more than a hundred working members who are by vocation industrialists, distributors, officers of central and local government, scientists, doctors, university teachers, and so forth and who give part of their spare time to the use of their special training in fact finding and in suggesting principles and possible advances over a wide range of social and economic activities." Its research division, whose identity is not further revealed in the report, has been making a survey of the use of organized science in the United Kingdom, and agricultural research was selected as the first phase of its study.

In Great Britain agricultural research is controlled by a complex group of central governmental officials. In general, grants of public funds are made by the Development Commission with the advice of the Agricultural Research Council and administered by the Ministry of Agriculture in England and Wales and the Department of Agriculture for Scotland. The bulk of the actual research is carried on by specialized research institutes, although both the Ministry of Agriculture and the A. R. C. conduct some research directly. Then there are 17 provincial advisory centers, where advisory officers in 6 of the agricultural sciences are stationed. The final link with the farmer is provided by advisory services under an agricultural organizer in each county.

About 50 institutions carry on research. Some of these are primarily educational in purpose with research as a byproduct, but in about 28 research is the paramount consideration. These include three types—government laboratories or research stations, institutions attached to universities or colleges, and institutes such as Rothamsted and the John Innes Horticultural Institution. All of these are to a greater or lesser degree dependent on grants from the Development Fund and its replenishment and supplementing by Parliament from time to time. There are also two imperial institutes and nine imperial bureaus which are financed collectively by the Governments of the British Empire, and provide an information and abstracting service in the subjects of entomology, mycology, soil science, animal health, nutrition and genetics, plant genetics, fruit production, agricultural parasitology, and dairying. These bureaus are located at the research institutes and are under the same director. In addition to this public support, perhaps 10 percent of the total research is carried on without any state subsidy at universities, agricultural colleges, and farm institutes, and by private firms, societies, and individuals.

The total annual expenditure from public funds for agricultural research in Great Britain is estimated as at least £700,000. This is considerably less than 1 percent of the total output of the land, and is regarded as inadequate. It is suggested, however, that in a program of enlargement, "though it is only right that the lion's share of the expense should be borne by the state, the wide range of interests on which agricultural research confers material benefits should also contribute, and to a greater extent than they do at present." The principal additional sources of revenue which are considered are (1) the products of research, (2) the farming community, and (3) processors, distributors, etc. It is thought that "more might be made out of the sale of the research institutes' own wares in the shape of royalties on new breeds and processes, fees for tests and educational training, and ordinary farming profits." Then, too, it is claimed, "farmers themselves contribute strikingly little toward the cost of research which is primarily for their benefit, yet a large sum could be raised by a comparatively small levy or contribution per acre." Therefore, "the possibilities of levies on products as means of raising funds for agricultural research might be further explored. . . . Where imports of agricultural produce are controlled, the joint interests of consumer and producer might be served by imposing a small levy and earmarking the proceeds partly or wholly for agricultural research. In other parts of the Empire, notably India, Ceylon, and Malaya, levies on exports have successfully been used to finance research, for example on rubber and tea."

Mention is also made of another class of beneficiaries from the results of agricultural research, who are "by no means pulling their weight and who might well be asked to contribute more toward its cost." These "are the processors and distributors of agricultural produce and the manufacturers of agricultural equipment. The processors and distributors include sugar refiners, butchers, millers, bakers, brewers, maltsters, and dairymen. Of these only the sugar refiners have made any organized large-scale provision for research, though the millers and certain large dairy firms have made minor grants. The dairy firms also maintain extensive laboratories of their own. The manufacturers of agricultural equipment, especially fertilizers, feeding stuffs, insecticides, veterinary preparations, and agricultural machinery, also owe much to the discoveries of research workers and might well consider repaying some of their debt. All these industries might well consider making, in addition to ad hoc grants toward pieces of research likely to result in immediate material benefit, regular contributions which might be earmarked to particular branches of research, but would be a token of the general benefits gained by the industry from research."

The report makes it plain that the problem of finance is closely bound up with that of personnel. It criticizes the prevailing scale of salaries as too low, especially in veterinary work, where the able younger man who "undertakes work of national importance in combating diseases of livestock or poultry is unduly heavily penalized for not going into private practice and attending to the ailments of lap dogs. . . . It is no economy to cut salaries below the level at which men of sufficient caliber can be attracted and kept in the service without feelings of frustration. Agricultural research needs men with initiative and resource, with high mental capacity, and with the imagination to grasp the practical needs of a varied industry which has not learned to think in scientific terms or to formulate its own requirements. The number of such men at present in the ranks is too small; it is creditable in the circumstances that there should be as many as there are. Some of the men who ought to supply vigor and leadership either refuse to enter a profession with such poor prospects or, having entered it, succumb to a justifiable dissatisfaction which eventually leads them to accept commercial offers or to sink into a rut."

Inevitably, considerable discussion is given of the problem of co-ordination of research. This function is entrusted chiefly to the Agricultural Research Council, organized for the purpose in 1931 and described subsequently in these columns (*E. S. R.*, 72, p. 578). The work of this body is commended, but it is stated that its activities are seriously handicapped by a shortage of personnel. As a means

of relieving the situation, the report suggests the appointment of special directors for the various branches of industry. These specialists would spend at least 3 months of the year visiting the research institutes and also make some visits to noted foreign research stations to compare methods used abroad. Among other duties they would keep complete "records of the problems requiring investigation and the work in progress [and] deal with the interchange of problems and information between the institutes to avoid overlapping and insure that field workers hear of the results of laboratory work as soon as they are available."

The final recommendation of the report takes up the utilization of research. Marked defects are indicated in the present system in the dissemination of findings, notably the absence of any provision for centralized coordination and direction. The establishment of a central body is advocated to act as a public relations and extension service. This service would coordinate research and extension and "might take over the responsibility for all official journals and other publications concerned with the agricultural sciences." The value of a separate body or department devoted wholly to this work would be that "the public relations of agricultural research would no longer be dependent on the time that busy scientists and administrators could spare from their proper jobs, and the extension services could be planned by men skilled in the art of putting results across. The volume of knowledge put forth by twentieth-century civilization is so vast and ramifying that without the oil of public relations work the complicated machinery of national and international relations is bound to get clogged. In agricultural research, as in other economic activities, a public relations policy is no longer an American novelty but a British necessity, while without an efficient extension service the whole research structure is stultified."

This report was obviously prepared to meet a specific situation and locality, and even its compilers probably had little thought of its application to other conditions. Nevertheless many principles of fundamental importance have been dealt with constructively. Its findings and their interpretation should be of interest to research administrators and workers in general.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations by the California Station] (*California Sta. [Bien.] Rpt. 1937-38, pp. 101, 102, 104-110*).—These have dealt with sulfuring difficulties with dried fruits; dried prunes, figs, and raisins; color in grapes and wine; wine types in California; fermentation of wines; use of Spanish sherry yeasts; oxidation of sherry wine; fruit and vegetable juices; other uses for surplus fruits and nuts; olive products; and plant pigments in fruits and vegetables.

[Chemical investigations by the Delaware Station] (*Delaware Sta. Bul. 214 (1938), pp. 19, 20*).—The extraction of phospholipids from soybean oil meal has been studied by A. A. Horvath, and factors affecting the viscosity or plasticity of pectin and pectin-sugar solutions as an index to jelly formation by G. L. Baker and M. W. Goodwin.

[Chemical investigations of the Florida Station] (*Florida Sta. Rpt. 1938, pp. 76, 77, 98-100*).—These are reported upon as follows: An improved colorimetric method for iron, by H. W. Winsor, and the preservation of orange juices and pulps, by A. L. Stahl.

[Chemical and bacteriological investigations by the New York State Station] (*New York State Sta. Rpt. 1938, pp. 12, 14, 15, 17*).—Work briefly noted has been concerned with the canning of apple and grape juice, prevention of lead contamination of maple sirup, influence of salts on the properties of gelatin, and aldehyde condensation products of amino acids and proteins.

[Chemical investigations by the Washington Station]. (Coop. U. S. D. A.). (*Washington Sta. Bul. 368 (1938), pp. 27, 28, 94-96*).—Fruit byproducts are reported upon by A. M. Neubert, H. H. Mottern, and J. L. St. John; apple products utilization, by Mottern, Neubert, and P. D. Isham; and soft fruit products utilization and vegetable products investigations, both by Neubert and Mottern.

Bacterial metabolism, M. STEPHENSON (*London and New York: Longmans, Green and Co., [1939], 2. ed., pp. XIV+391, figs. [46]*).—Originally published (E. S. R., 62, p. 707) as one of the Monographs on Biochemistry, this work is now felt to be unsuited to monograph form. "the exhaustive treatment of the whole subject by one author being now impossible." It is presented "in an enlarged form as an advanced textbook." The contents are introduction, respiration, polysaccharides, the fermentation of hexoses, the decomposition of proteins, the metabolism of nucleic acid, nutrition and growth, nitrogen fixation, autotrophic bacteria, bacterial photosynthesis, and enzyme variation and adaptation.

Photochemical studies of rancidity: The mechanism of rancidification, M. R. COE (U. S. D. A.). (*Oil & Soap, 15 (1938), No. 9, pp. 230-236, figs. 2*).—According to the theory here set forth, rancidification has its origin in a disrupted photosynthesis in the case of vegetable oils and the photosensitizing action of hemoglobin or other animal pigment that may be present in small amounts in animal fats such as lard. Nascent hydrogen is believed to be lib-

erated from the photosensitizer (chlorophyll or animal pigment) which unites with molecular oxygen to form loosely combined or nascent hydrogen peroxide. This unstable peroxide unites with the unsaturated bond of the triglyceride to form a glyceride peroxide which in turn splits into an aldehyde and forms the rancid compound. It is pointed out that this theory accounts for some phenomena heretofore not readily explained.

The author also shows that the ability of an oil to absorb added chlorophyll, combined with the appearance of its fluorescence, may be used to indicate the susceptibility of an oil to become rancid.

A rapid method for determining moisture in roughages, C. F. MONROE and A. E. PERKINS. (Ohio Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 1, pp. 37-39, fig. 1).—In the method described, samples are dried rapidly by forcing heated air through the material. Drying in this manner for from 10 to 30 min. gave results in close agreement with those obtained by the usual oven method of drying for 24 hr. at 100° C.

Determining salt content of cheese, O. R. OVERMAN and B. F. WHITMORE. (Univ. Ill.). (*Natl. Butter and Cheese Jour.*, 30 (1939), No. 2, pp. 18, 34, 35).—A method is described for determining the salt content of cheese, in which the sample of cheese is digested in strong sulfuric acid in a side-arm distilling flask and the liberated hydrogen chloride absorbed in a measured volume of a standard solution of silver nitrate. The results obtained by this method checked closely with those found by the official method, and its use in commercial laboratories seemed preferable because of its simplicity and rapidity in manipulation.

A micromethod for the determination of iron in blood, R. BREUER and W. E. MILLTNER. (Univ. Nebr.). (*Jour. Biol. Chem.*, 126 (1938), No. 2, pp. 561-566).—Fading of ferric thiocyanate is caused by the evolution of hydrogen sulfide from the decomposition of the thiocyanate ion. This reduces the ferric ion to the ferrous ion, which gives no color with thiocyanate. The decomposition is hastened by light and by a strong acid medium. The color can be stabilized for several hours even in strong acid by placing the solutions in the dark and by adding an oxidizing agent to oxidize the hydrogen sulfide. The stabilizers that have been mentioned in the literature are nitric acid and potassium persulfate. Of the oxidizing agents tried, potassium persulfate was best, since it has only a small tendency to oxidize the thiocyanate to free sulfur. Hydrogen peroxide was also satisfactory but had a greater tendency to produce free sulfur.

The method described involves oxidation of the blood sample with potassium permanganate in the presence of sulfuric acid, decolorizing of the excess permanganate by hydrogen peroxide, and colorimeter comparison of the thiocyanate color with that of a standard thiocyanate prepared by a like method. The procedure requires 0.1 cc. of blood. The data given show recoveries of from 92.5 to 98 percent of the iron present.

Maple syrup making object of study, C. O. WILLITS (*Farm Res. [New York State Sta.]*, 5 (1939), No. 2, pp. 1, 2).—Methods of manufacture of maple sirup and sugar are very briefly outlined, with some possible improvements, and suggestions as to the future of the manufacture of these products in New York State.

Sugar and starch products from corn, W. B. NEWKIRK (*Contrib. Iowa Corn Res. Inst. [Iowa Sta.]*, 1 (1939), No. 2, pp. 213-218).—This is a summary of progress already made in the development of industrial uses of cornstarch and sugar and their modifications and derivatives and of work still in progress.

Possibility of a domestic root starch industry, H. G. KNIGHT. (U. S. D. A.). (*Contrib. Iowa Corn Res. Inst. [Iowa Sta.]*, 1 (1939), No. 2, pp. 219-222).—This is an address largely occupied with outlining the work of the U. S. D. A. Bureau of Chemistry and Soils on production of good quality starch free from yellow color from sweetpotatoes. It is pointed out that the product made in the experimental plant of the bureau meets the root-starch demands of various industries.

The production of caproic and butyric acids by the methane fermentation of ethyl alcohol, H. A. BARKER. (Univ. Calif.). (*Arch. Mikrobiol.*, 8 (1937), No. 4, pp. 415-421, fig. 1).—The author reports upon a fermentation of ethyl alcohol under the influence of *Methanobacterium omelianskii* and an associated spore-forming bacterium, the alcohol being converted into acetic, butyric, and caproic acids, with a concomitant reduction of carbon dioxide to methane. The data indicate the formation of butyric and caproic acids by a condensation of a C-compound which probably is acetaldehyde.

Effect of temperature of digestion, chemical composition, and size of particles on production of fuel gas from farm wastes, G. H. NELSON, R. P. STRAKA, and M. LEVINE. (U. S. D. A.) (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 4, pp. 273-287, figs. 3).—The rate and quantity of gas produced by the anaerobic decomposition of chopped cornstalks, chopped wheat straw, ground wheat straw, cornstalk flour, filter paper, seed flax straw, artichoke-top flour, cook liquor from wall board manufacture, and alkali lignin were determined at from 28° to 30° and from 50° to 55° C. With artichoke-top flour and seed flax straw, the rate of digestion at from 28° to 30° was not appreciably different from that at from 50° to 55°. With filter paper and cook liquor the same quantity of gas (300 cc. per gram of volatile solids) was produced in about one-third of the time at from 50° to 55°. With cornstalk flour and chopped wheat straw it required approximately half as long to produce 300 cc. of gas at 55° as at from 28° to 30°. With ground wheat straw the digestion time was reduced about one-third by employment of the higher temperatures, while with chopped cornstalks only about one-quarter of the digestion period was necessary at from 50° to 55° as at from 28° to 30° to produce the same amount of gas. The effect of temperature on the rate of digestion of fibrous farm wastes was more marked with coarser materials, such as chopped cornstalks and chopped wheat straw, than with finer materials, such as cornstalk flour and ground wheat straw.

AGRICULTURAL METEOROLOGY

[Papers on meteorology at the nineteenth meeting, American Geophysical Union] (*Amer. Geophys. Union Trans.*, 19 (1938), pt. 1, pp. 154-156, 159-171, 172, 173, 174-176, figs. 42).—The following are of interest to meteorology: Measurements of Ultra-Violet Solar Radiation in Puerto Rico, by G. W. Kenrick and H. Ortis (P. R. Col. Expt. Sta.); A Year of Ultra-Violet Measured with a Dosimeter at Blue Hill, by D. L. Arenberg; The Meteorological Aspects of Certain Radio-Transmission Phenomena, by G. W. Kenrick and G. Lavergne (P. R. Col. Expt. Sta.); Progress in Compiling and Summarizing Ships' Weather-Observations, by I. R. Tannehill (U. S. D. A.); Meteorological Research Contemplated for an Expedition to North Greenland, by M. Demorest; The Velocity of Sound-Waves From Gun-Fire in Southern California, by B. Gutenberg; Solenoidal Circulations [of the Atmosphere] Resulting From Lateral Mixing, by C.-G. Rossby; The Intensity of Lateral Mixing in the Atmosphere as Determined From Isentropic Charts, by G. Grimminger (U. S. D. A.);

Wave-Distribution in a Homogeneous Current [Atmosphere and Ocean], by C. L. PEKERIS: Mean Monthly Isentropic Charts and Their Relation to Departures of Summer Rainfall, by H. Wexler and J. Namias (U. S. D. A. et al.); On the Thermodynamic Interpretation of Isentropic Charts, by H. R. Byers, and On the Use of Isentropic Cross-Sections, by C. H. Pierce (both U. S. D. A.); Characteristics of the Littoral Water and Weather Along the Pacific Coast of Colombia and Ecuador, by R. C. Murphy; and The Forecasting Significance of Anticyclonic Eddies on the Isentropic Chart, by J. Namias.

Monthly Weather Review, [November–December 1938] (U. S. Mo. Weather Rev., 66 (1938), Nos. 11, pp. 351–399, pls. 9, figs. 15; 12, pp. 401–442, pls. 11, figs. 7).—In addition to the usual detailed summaries of climatological data, solar and aerological observations, observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and bibliographical and other information, these numbers contain the article noted on page 169 and the following contributions:

No. 11.—Sounding-Balloon Observations Made at Omaha, Nebr., During the International Months June 1935, November 1936, and August 1937, and Winds Observed During July 1937, by J. C. Ballard (pp. 360–375); Distribution of Air-Mass Types and Frequency of Change in the Western United States During 1937–38, by A. C. Gerlach (pp. 376, 377); and West Indian Disturbance of November 6–10, 1938, by W. E. Hurd (p. 376).

No. 12.—A Solution to the Problem of Adjusting the Counterbalance of a Shipboard Theodolite, by A. R. Stickley (pp. 401–412); Preliminary Reports on Tornadoes in the United States During 1938, by J. P. Kohler (pp. 412–414); and North Atlantic Tropical Disturbances of 1938, by W. E. Hurd (pp. 414, 415).

[Meteorological studies and observations by the Florida Station]. (Partly coop. U. S. D. A.). (Florida Sta. Rpt. 1938, pp. 129–136, 149–151, 174, 175, figs. 3).—Brief reports are given relative to the horticultural protection service, including temperature surveys, forecast and frost warning service, and distribution and accuracy of forecasts, by E. S. Ellison; water control experiments, and meteorological records at the Everglades Substation; and meteorological records, and climatic factors in relation to crops at the North Florida Substation.

A density channel for illustrating fronts and occlusions, B. C. HAYNES (Bul. Amer. Met. Soc., 20 (1939), No. 2, pp. 37, 38, figs. 7).—An apparatus for demonstrating and illustrating meteorological fronts and occlusions is described, the density channel consisting of plate glass sides, fitted with metal heating pads on the floor and measuring 30 by 4 by 6 in.

Some long-range forecasting methods and activities in Europe, I. I. SHELL (Bul. Amer. Met. Soc., 20 (1939), No. 2, pp. 44–48).—A review of recent research and results in long-range forecasting, with special reference to Germany, Russia, and England.

Atmospheric ozone as a possible meteorological factor, C. L. PEKERIS. (U. S. D. A. et al.). (Bul. Amer. Met. Soc., 20 (1939), No. 1, pp. 3–10, figs. 8).—An attempt is here made to survey the existing evidence (18 literature references) for correlations between variations in atmospheric ozone and the state of the stratosphere and of the troposphere.

Evaporation from the land surfaces of the earth in relation to temperature and precipitation [trans. title], W. WUNDT (Ztschr. Angew. Met., Wetter, 56 (1939), No. 1, pp. 1–9).—The annual evaporation from the land surfaces of the earth in relation to precipitation and mean temperature is presented in tabular form and discussed, including the methods used in obtaining and interpreting the data.

Temperature and vapor pressure as factors in tornadic inception in eastern Nebraska, H. LEMONS. (Univ. Nebr.). (*Bul. Amer. Met. Soc.*, 20 (1939), No. 2, pp. 49, 50).—The records presented and discussed are believed to indicate the possibility of a relationship of temperature and vapor pressure with tornadic inception but not the inference that such relationship always exists.

Weather preceding forest fires in New Hampshire, L. LANSING (*Bul. Amer. Met. Soc.*, 20 (1939), No. 1, pp. 10–26).—Close analyses of the weather conditions preceding five dates on which large or numerous fires occurred definitely indicate that certain combinations of such conditions have been typical when large fires have occurred. On the basis of the results reported special precautions are indicated following a precipitation deficit of ± 70 percent or more for 7–10 days combined with a high percentage of clear weather (70 percent or more of the possible sunshine), low relative humidity (below 65 percent at 8 a. m., and below 45 percent at noon), high winds for several days, and above normal maximum temperatures.

Considerations of phenological practice [trans. title], A. A. ORTIZ (*Jor. Agron. y Vet., Univ. Buenos Aires*, 1937, pp. 115–123).—The author presents his general concept with a system of procedure as a basis for practical phenological studies, including the general climate, climatic variants with latitude and altitude, and agricultural climates and regions.

Bioclimatics: The what and why, E. N. MITUNNS (*Chron. Bot.*, 5 (1939), No. 1, pp. 5–8).—An analysis, based on Hopkins' work (*E. S. R.*, 78, p. 753), of this hardly scratched field of scientific research of great potential service to forestry, agronomy, horticulture, soil science, economic entomology, plant pathology, and other fields of applied biology.

Climatic research in the Soil Conservation Service, C. W. THORNTHWAIT, B. HOLZMAN, and D. I. BLUMENSTOCK (*U. S. Mo. Weather Rev.*, 66 (1938), No. 11, pp. 351–368, figs. 11).—"Climatic work carried on as an integral part of the research program of the Soil Conservation Service has clearly demonstrated the need for a variety of specialized climatic investigations into soil erosion problems. Many of these climatic problems have already been undertaken, several have been completed, but there are still numerous questions which, while clearly recognized, have yet to be subjected to study. General climatic considerations are useful in defining 'erosion regions' and in treating the element of climatic risk. Analyses of precipitation records in terms of storm duration, intensity, and storm area have been undertaken and are being directly related to field phenomena. Drought is being considered as a type of climatic risk particularly significant in the Great Plains and the semiarid West. Temperature in its bearing on climatic risk and weathering processes is also being scrutinized. Likewise, a consideration of the flood problem in its bearing on erosion hazards requires studies of excessive precipitation, actual evaporation from various types of land surfaces, and soil-moisture deficiency. Thus, in a wide variety of ways, a number of climatic studies are being carried out. That climate is an inseparable major theme in the soil erosion complex is clear. The objective is to orient the climatic work in such a way that results of maximum practical value will be obtained."

SOILS—FERTILIZERS

[Soil investigations by the California Station]. (Partly coop. U. S. D. A.). (*California Sta. [Blen.] Rpt.* 1937–38, pp. 2–9, pls. 2).—These are noted briefly under the captions natural land classifications, cover crops prove efficient in erosion control, use of mechanical controls, drainage problems again trouble-

some, alkali lands reclaimed, soil permeability studies, and irrigation and soil salts.

[Soil investigations by the Delaware Station] (*Delaware Sta. Bul.* 214 (1938), pp. 20, 21, 45).—The effect of degree of base-saturation upon the fixation and availability of phosphorus and potassium in soils is dealt with by G. M. Gilligan; and work on the influence of minor elements on the soil flora is reported by T. F. Manns and R. Russell.

[Soil and fertilizer work of the Florida Station] (*Florida Sta. Rpt.* 1938, pp. 140–142, 153, 154, 156, 157, 169, 170).—The following topics are briefly discussed: Nutrient salt concentration in the soil, with special reference to the trace elements, by R. B. French; citrus soils investigations, by M. Peech; soils investigations, including water-holding power, green manuring, loss of soil by oxidation, and the role of special elements in the Everglades, by J. R. Neller and W. T. Forsee; physiological phases of plant nutrition, with special reference to moisture and aeration relation and phosphorus content, by Neller; and relation of organic composition of crops to growth and maturity, by Forsee.

[Soil investigations by the Washington Station]. (Partly coop. U. S. D. A. et al.). (*Washington Sta. Bul.* 363 (1938), pp. 17–22, 89–91).—The following topics are briefly reported upon: Fertility investigations of Washington soils, by L. C. Wheating, S. C. Vandecaveye, and L. E. Dunn; the maintenance of organic matter in eastern Washington soils, by Vandecaveye, Wheating, and L. T. Kardos; hardpan formation in the irrigated soils and changes occurring in irrigated soils as a result of irrigation, cropping, and fertilizer treatments, both by Wheating and Vandecaveye; fertility of irrigated soils, by Vandecaveye, Wheating, and H. P. Singleton; maintenance of organic matter in central Washington, by Wheating, Vandecaveye, and H. D. Jacquot; investigations of the effect of accumulations of arsenical sprays in orchard soils, by Kardos, Vandecaveye, and C. M. Keaton; and fertility investigations of greenhouse soils, by Wheating and Dunn.

From the Soil Conservation Substation brief reports on effect of plant cover on run-off and erosion, movement and balance of soil moisture, cropping practices in relation to erosion control, and tree planting for erosion control are contributed by G. M. Horner, and tillage and cultivation practices for erosion control and terracing studies, by Horner and L. M. Naffziger.

A mixer and sampler for greenhouse soils, R. L. Cook. (*Mich. State Col.*). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 2, pp. 171–174, fig. 1).—The mixer consists of a 15-in. cubical sheet metal box with rounded corners and with a 0.5-in. steel shaft passing through diagonally opposite corners. A crank on one end of the shaft is used to turn the mixer. The cover, consisting of about three-fourths of one side of the mixer, is on hinges and is fastened by means of screw clamps which slip apart as soon as they are loosened. A rubber gasket keeps the soil from sifting out. To hasten the mixing, two 3-in. triangular baffle plates are welded into the edges opposite the cover and half way between the corners. These plates carry a portion of the soil up and allow it to fall on the remainder.

The sampler consists essentially of a square funnel 16 in. at the top and 3 in. at the bottom and a pyramid 17 in. high with a 12-in. square base. The funnel is fitted with a slide to hold the soil. The edges of the pyramid are turned out a distance of 1.5 in., and one side is fitted with a piece of metal so arranged as to direct soil into a small tray. The height of the frame (1.5-in. angle iron) is 38 in., the funnel coming down over the top of the pyra-

mid. When the slide is quickly removed the soil is divided into four almost equal portions, of which one is caught and returned to the funnel for another quartering.

Soil analysis: A handbook of physical and chemical methods, C. H. WRIGHT (London: Thomas Murby & Co.; New York: D. Van Nostrand Co., 1939, 2. ed., pp. X+276, figs. 10).—Additions to the methods presented in the first edition (E. S. R., 71, p. 591) include the freezing point, the glass electrode, the antimony electrode, inorganic soil colloids, and the determinations of zinc and cobalt in soils. The analysis of the clay fraction and the determinations of calcium and exchangeable potassium have been entirely rewritten. By abbreviation of many passages and the omission of some methods either out-of-date or of minor importance the author has avoided any great increase in the size of the book. The contents are an introduction, part 1 on physical methods, part 2 on general chemical methods, part 3 on special chemical methods, and appendixes giving related data and factors, together with author index and subject index.

Determining by plant response the retention of nutrient ions by soils, J. P. CONRAD and C. N. ADAMS. (Univ. Calif.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 1, pp. 29-34, fig. 1).—The authors describe an experimental technic consisting essentially in arranging three or more pots of soil one above another, allowing the solution of the nutrient the absorption of which should be tested to percolate through and drop from the pots in succession, and determining by growing a test crop in each pot in which of the pots the nutrient was retained in a quantity sufficient to affect plant growth.

Experiments of this nature indicated that the nitrate ion is not retained, whereas the ammonium ion as supplied either by ammonium hydroxide or by ammonium sulfate remained in the uppermost layer of the soil. Sodium nitrite produced a uniform toxicity in the first planting, followed by uniformly good growth of a planting made 8 days later after time for oxidation to nitrate had elapsed. The phosphate ion as supplied by sodium hydrogen phosphate was absorbed in the top pot to such a degree that the growth of milo in the top pot was between four and five times that occurring in either the second or the third. Treatment of a sulfate-deficient soil by percolation with sodium sulfate solution showed no evidence of retention in any of the three pots.

St. Clair County soils, G. D. and L. H. SMITH (*Illinois Sta. Soil Rpt.* 63 (1938), pp. [1]+36, figs. 9, maps 3).—This adds 426,000 acres to the total area examined in the State soil survey (E. S. R., 80, p. 12).

Soil survey of Wheeler County, Nebraska, B. ABASKIN and F. A. HAYES. (Coop. Univ. Nebr.). (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpt.]*, Ser. 1933, No. 5, pp. 35, fig. 1, map. 1).

Land facts on the southern plains, G. K. RULE (*U. S. Dept. Agr., Misc. Pub.* 334 (1939), pp. [4]+22, figs. 13, map. 1).—This is a nontechnical description of the soil conditions and needs found and the treatments demonstrated in region 6 (the southern Great Plains) by the Soil Conservation Service. An attached map covering 10 problem-area groups "represents the first attempt to isolate and label those bodies of land where the soil, climate, and appropriate farming practices are somewhat similar."

Problem-area groups of land in the southern Great Plains, H. H. FINNELL (*U. S. Dept. Agr., [Soil Conserv. Serv.]*, 1939, pp. [1]+40, map. 1).—For each of the problem-area groups mentioned there are given approximate acreage, description of the physical factors of soils, physiography, and the erodibility of the soils, together with recommended conservation practices, including crop management, land retirement, soil management, water conservation, and other

measures appropriate to the individual land type. An appendix shows, in tables, the acreage, distribution, present use, principal physical factors, and degree of erosion in each problem-area group, and the recommended land use adjustments and water-conservation measures in each State for all problem-area groups.

Erosion and related land use conditions on the Minot area, North Dakota. N. HOLOWAYCHUK and W. C. BOATRIGHT (*U. S. Dept. Agr., [Soil Conserv. Serv.], (1938), pp. [1]+37, pls. 3, figs. 6, maps 5*).—The area here dealt with comprises four counties in northern North Dakota and contains 4,174,080 acres, the most erodible soils being the dune sands and the light-textured Thurman soil series.

No apparent erosion was found on 15.7 percent of the area, slight erosion on 67.3, moderate on 12.5, severe on 2.8, and very severe erosion on 1.7 percent. Wind erosion is more serious than water erosion. Most of the serious wind erosion has occurred on the light-textured soils and wind-erosion control practices are most essential, but water-erosion control practices, also necessary, will provide at the same time for moisture conservation. Serious water erosion is found on sloping areas of medium- and light-textured soils. Moderate wind and water erosion occurs on medium- and heavy-textured soils on level land. Nearly all serious erosion is on cultivated or idle land.

An unusual alkali soil. W. P. KELLEY and S. M. BROWN. (Calif. Citrus Expt. Sta.). (*Jour. Amer. Soc. Agron., 31 (1939), No. 1, pp. 41-43*).—The titration behavior of a water extract of the soil, described after neutralizing the separate samples of the extract with standard acid to the end point of phenolphthalein and of methyl orange, respectively, together with a determination of the pH value of the extract (10.75) and its content of various anions and cations (the latter consisting predominantly of sodium), showed that the soil owes a considerable proportion of its alkalinity to sodium silicate. A 1:5 water extract contained 374.9 mg. per liter of silicon calculated as the dioxide as against 255 mg. per liter of the carbonate ion as CO_3 .

The soil was found at Vale, Oreg. "The exceptional feature of this soil is that it contains a substantial amount of sodium silicate in addition to soluble carbonate and the other salts common to alkali soils. Although it is common to find soluble SiO_2 in black alkali soils, the amount is usually small. This Oregon soil, however, contains relatively much soluble silica. Therefore, the geological and pedological history of this soil is a matter of some interest."

Observations regarding soils of northern and central Mexico. J. T. MILLER and I. C. BROWN. (*U. S. D. A., [Soil Sci., 46 (1938), No. 6, pp. 427-451, pl. 1, fig. 1]*).—The authors describe six profiles of zonal and intrazonal soils, presenting the results of chemical analyses of the various horizons and of their colloids, the data including percentages of silica, iron, aluminum, magnesium, calcium, potassium, sodium, titanium, and manganese as the oxides, phosphoric and sulfuric anhydrides, loss on ignition, organic matter as determined by a combustion method, carbon dioxide content of the soil carbonates, and nitrogen. Soluble salts and selenium are given in parts per million. The pH values were determined by hydrogen electrode and by glass electrode methods.

The authors found that these six soils have their counterparts in the United States with respect to both profile development and character of colloid present. "In Mexico the great soil groups are represented in a comparatively limited area. This is due to the great differences in local relief and the attendant differences in climate and vegetation."

Soil improvement in the Sudan Gezira. H. GREENE and O. W. SNOW (*Jour. Agr. Sci. [England], 29 (1939), No. 1, pp. 1-34, figs. 4*).—Ferrous sulfate, calcium sulfate, potassium sulfate, and sulfur, used in conjunction with ammonium

sulfate, effected temporary increases in water penetration, nitrogen supply, and yield, but the improvements were not permanent.

Saltbush analyses indicated that this plant removes much sodium from the soil, but that its use could not be expected to effect practical improvement in a soil of comparatively high sodium content. "On the other hand, it appears that by including saltbush in rotation and by removing the crop from the land it is possible to guarantee that no progressive deterioration will occur in consequence of accumulation of sodium introduced in the irrigation water."

Physical characteristics of soils.—II, Expressing mechanical analysis and state of aggregation of soils by single values, A. N. and B. R. PURI (*Soil Sci.*, 47 (1939), No. 1, pp. 77-81, figs. 3).—In continuation of a previous study (E. S. R., 79, p. 17), the author points out that there are three "single-value" constants derivable from the summation or distribution curves obtainable in the mechanical analysis of soils, namely, the weighted mean size, the standard deviation (σ), and a constant based upon the fact that "if . . . the area A lying above and to the left of the summation curve is divided by the area B lying below and to the right of the summation curve, the fraction A/B remains constant as long as the limit 0 and 1 remains unaltered. . . . The constant is referred to as the Schoklitsch number, or K, and when not otherwise specified is taken to refer to diameters lying between 0 and 1 mm." The authors consider that these values should replace the descriptive terminology generally employed for characterizing soil texture. State of aggregation can be satisfactorily expressed by the ratio of these single values before and after dispersion of the soil.

A critical survey of investigations on the "wilting coefficient" of soils, J. V. BOTELHO DA COSTA (*Jour. Agr. Sci. [England]*, 28 (1938), No. 4, pp. 630-643).—In a review of contributions on this subject the author finds the original conclusions (1) that the wilting coefficient is independent of the kind of plant used as indicator, and (2) that the coefficient is independent of ordinary variations of growth to be substantiated by subsequent work; but the assumption that the wilting coefficient is directly related to other soil constants has been exploded. Conclusions (1) and (2) "are substantially correct for hygrophytes and mesophytes." It is further noted that "an important factor making for the substantial constancy of the wilting coefficient for a given soil is the extreme steepness of the curve connecting suction pressure and soil moisture content, in consequence of which differences of suction pressure of unquestionable significance from the standpoint of plant physiology give rise to differences in soil moisture content that are too small to be detected."

The indirect determination of the "wilting coefficient" by the freezing-point method, and the influence of the salts upon the pF at that critical moisture content, J. V. BOTELHO DA COSTA (*Jour. Agr. Sci. [England]*, 28 (1938), No. 4, pp. 654-662, figs. 2).—The pF at the wilting coefficient, as measured by the modified freezing-point method, varied from 4 to 4.4, approximately, with an average of 4.2.

"The variation observed bears no relation to the soil texture, neither can it be explained by uncertainties in the freezing-point determinations which have proved to be accurately reproducible. Freezing-point measurements after leaching, conductivity measurements, and freezing-point determinations in saturated soil and at the moisture equivalent proved that part of the variation is due to the presence of soluble salts, the more saline soils having a higher pF at the wilting coefficient. When the salt content does not exceed about 500 p. p. m. the influence of the salts is hardly detectable, and the pF at the wilting coefficient lies between 4 and 4.3." Because of unavoidable errors in the wilting

experiments and other factors, "a variation of 0.3 pF units can be considered very small. It can therefore be confidently concluded that in ordinary agricultural soils with a salt content of less than about 500 p. p. m. permanent wilting occurs when a critical pF value (lying between 4 and 4.3) is reached."

The measurement of pF in soil by freezing-point, R. K. SCHOFIELD and J. V. BOTEELHO DA COSTA (*Jour. Agr. Sci. [England]*, 28 (1938), No. 4, pp. 644-653, fig. 1).—The authors describe two modifications of the procedure of Bouyoucos and McCool (*E. S. R.*, 34, p. 721), of which the first employs three separate freezing mixtures and other elaborations to provide a more delicate control of the degree of supercooling and to minimize the cooling due to surroundings while freezing is in progress. The second procedure is substantially the same as that used by Bouyoucos and McCool.

Determination of the weight of water in a soil or subsoil mass in which the moisture content increases with distance from a plant or group of plants, M. L. JACKSON and M. D. WELDON. (*Nebr. Expt. Sta.*). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 2, pp. 116-127, figs. 9).—With the plant at the origin and with the use of polar coordinates, the authors derived equations for the summation of the water content of squares in the case of equal spacing of rows and of plants in the row, rectangles when the rows are farther apart than the plants in the row, and hexagons in the case of alternate spacing. The derivation given involved successive integrations with respect to two variables, but the solution is in terms of definite integrals giving in each case a final formula the use of which involves only simple arithmetic.

Snow ridging to conserve moisture and decrease erosion, H. F. MCCOLLY and W. H. FARMER (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 4, pp. 32-35, fig. 1).—The authors found that the use of snow plows and crowdors to build up ridges 18 in. high from a 5-in. snowfall resulted in holding much snow on the fields, while similar areas not ridged were blown clean of snow after a thaw freeze and second drifting fall of snow. With falls of less than 5 in. the authors consider that a second ridging may be necessary to build up ridges of a sufficient depth. The best results were obtained by ridging at a temperature high enough to make the snow damp. The ridges should not be more than 8 ft. apart if they are to prevent wind removal and on level ground should be made across the prevailing direction of the wind. On rolling ground, however, contour ridging should be practiced. Not only did the ridges hold snow from blowing but the ice strips formed under the ridges helped to prevent draining off of water during thaws.

Equipment suggested included a push plow driven by a large tractor capable of drawing two pull plows offset back of the drawbar. Less elaborate plows can be made in a good farm shop at a cost of about \$25 even when all material must be bought new.

Soil temperatures under 6, 12, and 24 in. of snow are recorded.

The mechanism of cation exchange in the montmorillonite-beidellite-nontronite type of clay minerals, J. E. GIESEKING. (*Ill. Expt. Sta.*). (*Soil Sci.*, 47 (1939), No. 1, pp. 1-13, pl. 1, figs. 4).—Minerals of the montmorillonite-beidellite-nontronite type were found to adsorb large substituted ammonium ions, giving rise to (001) spacings greater than those of the same minerals saturated with such smaller cations as calcium or hydrogen. The diffracted radiation from the (001) planes of these minerals, treated with the complex cations, was much more intense than the same diffraction from the calcium and hydrogen systems. A gradual increase in the amount of complex cation added to montmorillonite systems resulted in increases in (001) spacings and intensity

of diffraction from these planes to a maximum. These results indicated that a portion of the complex cations were adsorbed within the variable (001) spacings of the minerals.

The large complex cations used in this investigation were very strongly adsorbed by montmorillonite. They were found to be exchanged by other cations of approximately the same size, but they were not exchanged by hydrogen, which is very effective in replacing small cations. The substituted ammonium cations were found to be very effective in flocculating the dispersed clays. Montmorillonite saturated with the large substituted ammonium ions did not show the water adsorption, swelling, and dispersion characteristic of Ca-, Na-, and H-montmorillonite. The (001) spacings of the complex ammonium systems did not vary with the water content of the system.

The stimulating effects of silicates on plant yields in relation to anion displacement, S. J. TORR. (N. J. Expt. Stas.). (Soil Sci., 47 (1939), No. 2, pp. 123-141, pl. 1).—The author reports an investigation of the displacement of adsorbed phosphate ions from Colts Neck loam, the displacing anions being the hydroxyl, the silicate, the silicate of pH 7, and the sulfate. A replacement of the adsorbed ions took place in solutions of anions that possess high pH values, namely, the hydroxyl and the silicate. Under this condition degradation of the phosphated soil complex resulted. The displacement of the adsorbed phosphate ion seemed to be independent of the silicate-ion concentration but was dependent upon the pH. The displacing anions were classified into two groups with reference to the mobilization of the phosphate ions. Group one contained the hydroxyl and silicate ions, group two the silicate at pH 7 and sulfate ions. The solutions of anions of the first group were associated with high pH values and large displacements of the adsorbed ion; the anions of the second group did not effect any marked release of the phosphate ion. A definite increase in yield of barley and Sudan grass was noted when these crops were grown on soil to which calcium or magnesium silicate was added. There was no relation between the available phosphate contents of the soils and yields from the pots. Slight changes in the SiO_2 , P_2O_5 , CaO , and MgO content of the crops when grown on silicated soils were noted. There was a very marked absorption of silica by rape, barley, and Sudan grass when these plants were grown on silicated soils.

Action of carbon dioxide on soils, A. N. PURI and H. L. UPPAL (Soil Sci., 46 (1938), No. 6, pp. 467-471).—The action of CO_2 on soils has been studied by following the changes in the pH values. The importance of CO_2 in the reclamation of alkali soils is brought out by the observation that CO_2 induces changes that are the reverse of those involved in the process of alkalization.

Chemical nature of organic matter in differently cropped arid soils, K. R. STEVENS. (Utah Expt. Sta.). (Soil Sci., 47 (1939), No. 1, pp. 27-31).—Samples taken from adjacent plats which had supported continuous fallow, oats, and alfalfa, respectively, for 25 yr. were somewhat high in the ether- and alcohol-soluble fraction. The "protein" and "lignin-humus" fractions were high. The carbohydrate fraction was unusually low. The ether- and alcohol-soluble and carbohydrate fractions decreased with depth for the three plats. The protein fraction decreased with depth for the fallow and oats plats but increased with depth for the alfalfa plat. The lignin-humus fraction increased with depth in the fallow plat but decreased with depth in the oats and alfalfa plats.

Bacteria in the soil (New York State Sta. Rpt. 1938, p. 12).—Observations of an inhibitive effect of air-dry storage of soil upon the subsequent growth of soil bacteria, an effect which may interfere with the use of micro-organisms as indicators of soil nutrient deficiency, are briefly noted.

Thermophilic actinomycetes and fungi in soils and in composts. S. A. WAKSMAN, W. W. UMBELT, and T. C. CONDON. (N. J. Expt. Stat.). (*Soil Sci.*, 47 (1939), No. 1, pp. 37-61, pls. 1).—The authors found thermophilic actinomycetes growing at 50° and at 65° C. and also at 28° abundantly in variously treated field soils, those receiving stable manure containing larger numbers of these organisms. The most abundant of the thermophilic fungi found belonged to the *Thermomyces*. It grew well at 50° but not at 65°, producing dark chlamydospores on short side branches. Among the thermophilic actinomycetes six distinct types were recognized, belonging to the two genera *Actinomyces* and *Micromonospora*.

Influence of temperature upon the microbiological population and decomposition processes in composts of stable manure. S. A. WAKSMAN, T. C. CONDON, and N. HILFOL. (N. J. Expt. Stat.). (*Soil Sci.*, 47 (1939), No. 2, pp. 83-113, pls. 1, figs. 3).—A temperature of 75° C. was found to be unfavorable to biological decomposition of horse manure. Only the hemicelluloses were decomposed to any considerable extent. The cellulose was not attacked at all, the increase in proteins was limited, and only a part of the lignin was brought into solution. The most rapid decomposition of the manure set in at a temperature of 65° followed by that at 50°. After the first stages of rapid decomposition the process was found to proceed more rapidly at 50° than at 65°.

At 25° there was a considerable delay before active decomposition set in, but after a lapse of 9 or 10 days the manure began to decompose rapidly as a result of the development of an extensive microbiological population. The groups of organisms active at these various temperatures are described.

The nitrogen in the manure was conserved only when immediate decomposition set in. This resulted in a rapid break-down of the carbohydrates and the transformation of the soluble nitrogen into insoluble forms. Whenever decomposition was delayed, either because of too low or too high temperatures, losses of the volatile forms of nitrogen occurred.

Leaching studies with various sources of nitrogen. N. BENSON and R. M. BAERNETT. (Fla. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 1, pp. 11-24).—The authors used small, percolation-type lysimeters to determine the leaching of nitrogen in the form of nitrate, nitrite, urea, and ammonia from Norfolk sand after treatment with several nitrogenous materials. An equivalent of 40 mg. of nitrogen was applied to 10 lb. of surface soil and placed in a pot on top of 20 lb. of moistened subsoil. The cultures were established and allowed to stand for 1, 4, 10, and 21 days before being leached with 5 l. of distilled water yielding 3 in. of drainage water for the surface exposed.

All nitrogen applied as nitrate and one-third of the nitrogen applied as ammonium sulfate or ammonium nitrate were leached. The leaching of the ammonium ion from ammonium phosphate was very low. Ammonium carbonate was retained very efficiently by the soil until nitrification began. Urea leached as much to the extent of 35 percent and 16 percent after 1- and 4-day incubation periods, respectively. Ammonium nitrogen was retained very efficiently by the soil until nitrification began. Then both ammonium and nitrate nitrogen leached. Very little difference was noted in the nitrogen content of the leachates from the untreated cultures and the cultures treated with the insoluble organic fertilizers.

A second series of cultures of four soil types were given sodium nitrate, ammonium sulfate, urea, castor pomace, and no treatment. All cultures were incubated for 4 days before they were leached with sufficient water to effect a quantity of drainage equivalent to 3 in. of water for the surface exposed. The nitrates leached almost completely except from Norfolk fine sandy loam,

which retained 27.8 percent in the soil. Of the ammonium nitrogen applied as ammonium sulfate, 40 percent leached from Norfolk sand, while insignificant amounts leached from the other soils. No urea was found in any of the leachates. The castor pomace treatment gave results very similar to those of the no-treatment cultures after 4 days. The leachates showed acidity greater than that of the soils. The pH value of the soil was increased by leaching. The most significant effect on the acidity of the soil was induced by urea, which materially raised the pH.

Effect of phosphates on nitrifying capacity of soils, (G. S. FRAPS and A. J. STERGES. (Tex. Expt. Sta.). (*Soil Sci.*, 47 (1939), No. 2, pp. 115-121).—Of 171 soil samples, 32 nitrified less than 60 percent of the ammonia-nitrogen added even though nitrifying organisms and calcium carbonate were added. Addition of phosphates increased the nitrifying capacity of most of these soils. Monocalcium phosphate alone increased the nitrification in 4 of 18 such soils. Monocalcium phosphate with calcium carbonate increased the nitrification percentage in 16 of the 18 soils over that attained with calcium carbonate alone. Dicalcium phosphate increased nitrification in 29 soils which did not completely nitrify when inoculating liquid and calcium carbonate were added. Nitrites were present in some of the cultures, but the number containing nitrites and the quantities of nitrite present were smaller when phosphates were added than when they were not added. The average order of decreasing effectiveness of phosphates in promoting nitrification in 14 soils was found to be as follows: Monopotassium phosphate, 20 percent superphosphate, dipotassium phosphate, monocalcium phosphate, tricalcium phosphate, dicalcium phosphate, disodium phosphate, rock phosphates, soft phosphate with colloidal clay.

There were differences in the quantities of the active phosphoric acid, acid-soluble lime, basicity, and pH values in the soils which responded to phosphates, but the prevailing characteristics seemed to be those of low active phosphate content and fair to high lime content and basicity.

The movement and fixation of superphosphate in soils, B. E. BEATER (*Soil Sci.*, 46 (1938), No. 6, pp. 453-466).—The movement and fixation of superphosphate under field conditions in two distinct soil types was ascertained by applying superphosphate as top dressing under irrigation, as top dressing without irrigation, in the drill, and buried. Total, citric-soluble, and water-soluble phosphoric acid were estimated.

Erosion of total phosphate from surface dressings was considerable, being greater in the heavier soil type. In both soil types this was very greatly reduced by watering. Movement of total phosphoric acid could not be treated appreciably below the first inch from the surface, even in the lighter soil. Occasional penetration appeared to take place in fissures. Loss from the buried superphosphate occurred in neither the heavier nor the light soil. No movement below or above was detected in the buried fertilizer.

It was further found that "the fixation by analytical process in a heavy soil type is so much greater than that in a light soil as, perhaps, to obscure the results obtained. As a result, the fixation with time in a light soil stands out more clearly than that in a heavy type, although a heavier fixation in the heavy type actually takes place. . . . Water-soluble phosphate is lost in considerable amounts in process of estimation in a heavy soil type and in appreciable amounts in a lighter type."

Watering tended to prolong somewhat the availability of phosphate. After 14 days virtually all the water-soluble phosphate had disappeared from the heavy soil, but at the end of a year some still remained in the light soil, the loss

being very gradual. In a heavy soil type the increase in water-soluble phosphate, due to applications of 800 lb. superphosphate per acre, was almost negligible, whether the dressing had been applied in the soil or on the surface.

Phosphorus fixation by horizons of various soil types in relation to dilute acid extractable iron and aluminum, D. S. ROMINE and W. H. METZGER. (Kans. State Col.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 2, pp. 99-108, figs. 3).—Extraction of "available" phosphorus by the Truog solution (E. S. R., 64, p. 312) reduced the capacity of the soil to absorb phosphorus. The percentage reduction in absorption after extraction of available phosphorus was highest in the relatively unleached soils. The percentage reduction in the A horizons was greater than in either the B or C horizons. In all horizons the reduction in "apparent absorptive capacity" (available phosphorus plus phosphorus absorbed by original soil) resulting from extraction of the soil by the Truog reagent varied with the general trend of the R_2O_5 extracted. The B and C horizons of rather heavily leached soils absorbed from two to five times as much phosphorus as did the B and C horizons of the relatively unleached soils. In all cases the B horizons showed greater absorption than the A horizons. In general, the lowest availability occurred in the B horizons. In the unleached profiles, high available phosphorus was associated with relatively high amounts of extractable R_2O_5 . Low availability was associated with low pH values.

Phosphate investigations in Montana, 1938, W. P. WILLIS, JR., and F. M. HARRINGTON (*Montana Sta. Bul.* 369 (1939), pp. 30, figs. 4).—In experiments on alfalfa, sugar beets, wheat, and forage grasses, increased yield was usually accompanied by increased phosphate content in the crop plants. Soils showing phosphate deficiency in the Winogradsky test mostly showed phosphate response in the field. Residual effects on alfalfa in the second and third years after phosphating were observed. The lower lands showed more response than did bench lands or higher lands. Phosphating gave less increase in the wheat crop than in those of alfalfa or beets. The phosphate content of the grasses was markedly increased by available phosphates. Through 3 yr. the alfalfa and beets showed little response to raw phosphate rock.

In experiments on potatoes the number of tubers set, the yield, and the grade were all improved by the use of phosphate fertilizers. In one instance in the 1938 tests scab was materially less where phosphate had been applied.

The nature, extent, and distribution of fertilizer residues in the soil of some old fertility plats, W. H. METZGER (Kans. Expt. Sta.). (*Soil Sci.*, 47 (1939), No. 1, pp. 15-26, fig. 1).—This paper reports findings with respect to fertilizers applied as top dressings for continuous alfalfa during 27 yr.

A large proportion of the easily soluble phosphorus which accumulated in the soil as a result of treatment with various phosphorus carriers was found in the surface 4 in. of soil. There appeared to be accumulated phosphorus to depths of from 2 to 3 ft., however, in plats treated with rock phosphate and manure and with lime and manure and to a lesser extent in the superphosphate plat. Potassium salts, with or without sodium nitrate, applied with superphosphate resulted in more complete utilization of the phosphorus by the plants than did superphosphate used alone. Accumulations of total phosphorus in the surface 4 in. of soil and in immediately succeeding depths amounted to from 3 to 191 percent of the native phosphorus of the soil. Lime appeared to have brought about the retention of more of the phosphorus applied in the form of manure than where manure was applied alone, and at the same time it aided phosphorus penetration. In general, phosphorus applied in manure was largely utilized by the plants and little accumulated. Where superphosphate was applied, alone or supplemented, 70 percent or more of the accumulated

phosphorus was fixed in difficultly soluble form. Rock phosphate was much less strongly fixed, and at depths of from 1 to 2 ft. the accumulated phosphorus was entirely soluble in dilute acid. Except in the surface 4 in. of soil, phosphorus residual from manure was very largely fixed in difficultly soluble form.

The data did not show definitely that residual phosphorus increased the base exchange capacity of the soil. Lime and manure treatment brought about an appreciable increase, however, and this increased exchange capacity disappeared when the soil was electrodyalized. Ultimate pH values were unaffected by the phosphorus treatments. The exchangeable sodium content of the soil was increased somewhat by a treatment involving NaNO_3 , but most of the accumulation was at depths of from 1.5 to 3 ft.

The potassium treatments, which were light, left only very small residues confined to the upper 9 in. of soil. Exchangeable potassium appeared to have been maintained or accumulated more effectively than did total potassium. Limited data indicated that where total potassium was increased, as a result of treatments, from 77 to 96 percent of the accumulated potassium was fixed in nonexchangeable form.

Fertilizing constituents of cotton burs or cotton bur ashes and their effect on crop yields, H. J. HARPER, H. A. DANIEL, and G. W. VOLK. (Okla. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 30 (1938), No. 10, pp. 827-832).—Three tons of burs applied at intervals of 3 yr. since 1926, either plowed or disked into the soil, have given as good returns as 6 tons on adjacent plats treated in a similar manner. The average seed cotton increase was 180 lb. per acre when the lightest application was plowed under and 166 lb. when disked into the soil. The highest average gain from the heaviest treatment was 170 lb. of seed cotton per acre. Ashes from equivalent amounts of burs produced only about one-half as great an increase in yield as the burs.

Cotton burs from 22 counties in Oklahoma contained an average of 8.73 percent ash, 1.04 nitrogen, 0.1 phosphorus, 0.65 calcium, 3.39 potassium, and 0.25 percent magnesium, calculated on a moisture-free basis. The average nutrient content of cotton bur ashes was found to be as follows: Phosphoric anhydride 2.68 percent, calcium oxide 10.41, potassium oxide 45.15, and magnesium oxide 4.76 percent.

Fertilizer placement for vegetable crops, H. H. ZIMMERLEY. (Va. Truck Expt. Sta.). (*Veg. Growers Assoc. Amer. Ann. Rpt.*, 1937, pp. 34-47).—Essentially similar material has been noted from other sources (E. S. R., 78, p. 166).

Commercial fertilizers, 1938, E. R. TOBEY (*Maine Sta. Off. Insp.* 169 (1938), pp. 59-89).—The analyses of the 1938 inspection here reported include ammonia, nitrate, and organic nitrogen; the usual phosphate and potassium data; and both water-soluble and total-magnesium content when a guaranty of the last-named element was made. Single-element fertilizer compounds and liming materials are also covered in this report.

Inspection of commercial fertilizers for 1938, T. O. SMITH and H. A. DAVIS (*New Hampshire Sta. Bul.* 311 (1938), pp. 14).—This report on the analyses for 1938 of 106 fertilizer materials deals with their composition and guaranty.

Fertilizer statistics for Texas, 1926-1938, G. S. FRAPS and T. L. OGIER (*Texas Sta. Bul.* 572 (1939), pp. 23, fig. 1).—This bulletin contains statistics of fertilizer sold in Texas from 1926 to 1938. The tonnage of various grades, the selling price of the various grades, and the relation between the selling price and valuations are shown, together with the approximate cost of nitrogen, phosphoric acid, and potash in cents per pound for the past 12 yr.

AGRICULTURAL BOTANY

[Papers on agricultural botany presented before the Botanical Society of America, Richmond, Virginia, December 28 to 30, 1938] (*Amer. Jour. Bot.*, 25 (1938), No. 10, Sup., pp. 2, 3, 4, 6, 7, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20).—Abstracts of the following are included: Cytological Effects of Colchicine Upon Division of the Generative Cell in Pollen Tubes of *Lilium*, by O. J. Eigsti; Nuclear Size in the Differentiating Spiral Elements of *Ricinus communis*, by F. M. Scott (Univ. Calif.); Influence of Auxones on Hypocotyledonary Bud Initiation in Flax, by G. K. K. Link and V. Eggers; Sublimax Prairie, by W. E. Loomis and A. L. McComb (Iowa State Col.); Rainfall Conduction by Trunks of Trees in a Tropical Rain Forest, by P. D. Voth; Growth Rings in Hemlocks, by G. S. Avery, Jr., H. B. Creighton, and C. W. Hock; Progress in the Color Photography of Plants, by P. L. Ricker (U. S. D. A.); Structure of the Cell Wall of the *Avena* Coleoptile During Growth, by T. Kerr and K. V. Thimann (U. S. D. A. et al.); Distribution and Development of Tobacco Roots, by L. J. Gier; New Research Methods for the Study of Economic Plants, by W. T. Swingle (U. S. D. A.); The Relation Between Cell Division, Cell Enlargement, and Growth Rate, by E. W. Sinnott; Effects of Heat on Yeast—I, Rate of Death of Cells Which Survive Moderate Treatment, by T. F. Anderson and B. M. Duggar (Univ. Wis.); Growth and Cell Structure in the First Internode and Coleoptile of *Avena* as Affected by Red, Green, Blue, and Violet Radiation, by G. S. Avery, Jr., P. R. Burkholder, and H. B. Creighton (Univ. Mo. et al.); Auxin Content of Embryos and Endosperms of Germinating Maize, and A Constant Temperature Constant Humidity Chamber to Obviate the Necessity of Expensive Control Rooms for Phytohormone Tests, both by G. S. Avery, Jr., H. B. Creighton, and C. W. Hock; Production of Growth-Promoting Substance by Bacteria Grown in Cultures Containing Single Amino Acids, and Growth Promoting Substance From Tryptophane and Vitamin C in Vitro, both by P. R. Burkholder (Univ. Mo.); The Respiration of Baker's Yeast in Various Concentrations of Dextrose and Cyanide, by B. Commoner; The Use of Nicotinic Acid in the Culture of Excised Plant Parts, by R. F. Dawson; Factors Causing Early Development and Vernalization, by H. G. du Buy (Univ. Md.); Response of *Adiantum cuneatum* to the Photoperiod, by J. K. Edwards; Fat Metabolism in the Soybean Seed, by H. C. Eyster; Heartwood—Its Formation and Characteristics, by E. Gerry (U. S. D. A.); The Cause of Natural Parthenocarpy, by F. G. Gustafson; Control of Bud Growth and Initiation of Roots at the Cut Surface of Potato Tubers by Treatment With Growth-Regulating Substances, by J. D. Guthrie; Identification of Applied Growth Substances, by A. E. Hitchcock and P. W. Zimmerman; New or Modified Chlorophylls of *Datura stramonium*, by O. L. Inman and A. F. Blakeslee; Effects of 3-Indole Acetic Acid on the Outgrowth of Roots From Isolated Portions of *Bryophyllum* Leaves, by S. Kaiser and H. G. Albaum; The Enlargement of the Cotton Boll, by T. Kerr (U. S. D. A.); Spectral Sensitivity of Spores and Sporidia of *Ustilago zae* to Monochromatic Ultra-Violet Light, by E. W. Landen (Univ. Mo.); Aphids, Auxones, Pseudogalls, and Galls, by G. K. K. Link and V. Eggers; Effect of Some Vitamins on Growth of *Lupinus albus* Seedlings, by D. I. Macht and M. L. Grumbel; Formation of Glucosides by Plant Tissue From Introduced Aglucons, by L. P. Miller; The Path of Fluorescein Movement in the Red Kidney Bean, *Phaseolus vulgaris* L., by E. M. Palmquist (Cornell Univ.); A Technique for the Cytological Study of Living Plant Cells, by H. S. Reed and E. T. Eltinge (Univ. Calif.); Tree Temperatures and Thermotaxy, by E. S. Reynolds; Quantum Efficiency of Photosynthesis in *Chloroclla*, by J. F. Stauffer (Univ. Wis.); Experiments on the Rooting of *Pisum* Cuttings,

by L. A. Thayer; The Vegetative Propagation of Difficult Plants, by K. V. Thimann and A. L. Delisle; The Relative Activities of Different Auxins, and A Modified Auxin Test of High Sensitivity, both by K. V. Thimann and C. L. Schneider; Oxygen Regulates the Dormancy of the Potato, by N. C. Thornton; The Relative Humidity of Stomatal Openings and Intercellular Spaces of Some Leaves, by H. F. Thut; Temperature Relations in the Germination of *Digitaria*, by E. H. and V. K. Toole (U. S. D. A.); Ultra-Violet Transmission by Pollen of *Zea mays*, by F. M. Uber (Univ. Mo.); Potentially Unlimited Growth of Excised Plant Callus in an Artificial Nutrient, by P. R. White; The Bound Water Content of Native Prairie Species in Relation to Environmental Conditions, by W. Whitman (N. Dak. Expt. Sta.); The Factors Influencing the Number of Stomata, by L. E. Yocum; The Relation of Anatomy and Cytology to the Classification of the Leguminosae, by H. A. Senn; The Anatomy and Development of the Spider Lily Seed, by M. Whitehead and C. A. Brown (La. State Univ.); and Geographic Relations in the Genus *Phlox*, by E. T. Wherry.

Titles and abstracts of papers to be presented before the fifteenth annual meeting of the American Society of Plant Physiologists, December 28-30, 1938, Richmond, Virginia (*Richmond: Amer. Soc. Plant Physiol., 1938, pp. 20*).—Abstracts of the following are included: The Role of Magnesium in *Chlorella* Photosynthesis, by S. R. Kennedy, Jr. (Cornell Univ.); Chlorophyll—Its Estimation, by F. M. Schertz; The Influence of Cooling the Atmosphere on the Rate of Apparent Photosynthesis of Apple Trees of Bearing Age, by A. J. Heinicke (Cornell Univ.); CO_2 Leakage Through Glass as an Explanation of Gain in Weight by Flasks Containing Plant Photosynthetically Active, by E. A. Spessard; New Evidence of the Formation of a Carbon Dioxide-Combining Intermediate During Photosynthesis, by E. D. McAlister; Light-Mass Absorption During Photosynthesis, by E. A. Spessard; Chlorophyll—Its Function, by F. M. Schertz; Some Effects of Storage Temperatures and Atmospheric Conditions Upon Potato Tubers, by J. C. Dodge and E. L. Overholser; Response of Germinating Seed of Shortleaf Pine to Different Hydrogen-Ion and Calcium Concentrations, by A. G. Chapman; The Relation of Freezable and Unfreezable Water to Oxygen Respiration in Some Seeds, by H. G. Shirk and C. O. Appleman (Md. Expt. Sta.); The Daily Rate of Photosynthesis of Two Varieties of Tomato During Their Growing Season, 1938, by J. A. Campbell and N. F. Childers (Ohio); Absorption of Radiant Energy by Leaves, by W. E. Loomis and P. H. Carr (Iowa State Univ.); Preliminary Report on Plant Responses to Fluorescent Light, by C. F. Moreland and L. H. Flint (La. State Univ.); Effects of Temperature and Sunlight on the Rate of Elongation of Stems of Maize and *Gnaphalium*, by A. G. McCalla, J. R. Weir, and K. W. Neatby; Anatomical Changes Preceding Blossom Formation, by B. E. Struckmeyer and R. H. Roberts (Univ. Wis.); The Relation Between the Structure and Function of the Phloem, by A. S. Crafts; Translocation of Materials in a Deeply Girdled Maple, by G. P. Burns (Univ. Vt.); The Effects of Drops of Water on Leaf Temperatures, by P. J. Kramer; The Effect of Certain Variables Upon the Freezing Point Depression of Plant Tissues, by P. E. Ussery (Va.); Relation of Root Reserves to Control of European Bindweed (*Convolvulus arvensis* L.), by A. L. Bakke, W. G. Gaessler, and W. E. Loomis (Iowa State Col.); and A Study of the Chemical Composition of *Suckleya suckleyana* (a cyanogenetic plant in Colorado), by C. G. Barr, H. W. Reuszer, and F. Thorp, Jr. (Colo.).

Proceedings of local branches of the Society of American Bacteriologists (*Jour. Bact.*, 37 (1939), No. 2, pp. 223, 224, 227, 230, 233, 234, 235).—Abstracts of the following papers are included: Further Experiments in the Disinfection of Seeds, by A. W. Hofer and H. C. Hamilton (N. Y. State Expt. Sta.); Some Effects of Low Velocity Electrons on Microorganisms, by C. P. Haskins; A Simplified Apparatus for the Preservation of Bacterial Cultures in the Dried State, by F. J. Grabill and M. L. Cooper; Studies of Cacao Fermentation, by S. Hoynak, T. S. Polansky, and R. W. Stone (Pa. State Col.); and A Study of the Epidemiology of Tobacco Wildfire, by H. D. McAuliffe, M. A. Farrell, D. E. Haley, and J. J. Reid, and A Cultural and Serological Study of *Phytomonas tabaca* and Certain Related Forms, by J. J. Reid, J. Naghski, R. G. Harris, and H. D. McAuliffe (both Pa. Expt. Sta.).

Growth factor requirements of the root nodule bacteria, P. M. WEST and P. W. WILSON. (Univ. Ws.). (*Jour. Bact.*, 37 (1939), No. 2, pp. 161-185, pls. 3, figs. 7).—*Rhizobium trifolii* synthesized all its essential organic substances from the simple ingredients of a properly reduced carbohydrate-mineral salts medium. Continuous transfer in a synthetic medium is said to depend on a factor synthesized by the growing organism which is ordinarily transferred in sufficient quantity in the inoculum to stimulate growth initiation. This factor was separated from *Rhizobium* cultures by ultrafiltration and was readily destroyed by heat. Either thiamin or flavin alone proved capable of replacing to some extent the stimulative factor synthesized by *R. trifolii*, but certain combinations of both vitamins were more active than either one alone. The organism synthesized appreciable quantities of both vitamin B₁ and riboflavin, and these vitamins were present in culture autolysates or filtrates as complexes which

were readily destroyed by heat, with resultant decreased activity. Further evidence is presented to indicate that the activity of the metabolic products of *R. trifolii* in stimulating growth initiation of the same organism is due, at least in part, to the presence of thiamin and flavin.

Host plant specificity among the *Medicago* in association with root-nodule bacteria, J. C. BURTON and P. W. WILSON. (Univ. Wis.). (*Soil Sci.*, 47 (1939), No. 4, pp. 293-303, pl. 1, figs. 2).—Three *M. sativa* varieties (Ladak, Hairy Peruvian, and Grimm) were tested for nitrogen-fixing ability in association with nine strains of *Rhizobium meliloti* under differing environmental conditions. Although there was definite evidence of host specificity, its occurrence tended to be erratic. The host-bacterial relationship was apparently affected by other factors (e. g., environmental conditions) which obscured the specific host influence. Five *Medicago* species were also tested for nitrogen-fixing power in association with the same nine bacterial strains, and unequivocal host specificity was established among these species. On *M. sativa*, *M. lupulina*, and *M. minima* all bacterial strains were very efficient with one possible exception (strain 105 on *M. sativa*). In contrast, strain 105 only proved capable of fixing nitrogen in association with *M. arabica* and *M. hispida*.

Note on the successive dilution method for estimating bacterial populations, R. D. GORDON and C. E. ZOBELL (*Zentbl. Bakt. [etc.]*, 2 Abt., 99 (1938), No. 14-17, pp. 318-320, figs. 2).—Experimental data from the literature are arranged graphically so as to corroborate the conclusion, arrived at on theoretical grounds by the senior author (E. S. R., 80, p. 20), that modal estimates of bacterial densities based on successive dilution procedure are unsatisfactory for bacteriological purposes. The geometrical mean is proposed as the correct (simple) estimate, for which formulas have been developed (loc. cit.).

Homothallism in *Pythium*, T. C. VANTERPOOL (*Mycologia*, 31 (1939), No. 2, pp. 124-127).—The complex condition in the thallism of certain species of *Pythophthora* and *Peronospora* is pointed out, strict homothallism is shown to exist in the five species of *Pythium* studied, and a method of obtaining single zoospore cultures of *Pythium* is detailed.

Embryo-sac development in *Plumbagella*, J. W. BOYES. (Univ. Wis.). (*Natl. Acad. Sci. Proc.*, 25 (1939), No. 3, pp. 141-145, figs. 9).—A morphological and cytological study.

Some Venezuelan fungi [trans. title], R. A. TOZO (*Jour. Agr. Univ. Puerto Rico [Col. Sta.]*, 22 (1938), No. 4, pp. 449-454, pl. 1).—Various additions have been made since the publication in 1934 by Chardon and Thoro (E. S. R., 72, p. 460). "The present paper represents an attempt to identify some of the specimens which were collected in the course of the several trips to Venezuela," and includes *Schiffnerula paraparensis* n. sp. and *Kerniomyces costi* n. g. and sp.

A few new Zoöpagaceae destructive to large soil rhizopods, C. DRECHSLER. (U. S. D. A.). (*Mycologia*, 31 (1939), No. 2, pp. 128-153, figs. 7).—Four species of *Cochlonema* (two new) and *Acaulopage marantica* n. sp. are described and discussed. It is suggested that the feeding operations of this group of fungi may have an important relation to the pronounced fluctuations in populations of soil protozoa when determinations of their numbers are made from day to day.

The validity and morphology of two *Trybliidiella* species, R. K. VOORHEES. (Fla. Expt. Sta.). (*Mycologia*, 31 (1939), No. 2, pp. 113-123, figs. 4).—It is concluded that according to present ideas of classification *T. rufula* and *T. fusca* can be separated into two distinct species by the morphological characters of the ascocarps. There are 11 literature references.

Dissection and preparation of whole mounts of endosperm from the seeds of *Grevillea* (Proteaceae), S. B. KATSIK (*Stain Technol.*, 14 (1939), No. 2, pp. 43-46, figs. 3).—It is sometimes very desirable to supplement the examination of serially cut microtome sections by dissection and study of whole mounts of objects. The present note is intended to point out another instance where such study is needed and to outline a successful procedure.

A Nile blue culture medium for lipolytic microorganisms, G. M. EISENBERG (*Stain Technol.*, 14 (1939), No. 2, pp. 63-67).—The procedure outlined for enumerating lipolytic microorganisms makes use of Nile blue sulfate as a specific indicator for detecting changes in neutral fats. The medium is said to be equally efficient for either pour or streak plates.

Staining solutions included in the National Formulary, H. J. CONN (*Stain Technol.*, 14 (1939), No. 2, pp. 41, 42).

Stains recently certified (*Stain Technol.*, 14 (1939), No. 2, p. 42).—This is an annotated list.

A new sharpening back and procedure of sharpening for microtome knives, W. EVENDEN and C. E. SCHUSTER. (U. S. D. A.). (*Stain Technol.*, 14 (1939), No. 2, pp. 69-71, fig. 1).—The advantages claimed for the new detachable knife sharpening back here described and illustrated, are that it is exactly replaceable in one position and is immovable in use and has long-wearing qualities.

The preparation of hardened embedding paraffins having low melting points, H. C. WATERMAN (*Stain Technol.*, 14 (1939), No. 2, pp. 55-62).—"Technical 'stearic acid' hardens paraffins melting at 52° C. and above, and at the same time lowers the melting point. Spermaceti wax further lowers the melting point of such a mixture without much effect on the hardness. With these two substances, and one of the anticrystallizing adjuvants already found satisfactory, embedding media yielding thin sections at room temperature and having melting point below 52° can easily be prepared. A general method is given, specific formulas are stated, and the behavior at various temperatures of typical embedding media of this kind is described."

Micellar concept [trans. title], A. FREY-WYSSLING (*Chron. Bot.*, 5 (1939), No. 1, pp. 9, 10, fig. 1).—A presentation of the modified micellar theory of Nägeli proposed by the author which looks upon the micellae present in organized biological substances as bound together in a netlike structure by interconnecting molecular strands in a manner which conditions the infiltrability, stainability, and permeability, as well as the mechanical and optical properties of such substances. This conception is held to apply probably to the submicroscopic structure of protoplasm and its derivatives such as starch, cellulose, chitin, silk fibroin, keratin, collagen, muscle myosin, etc.

The microfibrillar and microcapillary structure of the cell wall, I. W. BAILEY (*Bul. Torrey Bot. Club.* 66 (1939), No. 4, pp. 201-213, figs. 11).—This is a critical, analytical review (14 references) of studies of cells of various tissues in a wide range of both angiosperms and gymnosperms.

Role of synaeresis in the mechanism of cell freezing [trans. title], P. BECQUET (*Chron. Bot.*, 5 (1939), No. 1, pp. 10, 11).—A discussion of the probable relation of this well-known phenomenon of physical chemistry to the behavior of the cytoplasm and nucleus of living plant cells exposed to different degrees of low temperature. Tested at -190° to -25° C., plant tissues were never killed by plasmolysis, but the cold appeared to induce synaeresis in the colloidal systems of the cytoplasm, nucleus, and cell sap terminating in the formation, during death, of an irreversible conglutium composed of large colloid protoid micellae. The exudation of water which occurs on thawing is considered as

arising from the water of synaeresis, which easily escapes after the granular coagulation which destroys the semipermeability of the plasma membranes.

The morphology and embryogeny of *Sequoia gigantea*, J. T. BUCHHOLZ. (Univ. Ill.). (*Amer. Jour. Bot.*, 26 (1939), No. 2, pp. 93-101, figs. 31).—A study of the morphological and cytological details of embryo development is discussed and illustrated.

The fate of the indigenous, A. N. WILCOX. (Minn. Expt. Sta.). (*Minn. Acad. Sci. Proc.*, 5 (1937), pp. 15-23).—The author calls attention to some of the possibilities of a long-time, coordinated study from the ecological viewpoint of typical indigenous floras and faunas, describes an example of how such a study is being successfully conducted in England, and points out the exceptional opportunity in Minnesota. The need of preserving from further disturbance or extinction of relatively undisturbed natural areas for scientific observation is emphasized.

Some features of the vegetation of the Columbia River gorge with special reference to asymmetry in forest trees, D. B. LAWRENCE. (Univ. Minn.). (*Ecol. Monog.*, 9 (1939), No. 2, pp. 217-257, figs. 10).—The author discusses the physical and general vegetational features of the gorge, the flood tolerance of living firs and pines above the Cascade rapids, and asymmetric crowns and their relation to wind and weather in the gorge (the asymmetric crowns, weather conditions of the gorge as related to fir crowns, and crown asymmetry in general and its relations to wind direction, velocity, and duration). The gorge appears to have acted as an east-west corridor for, and as a north-south barrier to, plant migration.

Autonomic cycle of rate of exudation of plants, K. A. GROSSENBACHER. (Univ. Calif.). (*Amer. Jour. Bot.*, 26 (1939), No. 2, pp. 107-109, figs. 5).—A definite autonomic cycle of exudation from cut surfaces of stems of *Helianthus* cut off near the soil surface was found.

The role of potassium in plants.—I, Effect of varying amounts of potassium on nitrogenous, carbohydrate, and mineral metabolism in the tomato plant, M. E. WALL. (N. J. Expt. Stas.). (*Soil Sci.*, 47 (1939), No. 2, pp. 143-161, figs. 2).—Potassium deficiency symptoms are discussed, and evidence is presented that environal conditions in relation to internal metabolic changes due to K deficiency are primarily responsible for the different deficiency symptoms that have been noted. Deficiency in K appears to curtail protein synthesis, and this seems to occur in the stage amino acid-protein after amino acids have been formed. Accumulation of nitrates and carbohydrates is explained on a partial mass action effect. The final decrease in carbohydrates in K-deficient plants is ascribed to the effects of a decrease in assimilation and an increase in respiration. Plants deficient in K showed an increase in the absorption of other ions, particularly phosphate. "Preliminary evidence is given of a low concentration of potassium which is not only an optimum supply but is also close to a minimum supply for tomatoes in sand culture under the experimental conditions. The possible bearing of the antagonism of calcium to potassium in relation to carbohydrate assimilation and growth is discussed. There are 29 references.

Base content of corn plants as influenced by pH of substrate and form of nitrogen supply, C. H. WADLEIGH and J. W. SHIVE. (N. J. Expt. Stas.). (*Soil Sci.*, 47 (1939), No. 4, pp. 273-283).—In corn plants grown in two types of nutrient solutions, each adjusted to six different pH values between 3 and 8, the total base content of all was relatively high as compared with the usual value for soil-grown plants. There was a direct correlation between high K content and the pH of the expressed sap. Plants from the solution containing nitrate and ammonium N in approximately equal proportions showed considerably lower

total base content and lower pH of the expressed sap than plants from the solution containing nitrate N only. It appears that absorption of the ammonium ion lowers the absorption rate of the other cations. Its presence had the most depressing effect on the absorption of Ca and the least on that of Mg. It was indicated that high K absorption has a depressing effect on that of Ca and Mg. The presence or absence of the ammonium ion had a much more marked effect on absorption and accumulation of bases than had the variation in pH levels. The results appear to indicate that the pH values of solution films adjacent to roots in contact with solutions containing both nitrate and ammonium N were considerably lower than those of corresponding films on roots in contact with solutions containing nitrate N only, regardless of the pH levels of the body of the solutions. It is suggested that this is partially responsible for the difference in base content in the two series of plants studied.

The necessity of some minor elements in the economy of plants and animals. J. S. MCHARGUE. (Ky. Expt. Sta.). (*Ky. Acad. Sci. Trans.*, 7 (1935-37), pp. 38-52, figs. 12).—In his "president's address," the author claims that the detail and careful precision required in the procedures described "possess some novel ideas, which are of fundamental importance in ascertaining the essential nature of the minor elements in the economy of both plants and animals; furthermore, that the very striking results which have been obtained on the growth of fungi, yeast, forage crops, and vegetables, by a close observance of the procedures described, contribute to a better understanding of the function of a number of the minor elements in the art and science of agriculture."

Bibliography of references to the literature on the minor elements and their relation to plant and animal nutrition, compiled by L. G. WILLIS (*New York: Chilean Nitrate Ed. Bur., Inc., 1939. 3. ed., pp. [3]+488*).—This edition of the bibliography contains 4,628 abstracts and references, which is 1,862 more than the second edition (E. S. R., 77, p. 590).

Physiology of ethylene production, use, and reactions in plants, R. C. NELSON. (Univ. Minn.). (*Minn. Acad. Sci. Proc.*, 6 (1938), pp. 37-41, figs. 2).—This is a review, with bibliographic footnotes, leading to the conclusion that "in any case, it seems that ethylene is concerned with the respiratory processes, being produced by them and perhaps acting as a regulator of them. More than this cannot positively be said at the present."

The metabolism of amides in green plants.—II, The amides of the rhubarb leaf, H. B. VICKERY, G. W. PUCHER, C. S. LEAVENWORTH, and A. J. WAKEMAN. (Conn. [New Haven] Expt. Sta. et al.). (*Jour. Biol. Chem.*, 125 (1938), No. 2, pp. 527-538).—Continuing this series (E. S. R., 78, p. 465), rhubarb leaves were found to be far more acid than those of tobacco, and very considerable concentrations of ammonium ion may be normally present. An amide-synthesizing mechanism is present which responds when concentrations of the latter rise as a result of protein decomposition during culture of detached leaves. Glutamine was synthesized both in light and in darkness. Though the ability to produce glutamine from ammonia and some unknown carbon compound is certain, it is deemed quite possible that a substantial part of the newly formed glutamine may be directly derived from the protein. Theories of the mechanism and effects of glutamine synthesis are discussed. The general mechanism for ammonia production in plant tissues from deamination of amino acids of protein origin is considered applicable to rhubarb, and an approximately quantitative relationship in the nature of a balance sheet between the α -amino nitrogen and the products of its transformations can be drawn up. However, excess ammonia is said to be invariably found which indicates that minor amounts of nitrogen in form other than α -amino nitrogen may become involved in the

oxidation reactions. No positive evidence of the nature of the glutamine precursor was found. Synthesis occurred in parallel tests almost equally well in light and darkness, and thus does not depend on the presence of the immediate products of photosynthesis as in tobacco. Culture on glucose solution in the dark gave no marked increase in glutamine production, though there was evidence that the glucose entered the tissues and that ample ammonia was present. Glucose is thus probably neither the direct nor the indirect precursor of glutamine in rhubarb.

Physiological youth as an important factor in adaptive enzyme formation, C. P. HEGARTY. (Cornell Univ.). (*Jour. Bact.*, 37 (1939), No. 2, pp. 145-152, figs. 2).—Using *Streptococcus lactis* as test organism, the most rapid adaptation to new sugars occurred with cells from cultures just coming out of the lag phase, during the period of physiological youth. During the logarithmic phase, adaptability decreased rapidly and continuously. During aging of a culture, the ease of adaptation and the rate of loss of adaptability varied greatly with each sugar.

Cation interchange between plant roots and soil colloids, H. JENNY and R. OVERSTREET. (Univ. Calif.). (*Soil Sci.*, 47 (1939), No. 4, pp. 257-272, figs. 4).—"Low salt barley roots tenaciously retain their potassium against distilled water over a period of at least 10 hr. Salt solutions of moderate concentrations do not appreciably influence the potassium level of the roots investigated. Dilute clay suspensions carrying adsorbed Na, NH₄, or H ions pull out potassium from normal low salt roots. During the brief interval of 10 hr., the potassium level of the root may be reduced 15 to 90 percent, depending on clay concentration, particle size, and the nature of the adsorbed cation. Ca-bentonites, in the concentrations used, do not greatly affect the potassium status of the roots. If the roots and the clay particles are separated by a semipermeable membrane, the aforementioned effects are not observed. The effects are also absent if positive iron hydroxide sols are substituted for the negative clay sols. It is concluded that these experiments reveal the existence of a contact phenomenon between plant roots and clay particles. A theory of contact exchange is proposed according to which cations may transfer from clay to root and vice versa without entering the soil solution."

The effect of the composition of the medium upon the growth of yeast in the presence of bios preparations.—II, The response of several strains of *Saccharomyces cerevisiae*, J. B. LESH, L. A. UNDERKOFER, and E. I. FULMER. (Iowa State Col.). (*Jour. Amer. Chem. Soc.*, 60 (1938), No. 10, pp. 2505-2507).—Data were previously presented¹ indicating that for the one strain of yeast used the presence of MgSO₄ markedly increased its growth in the presence of bios II or a mixture of bios II and bios I (*D*-inositol). The present paper reports the effects of bios II, bios I, and MgSO₄ alone and in combinations on the growth of 13 strains of *S. cerevisiae*. On the basis of the marked differences in response to the different media these strains were separated into three distinct groups.

Effect of phytohormone dusts on growth and yield of winter wheat varieties, G. P. McROSTIE, J. W. HOPKINS, and N. H. GRACE (*Canad. Jour. Res.*, 16 (1938), No. 12, Sect. C, pp. 510-515).—Indolylacetic and naphthylacetic acids in various concentrations were applied to 10 varieties of winter wheat before planting in a replicated field test, half of each plot receiving seed treated with Ceresan and hormone and the other half with Ceresan only. Some differences were visually apparent between the plots with and without hormone, and there

¹ *Jour. Amer. Chem. Soc.*, 58 (1936), No. 8, pp. 1356-1358.

were also statistically significant increases in straw production, and in yield and weight per bushel of the grain. However, the effects on grain yield were complicated by the differential response of varieties to the same treatment, at the higher dosages there being some depressions in yield. Both chemicals tended to reduce slightly the average nitrogen content of the grain. As a whole, the results appear to demonstrate the physiological activity of both hormones when applied in this way.

Potentially unlimited growth of excised plant callus in an artificial nutrient, P. R. WHITE (*Amer. Jour. Bot.*, 26 (1939), No. 2, pp. 59-64, figs. 13).—This growth was obtained on sterile 0.5 percent agar with a Uspenski solution, 2 percent sucrose and 0.01 percent of an extract of dried brewers' yeast. Tobacco, tomato, and beet tissues are reported to have been propagated in a similar manner to the *Nicotiana glauca* × *N. langsdorffii* stele tissue used in the experiments here described (E. S. R., 72, p. 185).

Growth of excised tomato roots in a synthetic solution, W. J. ROBBINS and M. B. SCHMIDT (*Bul. Torrey Bot. Club*, 66 (1939), No. 4, pp. 193-200, figs. 2).—In continuation of studies of excised tomato roots (E. S. R., 80, p. 26), one of the interesting but unexpected observations from the data here presented was that growth in the solutions supplemented with thiazole was generally superior to that in solutions supplemented with thiamin. With a considerable excess of thiamin, as occurred in the solutions in these tests, possibly sufficient pyrimidine was present to be injurious. The results led to the conclusion that amino acids are not essential for growth of these excised roots, as the sole source of nitrogen was in the form of nitrates. Although unlimited growth of this strain of tomato roots appeared possible in a solution of minerals and sugar, supplemented either with thiamin or thiazole, there is the possibility that the cane sugar used, in spite of its high purity, contained traces of another growth substance. It is not to be concluded from the results presented that excised roots of other kinds of plants must be supplied with thiamin or thiazole and vitamin B₆ for successful growth in liquid cultures, but it is necessary to understand the requirements of one root in order that the results may be intelligently applied to others.

Effect of some synthetic growth substances on root development of transplanted trees, P. E. TILFORD. (Ohio Expt. Sta.). (*Natl. Shade Tree Conf. Proc.*, 14 (1938), pp. 51-59, figs. 2).—Treatments at time of transplanting with some synthetic substances (indolebutyric, indoleacetic, indolepropionic, and phenylacetic acids) stimulated new root development on certain kinds of trees, the first named proving most effective of the four. Although no very practical method of using this material effectively on large trees can as yet be suggested, it is hoped that such can be developed.

Some experiments on bud growth, F. W. WENT (*Amer. Jour. Bot.*, 26 (1939), No. 2, pp. 109-117, figs. 5).—In tests with etiolated pea shoots the increasing inhibition with increase of distance between inhibited lateral bud and inhibiting agent was confirmed with indoleacetic acid applied at different distances from the bud, and the inhibiting effects of some nonauxins and substances with low growth activity are described. The results indicated that indoleacetic and γ phenylbutyric acids cause an accumulation of bud growth factors just below their point of application and that they do not inhibit growth by themselves. It is claimed that the inhibition is a secondary effect of the applied auxin. Some cases of inhibition of the apical bud by lateral buds are also described, and it is shown that bud inhibition can be induced in roots which regenerate buds on their basal cut surfaces in much the same way as in stems.

Cytogenetic results with colchicine, M. L. RUTTLE and B. R. NEBEL. (N. Y. State Expt. Sta.). (*Biol. Zentbl.*, 59 (1939), No. 1-2, pp. 79-87, figs. 3).—This is a review and progress report presenting data illustrative of the present status of a breeding program carried out by the senior author to demonstrate that colchicine is practically important to plant breeders willing to use cytogenetic methods. There are 14 literature references.

Observations on the immediate effects of colchicine, J. G. O'MARA (U. S. D. A. and Mo. Expt. Sta.). (*Jour. Heredity*, 30 (1939), No. 2, pp. 35-37, pl. 1).—"Observations on the effects of colchicine treatments for different periods and concentrations are recorded. The hypertrophy usually associated with treatment was found not to involve the meristem but the region of elongation. The colchicine-affected chromosomes are more accurately measurable than ordinary somatic chromosomes—this may indicate that the drug can be profitably used in studies of chromosome morphology in somatic tissues."

The newest fad, colchicine, and its origin, S. J. WELLENSEK (*Chron. Bot.* 5 (1939), No. 1, pp. 15-17).—A brief digest of the development of knowledge about the properties and effects of colchicine and its use to induce polyploidy.

Thiamin and plant growth, W. J. ROBBINS (*Science*, 89 (1939), No. 2310, pp. 303-307).—Studies by the author and his associates lead him to conclude that growth substances are important for plants as well as for animals, and that one of the most important for plants is thiamin, all or almost all of them apparently requiring it. It was demonstrated that some of the fungi studied which required no external supply of thiamin synthesized it, and it is deemed justifiable to assume that the others in this group also have the same power. The green plant is thus not the sole source of this vitamin. Depending on the organism concerned, thiamin may be considered a hormone, a vitamin, or something which is neither. The author therefore for the present prefers the term "growth substance" for any specific organic substance needed in small amounts for normal development of a living organism. Thiamin plays a significant role in carbohydrate metabolism and probably also in other metabolic processes. At least one of its functions is apparently to serve as a precursor of a part of an enzyme system involved in respiration, but probably this is not its sole function. It is believed that it has a multiple function as a coenzyme in nature. It is suggested that *Phycomyces* might be used advantageously in determining more completely the changes occurring in the intermediary metabolism of carbohydrates and in the quantitative determination of thiamin. Studies of this fungus, as well as of tomato and pea roots and staphylococci, have indicated thiamin to be quite specific, and this specificity is doubtless associated in part with its function as a precursor of a part of an enzyme system. Observations on growth in mixed cultures have proved most suggestive from the standpoints of parasitism and symbiosis, and attention is called to the promise in the plant-thiamin relationship of elucidating important questions in general physiology through the study of more easily controlled material than the higher animal. However, the point is stressed that thiamin is not the only growth substance concerned in plant development, and the functions of several others are briefly noted. Finally, it is emphasized that the physiological mechanisms of fundamental processes are much the same in all living organisms, although details differ.

A comparison of two quantitative Avena techniques in the determination of 3-indole acetic acid, R. H. GOODWIN (*Amer. Jour. Bot.*, 26 (1939), No. 2, pp. 74-78, fig. 1).—The method of Went with water-cultured and that of Boysen Jensen with soil-cultured plants each has certain advantages, as tested by the author. In a laboratory with no facilities for exact control of humidity in the

constant-temperature dark room, the second method may be most simply, accurately, and expeditiously used. In a completely air-conditioned dark room, however, the Went method is said to be more speedily executed and more readily standardized and modified. The relative accuracy of the two methods under such conditions was not investigated.

Control of crop nutrition by the method of foliar diagnosis, W. THOMAS and W. B. MACK (*Pennsylvania Sta. Bul.* 378 (1939), pp. 33, figs. 7).—The experimental foundation on which the foliar diagnosis method is based is outlined, certain concepts inherent in it are described, and the method is evaluated in relation to other procedures for soil and plant testing. Results of the use of this method are presented with corn on 13 differently fertilized field plats, and the interpretation of the data is shown by two methods of graphic analysis. The effects of the various fertilizers on the nutrition of the plants of each plat as indicated by differences in the intensities and compositions of the NPK units with advancing age of the leaf are compared. The relative effects of the different fertilizers on yields are the resultant of factors acting during growth, and are readily shown by a magnitude representing the mean values of the intensities of the NPK units, respectively, during the growth cycle. Applications of the method to the determination of suitable experimental sites for field plats, to the selection of a properly balanced fertilizer, to the diagnosis of pathological conditions associated with nutritional disturbances, and to plant breeding programs are described.

Plant injection, D. AKENHEAD (*Chron. Bot.*, 5 (1939), No. 1, pp. 31, 32).—A review of the contribution by Roach (*E. S. R.*, 80, p. 496), with special reference to rapid diagnosis of mineral deficiencies.

Behavior of sugarcane to length of day, G. B. SARTORIUS (U. S. D. A.). (*Internatl. Soc. Sugar Cane Technol. Cong. [Baton Rouge, La.] Rpts.*, 6 (1938), pp. 59, 60).—An abstract.

GENETICS

Abstracts of papers presented at the 1938 meetings of the Genetics Society of America (*Genetics*, 24 (1939), No. 1, pp. 65, 66, 77, 84, 85, 86, 95, 102, 103, 109, 110).—The following papers of botanical interest are included: Sectorial Chimeras, Chromosome Deficiencies and Doubling of Chromosome Number in *Datura stramonium* Induced by Colchicine Treatment, by A. D. Bergner, A. G. Avery, and A. F. Blakeslee; Characteristics of Induced Polyploids in Different Species of Angiosperms, by A. F. Blakeslee, H. E. Warmke, and A. G. Avery; Growth Changes Associated With Chromosome Breakage and Reattachment, by D. F. Jones (Conn. [New Haven] Expt. Sta.); The Effect of Colchicine-Induced Polyploidy on Fruit Shape in Cucurbits, by E. W. Sinnott, A. F. Blakeslee, and H. E. Warmke; Induction of Polyploidy in *Nicotiana* Species and Species Hybrids by Treatment With Colchicine, by H. H. Smith (U. S. D. A.); Induction of Diploids From Haploids by Colchicine Treatment, by A. F. Blakeslee and A. G. Avery; Physiological Factors Involved in Differentiation of Male and Female Parts of the Angiosperm Flower, by W. F. Loehwing; and Induction of Tetraploidy in *Nicotiana glauca* and in the Sterile Hybrid *N. tabacum* × *N. glutinosa* by Colchicine Treatment, by H. E. Warmke and A. F. Blakeslee.

Genetics in the U. S. S. R., N. I. VAVILOV (*Chron. Bot.*, 5 (1939), No. 1, pp. 14, 15).—A survey of the chief contributions presented at the February 1938 Moskva conference on interspecific and intergeneric hybridization and of the November 1938 Moskva conference on the use of physical and chemical methods of obtaining polyploids and amphidiploids.

Relationships in the genus *Gossypium* as indicated by cytological data. J. M. WEBBER. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 4, pp. 237-261).—The meiotic chromosome conjugation is reported of F_1 of 23 new interspecific hybrids, including 12 different types of hybrids; F_2 of certain 13- \times 13-chromosome combinations; and F_1 and F_2 of certain 13- \times 26-chromosome combinations. The conjugation observed, in conjunction with that previously reported, supports the grouping of the species as follows: The Australian species, *G. sturtii*; Asiatic species; wild American species; and cultivated American species. Relationships of species within and between these groups are discussed. Evidence for and against the various hypotheses of the origin of 13-chromosome species and of purely American origin of cultivated American cottons is given, and cytogenetic literature bearing critically on the relationships of species in *Gossypium* is reviewed and summarized in table form. See also an earlier note (E. S. R., 77, p. 34).

Cytogenetic observations in *Lactuca*. T. W. WHITAKER and I. C. JAGGER. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 4, pp. 297-306, figs. 3).—The following species of *Lactuca* were studied cytologically and reciprocal crosses among them attempted: *L. sativa*, *L. scariola*, *L. chondrillaeflora*, *L. perennis*, *L. tartarica*, *L. cretica*, *L. bourgaei*, *L. graminifolia*, and *L. canadensis*. Among the eight- and nine-chromosome species there were marked differences in the chromosome ideograms. The greatest degree of differentiation in chromosome morphology was observed in *L. sativa*. Normal pollen varied from 80 to 85 percent in some species to 90 to 95 percent in others. All except *L. perennis* were self-fertile. Fertile hybrids were obtained only between *L. sativa* \times *L. scariola* and *L. canadensis* \times *L. graminifolia*. No cytological irregularities were observed in the F_1 or F_2 . Irregularities during meiosis apparently reduced pollen fertility to from 80 to 85 percent in *L. bourgaei*, an eight-chromosome species.

Artificial induction of polyploidy in alfalfa. D. C. COOPER. (Wis. Expt. Sta.). (*Amer. Jour. Bot.*, 26 (1939), No. 2, pp. 65-67, figs. 2).—Among racemes of tripped flowers of alfalfa (*Medicago sativa*) subjected to heat treatment early in proembryo development, one tetraploid individual ($2n=64$) was obtained from a population treated at 42° C. at 47-48 hr. after pollination. The tetraploid plant is described as similar to diploids in general habit, but possessed of somewhat stouter stems and larger leaves and flowers. The stomata, epidermal cells, and pollen grains were appreciably larger than in the diploid. The quadrivalents present at diakinesis in the microsporogenesis of the tetraploid varied from three to six. Lagging chromosomes were present on both the heterotypic and homeotypic spindles. The induced tetraploid was highly sterile. Three offspring are reported from seeds resulting from self-pollination, all of which are tetraploid.

Heritable variations conditioned by euploid chromosome alterations. D. KOSROFF (*Chron. Bot.*, 5 (1939), No. 1, pp. 17-19).—Reasons are given why it appears desirable for investigators who attempt to produce polyploids for practical purposes (especially with colchicine and acenaphthene) to restrict their work chiefly to plants with small chromosome numbers and with short chromosomes.

Amphidiploids in the Triticinae induced by colchicine. E. R. SEARS. (U. S. D. A. and Mo. Expt. Sta.). (*Jour. Heredity*, 30 (1939), No. 2, pp. 38-43, figs. 4).—Amphidiploid sectors, involving up to one-third of the plant, occurred in sterile hybrids of *Triticum monococcum* \times *Aegilops uniaristata*, *A. caudata* \times *A. umbellulata*, and *A. speltoides* \times *A. umbellulata* as a result of colchicine treatments administered to the hybrid seedlings. These sectors were male and

female fertile, the height of pollen fertility of the different amphidiploids varying inversely with the degree of pairing in the corresponding diploid hybrids. Little or no morphological difference was found between $2n$ and $4n$ tillers of the same plant, and *T. monocoecum* \times *A. uniaristata* even failed to show a difference in stomatal size or distribution. It is reported also that W. M. Myers, working at State College, Pa., has induced with colchicine a number of tetraploids of *Lolium perenne*.

Inheritance of new sex forms in Cucumis melo L., C. F. POOLE and P. C. GRIMBALL (U. S. D. A.). (*Jour. Heredity*, 30 (1939), No. 1, pp. 21-25, fig. 1).—Following the discovery among Chinese melon introductions of a form with all-perfect flowers, crosses were made between this plant and monoecious and andromonoecious varieties. An examination of the progeny in the F_1 and F_2 generations indicated that the hermaphrodite is genetically double recessive to monoecious. Segregation in the F_2 of the monoecious \times hermaphrodite approximated the phenotypic ratio of 9 monoecious : 3 andromonoecious : 3 gynomonoecious : 1 hermaphrodite. The F_2 of the andromonoecious \times hermaphrodite approximated the expected 3 : 1 ratio.

Inheritance of immunity from virus X (latent mosaic) in the potato, F. J. STEVENSON, E. S. SCHULTZ, and C. F. CLARK (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 4, pp. 362-365).—In graft tests U. S. D. A. seedling 41956 proved immune to at least six strains of this virus. The inheritance of this immunity was studied in crosses of S 41956 with two nonimmune varieties, and in progenies of S 41956 and two other immunes selfed. Of the F_2 of the two crosses 37 percent and of the selfed lines 72-78 percent proved immune. These results can be explained by the usual type of inheritance in autotetraploids. The hypothesis is presented that with the genes *A* and *B* both necessary for immunity, the immunes used as parents in this study had the genetic constitution *AA aa Bb bb* and the nonimmunes *aa aa bb bb*.

[Papers on animal genetics presented before the Genetics Society of America at the 1938 meetings in Richmond, Va., Ottawa, Canada, and Woods Hole, Mass.] (*Genetics*, 24 (1939), No. 1, pp. 67, 69, 70, 72, 74, 75, 76, 79, 90, 91, 92, 93, 94, 98, 99, 102, 111; also in *Genet. Soc. Amer. Rec.*, 7 (1938), pp. 67, 69, 70, 72, 74, 75, 76, 79, 90, 91, 92, 93, 94, 98, 99, 102, 111).—Brief abstracts are presented on the following articles: Dominance in the *B* Series of the Guinea Pig, by H. B. Chase; Not by Genes Alone, by W. F. Dove (Univ. Maine); Linkage in Rats Between Factors Determining a Pathological Condition and a Coat Color, by W. F. Dunning and M. R. Curtis; A Genetic Study of Milk Goats, With Especial Regard to the Occurrence of Hermaphroditism, by O. N. Eaton and V. L. Simmons (U. S. D. A.); The Effect of Ultraviolet Radiation on the Color Pattern of Phenotypes of the Goldfish (*Carassius auratus*), by H. B. Goodrich and J. P. Trinkaus; Breeding Small Flocks of Domestic Poultry for High Fecundity, by F. A. Hays (Mass. State Col.); Inheritance in Rat Caries, by H. R. Hunt and C. A. Hoppert (Mich. State Col.); "Legless"—a New Lethal in Swine, by L. E. Johnson and J. L. Lush (Iowa State Col.); Effect of Inbreeding and Selection on the Frequency of Prostates in Female Rats, by E. Witschi and G. M. Riley; Chromosome Behavior in Relation to Cancer Susceptibility in Mice, by A. Howard; Induced Lateral Size Asymmetry in the Fowl, by S. S. Munro; Determination of Hair Pigments in the Mouse, by S. C. Reed (E. S. R., 80, p. 751); A Study of Individual Versus Group Needs as a Theoretical and an Experimental Approach to Aggriscendence, by W. F. Dove (Univ. Maine); A Study of Pigmentation in the Chick Embryo by Means of Limb Bud Transplantation, by H. L. Eastlick (Univ. Mo.); Types of Cross-Beak in Fowl, by W.

Landauer ([Conn.] Storrs Expt. Sta.); and A New Dwarf Mutation (*dwa*) in *Rattus norvegicus*, by G. W. Woolley and L. J. Cole (Univ. Wis. et al.).

Genetics and live-stock production, F. W. DRY (*New Zeal. Dept. Sci. and Indus. Res. Bul. 64* (1938), pp. 88, figs. 47).—An account of the principles and application of genetics to livestock production.

Variations in the spotting character of "pinto" horses, J. B. HILL. (Pa. State Col.). (*Pa. Acad. Sci. Proc.*, 12 (1938), pp. 33–35, fig. 1).—Contradictory evidence regarding the recessive nature of glass eye, as well as its association with the recessive spotting character, is indicated in two cases of dominant spotting associated with the glass-eye condition.

[**The production of tailless sheep at the South Dakota Station**] (*South Dakota Sta. Rpt. 1938*, pp. 16, 17).—Of 64 lambs born in 1938, none required docking. Ten of the 13 crossbred lambs of no-tail \times Southdown grade parents had tails averaging 3.1 in., and 2 had no tails at all.

Weights and measurements of the parts and organs of mature inbred and crossbred guinea pigs, O. N. EATON. (U. S. D. A.). (*Amer. Jour. Anat.*, 63 (1938), No. 2, pp. 273–295).—Study of the weights and measurements of organs of mature inbred and crossbred guinea pigs showed that some organs, such as the lungs and liver, are directly proportional to live weight, whereas others, such as the heart, spleen, kidneys, adrenals, and testicles, are nearly uniform in weight regardless of the live weights of the animals. The variability in the weights of organs was reduced by determining the ratio to live weight. Some organs from certain families and crosses had characteristic shapes and variability or anatomical peculiarities. In general, ♀♀ had lighter organs than ♂♂, except for the spleen, kidneys, and thyroid. The length of intestines and spleen showed the least variability and little relation to live weight.

The relation of albinism to body size in mice, W. E. CASTLE. (Univ. Calif.). (*Genetics*, 23 (1938), No. 3, pp. 269–274).—Continuing studies of the relation of color genes to size in mice (E. S. R., 76, p. 463), studies of the maximum weight, tail length, and body length at 6 mo. of age of cinnamon, brown, and albino mice segregated from the backcross of cinnamon (*AabbCc*) ♀♀ to albino (*aabbcc*) ♂♂ showed no significant differences in size that could be correlated with the three phenotypes. The albinism and nonagouti genes and their alleles are concluded to be unrelated to body size. Correlations of 0.55 ± 0.01 and 0.26 ± 0.02 between weight and body length and between body length and tail length, respectively, were noted among more than 600 ♂♂ measured.

Selection for tail-spotting in the house mouse, E. F. BARBOWS (*Jour. Herpt. Zool.*, 80 (1939), No. 1, pp. 107–111, fig. 1).—Beginning with mice showing some tail spotting, 10 generations of selection for white spotting on the tail produced mice almost all of which showed white spotting on the distal end of the tails.

The induction by irradiation with neutrons of hereditary changes in mice, G. D. SNELL (*Natl. Acad. Sci. Proc.*, 25 (1939), No. 1, pp. 11–14).—Study of 44 F₁ animals in the irradiation experiments with neutrons (E. S. R., 74, p. 474) showed that there were produced 3 sterile and 3 semisterile ♂♂ and 1 semisterile ♀. No visible recessive mutations were observed.

A new ear defect in pigs: An apparent lethal factor, H. E. ANNETT (*Jour. Heredity*, 29 (1938), No. 12, pp. 469, 470, figs. 2).—The occurrence of lobed-eared pigs in two litters of Tamworths from related parents is noted. Some of the affected pigs had cleft palates and defective hind legs.

Hereditary brachydactylia and allied abnormalities in the rabbit, H. S. N. GREENE and J. A. SAXTON, JR. (*Jour. Expt. Med.*, 69 (1939), No. 2, pp. 301-314, pls. 3).—Deformities involving a shortening or absence of the component parts of the feet which were associated with abnormalities of the ear occurred in the progeny of a purebred English doe and a hybrid buck and in descendants of the first deformed animal. In the F₁ and backcross generations of over 200 progeny each, foot abnormality was found to behave as a simple recessive autosomal character. The occurrence of the defective ears was limited to animals with deformed feet, but the condition occurred in only 27 of 238 backcross progeny. The foot and ear abnormalities were either due to closely linked factors or additional expressions of the same gene. Embryological and histological studies showing that both types of deformities originated in hemorrhage and necrosis of the affected parts, followed by sloughing which was complete at the twenty-fifth day of gestation, favored the single gene explanation.

Inheritance of eggshell thickness in White Leghorn pullets, L. W. TAYLOR and I. M. LIENER (Calif. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 5, pp. 383-396, fig. 1).—Starting in 1932 with a selection of hens producing thin and thick-shelled eggs, respectively, and subsequently mating these with closely related males, two lines of chickens producing significantly different types of eggshells have been established. Continued selection of this type has been ineffective in further differentiation of the two lines or in decreasing the variability of expression of eggshell characters in subsequent generations. Apparently heritable factors were involved in the determination of the amount, thickness, and percentage of eggshell characteristics of individual hens, with evidence that dams have relatively greater influence than sires in determining shell character produced by daughters. Little or no decrease in shell percentage from clutch positions 1 to 2 occurred among females of the thick-shelled line, whereas pullets of the thin-shelled line tended toward a lower shell percentage in the eggs in position 2. Individual variations in this respect occurred in both lines. The percentage of total egg weight represented by eggshell was found to be a satisfactory expression of this character.

Notes on cross-beak in fowl, W. LANDAUER. ([Conn.] Storrs Expt. Sta.). (*Jour. Gehef.*, 37 (1938), No. 1, pp. 51-58, pl. 1).—Four types of cross-beak in fowls are noted. One type was associated with eye defects; one occurred in homozygous creepers; and two types, one present at hatching and on developing later, were hereditary and had a complex mode of inheritance. Cross beak was not a true lethal, but mortality was heavy after hatching. Crossing of the upper beak toward one side or the other seemed more frequent in certain types, but the breeding data did not bear out its hereditary nature. A fifth type of cross beak involving a short but straight upper beak at hatching which later became crossed was also noted.

Estimating the influence of heredity on the tarso-metatarsal length of the domestic turkey, R. G. JAR. (Okla. Expt. Sta.). (*Okla. Acad. Sci. Proc.* [Okla. Univ.], 18 (1938), pp. 11-13).—The tarso-metatarsal length in 511 ♂ turkeys ranged from 6.8 to 8.4 in. and in 505 ♀♀ from 5.2 to 6.5 in. in length. The analysis of variance in the shank length indicated that heredity was responsible for about 25 percent of the variability in ♂♂ and 89 percent of that in ♀♀. The ♀ shank length, therefore, serves as a better measure of breeding progress than that of ♂♂.

Investigation of the blood value of the Yaroslav breed of cattle with reference to productivity, H. F. KUSHNER (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 20 (1938), No. 5, pp. 393-397).—The oxidative capacity of the blood of 270 Yaroslav cattle of different ages, sires, and stages of health

and reproduction was ascertained by methods to which attention was previously called (E. S. R., 80, p. 472). Variations with age and sex were noted. The hemoglobin value was relatively high in aged bulls and in young ♀ calves and pregnant and tubercular cows. Weight and the higher blood values seemed to be correlated. An index of the functional capacity of the blood was calculated for several breeds.

A preliminary note on the study of oestrus in sheep—dioestrous cycle in Bikaner ewes, L. W. SMITH and G. SINGH (*Agr and Livestock in India*, 8 (1938), No. 6, pp. 683-688).—Intervals between services of Bikaner ewes not followed by pregnancies varied from 15 to 19 days. The duration of heat extended to over 24 hr. in some cases.

On the relative roles of increased and constant periods of illumination in the sexual photoperiodic activation of the male starling, J. W. BUREKA (*Jour. Expt. Zool.*, 50 (1939), No. 2, pp. 249-257, pl. 1).—Groups of starlings and juncos under limited light conditions failed to show spermatogenesis unless the days were systematically increased in length above 9 hr. A constant day length of 10.25 hr. would not continue spermatogenesis even though formation of spermatocytes had started.

Mammary activity, H. D. KAY (*Sci. Prog [London]*, 33 (1939), Mo. 131, pp. 476-492).—A review is given of the interaction of various hormones from the ovaries and pituitaries which are related to lactation, including especially oestrone and progesterone, in causing development of the mammary gland and prolactin in relation to the secretion of milk. The probable role of other hormones from these and other glands and their relationship to the precursors of milk are discussed.

The mammary gland of the rhesus monkey under normal and experimental conditions, S. J. FOLLEY, A. N. GUTHRIE, and S. ZUCKERMAN (*Boy. Soc. [London], Proc. Ser. B*, 126 (1939), No. 845, pp. 469-491, pls. 5, figs. 18).—Description is given of the growth, development, and histological changes in the mammary gland of the rhesus monkey and its response to oestrone. Duct proliferation was stimulated in ♂♂ and ♀♀ by oestrone and testosterone propionate administration.

Chemical concentration of mammogen from prehypophyseal tissue, A. A. LEWIS and O. W. TURNER. (Mo. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 3, pp. 435, 436).—Preliminary studies gave evidence that mammogen had distinctly different chemical properties from lactogenic or carbohydrate-metabolism hormones contained in the pituitary gland. Mammogen could be extracted from pituitary tissue by lipid solvents and remained in solution at high concentrations of alcohol. It could be recovered as an oily residue upon the vacuum distillation of the alcohol or ether-alcohol extracting solutions.

Duration of sensitivity of the endometrium during lactation in the rat, R. A. LYON and W. M. ALLEN (*Amer Jour. Physiol.*, 122 (1938), No. 13, pp. 624-626).—Endometrial sensitivity, as measured by the production of deciduomata following injury to the endometrium in rats, was not present until 4 days after parturition. The sensitivity lasted only until the sixteenth day even though suckling and lactation were continued.

The physiology of development of feathers, I, II, F. R. LILLER and M. JUHN (*Physiol. Zool.*, 5 (1932), No. 1, pp. 124-184, pls. 8, figs. 30; 11 (1938), No. 4, pp. 434-450, pls. 12, figs. 2).—These papers deal with the fundamentals of the physiology, development, and growth of feathers. Part 1 deals with the Growth Rate and Pattern in the Individual Feather and part 2 with the General Principles of Development With Special Reference to the After Feather.

Differential gradient functions in the feather germ, R. M. FRAPS (*Physiol. Zool.*, 11 (1938), No. 2, pp. 187-201, figs. 8).—Three orders of pigmentation induced in feathers of the Brown Leghorn male or capon with increasing hormone concentration are described. These are, in terms of loci in the collar of the developing germ, (a) the dorsoventral order previously described in detail by Lillie and Juhn [as noted above]; (b) the ventrodorsal order, which is completely the reverse of (a); and (c) a complex order, proceeding from a medial point in the collar toward both ventral and dorsal collar limits. These orders of pigmentation are interpreted in terms of differential gradient functions, that is, in terms of secondary gradients in the limiting reaction potentials for alternative pigmentation processes. Each of these secondary gradients, or gradient functions, is assumed to vary by differing proportionalities with a given change in primary gradient differentials, which are assumed to remain always the same in direction although varying in absolute values in collar limbs of different germs."

Longer range paternity in sheep, R. W. PHILLIPS, R. G. SCHOTT, and E. M. GILDOW. (U. S. D. A. and Idaho Expt. Sta.). (*Jour. Heredity*, 29 (1938), No. 12, pp. 471-474, figs. 3).—Continuing studies on the artificial insemination of sheep (E. S. R., 79, p. 35), ram semen was transported from Beltsville, Md., to Moscow, Idaho. From 60 inseminations, 37 of which were from 31.5 to 72 hr. old, there were 5 pregnancies. An attempt was made to cool the semen slowly and maintain a temperature of 5° C. during transport.

Selective fertilization in poultry, G. BONNIFÉ and S. TRULSSON (*Hereditas*, 25 (1939), No. 1, pp. 65-76).—Two lots of 5 Rhode Island Red ♀♀ each were inseminated with sperm from Rhode Island Red and White Leghorn ♂♂ on alternate days. There were produced 151 red chicks and 54 white chicks. Inseminations with mixed sperm from both breeds showed that 24 eggs were fertilized by White Leghorn sperm and 88 eggs by Rhode Island Red sperm. The results with the use of semen from the 2 breeds on alternate days showed that the highest frequency of fertilization was for eggs laid 2 days after insemination. Although simple microscopic examination indicated that the sperm from the 2 cocks were equally viable, when only the White Leghorn ♂ was used some hens produced only infertile eggs and others infertile eggs and white chicks. From the conclusions it was impossible to determine whether the individual ♂♂ showed selective fertility with the different ♀♀ or whether racial differences were exhibited.

The sex ratio in wild birds, E. MAYR (*Amer. Nat.*, 73 (1939), No. 745, pp. 156-179).—A summary is given of data on the sex ratio of different species of wild birds. The adult sex ratios show extreme variations from equality in monogamous, polygamous, and polyandrous species which were, in part, correlated with peculiarities of the life history of each species.

Gonad-stimulating abilities of male and female rat pituitary glands, A. A. HELLBATH and R. O. GREEP (*Soc. Expt. Biol. and Med. Proc.*, 38 (1938), No. 5, pp. 902-904).—Injections of acetone dried powder of pituitaries from ♂ rats into immature normal and hypophysectomized ♀♀ induced follicular growth in the ovaries without luteinization, except in a few cases when large doses were administered. Pituitaries from ♀♀ caused luteinization at all dose levels tested.

Visual pathways concerned in gonadal stimulation in ferrets, W. E. LEGLARK, T. McKEOWN, and S. ZUCKERMAN (*Roy. Soc. [London], Proc., Ser. B*, 126 (1939), No. 845, pp. 449-468, pls. 2, figs. 3).—Lesions were made at various levels in the visual pathways of the brains of ♀ ferrets during anoestrus, and study was made of the influence of artificial light in bringing about heat in

these animals. Severing the optic nerves either prevented or delayed the onset of heat as compared with controls. "The experiments showed that the normal response to visual stimulation occurs in the absence of the superior colliculi, when all retinal impulses to any part of the midbrain have been interrupted, and when retinal impulses to the dorsal nucleus of the lateral geniculate body and the visual cortex have been completely interrupted."

Influence of diet on gonad activity of English sparrow, *Passer domesticus* (Linnaeus), J. C. PERRY (*Soc. Expt. Biol. and Med. Proc.*, 38 (1938), No. 5, pp. 716-719).—Development in the testes and ovaries of English sparrows and darkening of the beaks of ♂♂ were induced during the nonbreeding season by feeding wheat exposed for over 250 hr. to ultraviolet irradiation. The induced spermatogenesis and increased size of the ovaries were similar to that resulting from direct irradiation of the birds.

The chemistry and biological significance of the male sex hormones, F. C. KOCH (*Jour. Urol.*, 41 (1939), No. 2, pp. 199-205, figs. 2).—The chemical composition of androgenic substances from different sources is given. Variations in the androgenic and oestrogenic substances in the urine of normal, castrate, and sex-deficient men and women are presented.

Maintenance of spermatogenesis in hypophysectomized mice with androgenic substances, W. O. NELSON and C. E. MERCKEL (*Soc. Expt. Biol. and Med. Proc.*, 38 (1938), No. 5, pp. 737-740, figs. 3).—Continuing studies of the practicability of maintaining spermatogenesis in hypophysectomized rats (E. S. R., 78, p. 323), the authors conducted similar studies on mice with much the same results. Crystalline androgens prevented the marked degenerative changes in the seminiferous tubules of hypophysectomized rats for at least 23 days. Androstenedione was the most effective of the substances tested.

Variations in the reaction of chicks to different methods of administering androgens, W. R. BRENNEMAN (*Endocrinology*, 24 (1939), No. 1, pp. 55-62).—Studies were made of the comparative comb-growth effects induced in capons by different methods of administering Oreton (testosterone propionate) and Oreton-B (dihydroandrosterone benzoate). Both substances were more effective by subcutaneous than by intraperitoneal injection, but Oreton proved less effective than Oreton-B. There was increased comb response from the administration of the two hormones simultaneously. Birds were induced to crow in 7 days after hatching by the administration of Oreton-B and Oreton, but in 5 days with Oreton-B alone.

The comb of the baby chick as a test for the male sex hormone, R. T. FRANK, F. KLEMPNER, and F. HOLLANDER (*Soc. Expt. Biol. and Med. Proc.*, 38 (1938), No. 5, pp. 853-856, figs. 2).—The chick comb test for assaying the ♂ hormone (E. S. R., 78, p. 320) was made more sensitive and found to give more uniform results with chicks 3 days of age injected for 7 days with doses up to 500γ of androsterone in 0.05 cc. of sesame oil than previously when chicks 6 days of age were injected for 10 days with up to 500γ of androsterone in 0.1 cc. of oil. Comb weights plotted against dose had the same slope for ♂♂ and ♀♀, with a slightly higher intercept for ♂♂.

A corpus luteum-stimulating substance in the rat placenta, E. B. ASTWOOD and R. O. GREER (*Soc. Expt. Biol. and Med. Proc.*, 38 (1938), No. 5, pp. 713-716).—The results of several experiments indicated that the fetal rat placenta secretes a substance, different from any known gonadotropic or lactogenic hormone, which is responsible for the maintenance and function of corpora lutea during the latter half of pregnancy. The hormone secreted by the developing chorion evidently maintains and enlarges the corpora lutea after the tenth to the eleventh day of gestation and continues pregnancy to term.

A difference of effect between the oestrogenic hormones and diethylstilboestrol. O. MÖNDAHL (*Nature London*, 143 (1939), No. 3648, pp. 160, 161).—Like other oestrogens, diethylstilboestrol on infection was found to suppress the embryo development induced by testosterone. When administered by injection in combination with testosterone, it did not suppress embryo development as much as to inhibit embryo development from testosterone alone. (The isolation of progesterone and $\Delta^4,20$ -allopregnanolone from ox adrenals, D. BEALL (*Biochem. Jour.*, 32 (1938), No. 11, pp. 1957–1960).—Chemical methods effective in the isolation of progesterone and $\Delta^4,20$ -allopregnanolone from ox adrenals are described. J. A. A. (1938) 118. 119. 120. 121. 122. 123. 124. 125. 126. 127. 128. 129. 130. 131. 132. 133. 134. 135. 136. 137. 138. 139. 140. 141. 142. 143. 144. 145. 146. 147. 148. 149. 150. 151. 152. 153. 154. 155. 156. 157. 158. 159. 160. 161. 162. 163. 164. 165. 166. 167. 168. 169. 170. 171. 172. 173. 174. 175. 176. 177. 178. 179. 180. 181. 182. 183. 184. 185. 186. 187. 188. 189. 190. 191. 192. 193. 194. 195. 196. 197. 198. 199. 200. 201. 202. 203. 204. 205. 206. 207. 208. 209. 210. 211. 212. 213. 214. 215. 216. 217. 218. 219. 220. 221. 222. 223. 224. 225. 226. 227. 228. 229. 230. 231. 232. 233. 234. 235. 236. 237. 238. 239. 240. 241. 242. 243. 244. 245. 246. 247. 248. 249. 250. 251. 252. 253. 254. 255. 256. 257. 258. 259. 260. 261. 262. 263. 264. 265. 266. 267. 268. 269. 270. 271. 272. 273. 274. 275. 276. 277. 278. 279. 280. 281. 282. 283. 284. 285. 286. 287. 288. 289. 290. 291. 292. 293. 294. 295. 296. 297. 298. 299. 300. 301. 302. 303. 304. 305. 306. 307. 308. 309. 310. 311. 312. 313. 314. 315. early melilotus, cowpeas, mat beans, and Calcarata vetch; biochemical studies of forage plants; effects of burning range brush; and weed control research dealing with chlorate herbicides, soil sterilization with arsenicals and borates, injection of carbon disulfide to kill roots of perennials, as morning-glory, use of sulfuric acid and Sinox as selective weed sprays, and acid-arsenicals and other translocated weed sprays. Productive varieties or strains of wheat, barley, grain sorghum, Sudan grass, beans, and cowpeas developed by the station are recorded.

[Field crops work in Delaware], G. L. SCHUSTER, C. E. PHILLIPS, and M. W. GOODWIN (*Delaware Sta. Bul.* 214 (1938), pp. 11, 12, 13, 21).—Brief reports are made on fertilizer experiments with wheat, yield tests of corn hybrids and varieties, trials of barley varieties and soybean selections, selection and improvement of Korean lespedeza, and the value of grass and grass drying.

[Field crops research in Florida]. (Partly coop. U. S. D. A. and Ga. Coastal Plain Expt. Sta.). (*Florida Sta. Rpt.* 1938, pp. 39-45, 46, 46-59, 78, 79, 104, 152, 153, 156, 157-163, 176, 178-181, 182, 183, 186-188, 189, 195, 196, figs. 9).—Reports of progress are made from continued investigations (E. S. R., 79, p. 469) at the station and substations by F. H. Hull, W. A. Carver, W. E. Stokes, G. E. Ritchey, W. A. Lenkel, R. M. Burnette, J. P. Camp, J. D. Warner, H. H. Hume, R. E. Blaser, A. L. Shealy, W. G. Kirk, F. B. Smith, R. V. Allison, H. W. Winsor, F. S. Jamison, J. R. Beckenbach, J. R. Neller, W. T. Forsee, F. T. Boyd, T. Bregger, R. W. Kidder, F. D. Stevens, R. R. Kincaid, W. M. Fifield, H. S. Wolfe, and W. F. Ward, including breeding work with corn, oats, Napier grass, sea-island cotton, sugarcane, tobacco, and peanuts; variety tests with corn, oats, rye, grain sorghum, sorgo, sugarcane for sugar and sirup, potatoes, peanuts, cowpeas, soybeans, clover, and miscellaneous forage and pasture grasses and legumes and cover crops; production tests with ramie and ginger lily; variety, adaptation, and fertilizer tests with sea-island cotton; fertilizer tests with corn, oats, potatoes, ramie, peanuts, clovers, Dallis grass, and carpet grass; study of the development and deterioration of roots in relation to growth of pasture plants under different fertilizer and cutting treatments; response of corn and beans on Everglade soils to less common elements; composition factors affecting the value of sugarcane for forage and other purposes; physiology of the blooming of sugarcane; cultural tests with potatoes, corn, peanuts, velvetbeans, and cover crops; methods of inoculating legumes (white clover) in Florida soils; comparative production of pearl millet, sorgo, Napier grass, and Guyana sugarcane when grown for silage at relatively high fertility levels; germination of tobacco seed after 6 yr. in different types of storage, and tobacco planted fertilization; cowpeas and soybeans grown in rotation for summer cover and green manure; and crop rotation studies under Everglades conditions with corn, cotton, crotalaria, and Austrian winter peas, and corn and runner peanuts rotating with crotalaria and with native cover crops.

Additional pasture research included comparisons of native v. improved pastures, burned v. unburned native pastures for both 9 and 12 months' grazing, and of methods of land preparation previous to seeding improved pastures; effects of different fertilizer formulas on yields of Bahia and centipede grasses; the effect of fertilizers on the yield, grazing value, chemical composition, and botanical make-up of pastures; eradication of weeds in tame pastures and methods of ridding land of objectionable growths and obstacles; forage nursery and plant adaptation studies, and forage and pasture grass improvement; a grazing test comparing various grasses grown on cut-over sand hill land; growth behavior and relative composition of range grasses as affected by burning and the effect of burning on maintenance of natural grass stands and upon the estab-

lishment of improved grasses; studies of pasture legumes, of Napier grass for pasture purposes, and of water pasture; methods of establishing permanent pastures under various conditions; and pasture studies on peat and muck soils.

[**Agronomic work in North Dakota**]. (Partly coop. U. S. D. A.). (*North Dakota Sta. Bmo. Bul.*, 1 (1939), No. 4, pp. 3-6, 10-15, 20-29, figs. 3).—Articles reporting progress results include Hybrid Corn for North Dakota (pp. 3-6) and Which Corn Hybrids Are Useful in North Dakota? (pp. 23-25), both by W. Wildakas; Durum Wheat Breeding, by G. S. Smith (pp. 10-12); Small Grain Varieties for North Dakota, by T. E. Stoa (pp. 12, 13); Why Grow Flax, by T. H. Hopper (pp. 13-15); Russian Knapweed in North Dakota, by E. A. Helgeson (pp. 20-23); and Seeding Grasses and Legumes for Pasture and Hay, by W. Whitman, T. E. Stoa, and H. C. Hanson (pp. 25-29).

[**Agronomic work in South Dakota**], A. N. HUME, F. J. LEBLANC, and T. R. WRIGHT. (Partly coop. U. S. D. A.). (*South Dakota Sta. Rpt.* 1938, pp. 7-11, 40).—Field crops investigations (E. S. R., 79, p. 473), reported on briefly, comprised breeding work with corn, durum and spring and winter hard red wheats, oats, barley, and alfalfa, and with sorghum for low hydrocyanic acid content; crop rotations for bindweed control; tests of barley and oats varieties; and an investigation of the possibilities of *Ephedra sinica* as a drug plant with a tendency to prevent soil erosion.

[**Field crops research in Washington**], E. G. SCHAFER, O. E. BARBEE, O. A. VOGEL, E. F. GAINES, W. HERMANN, W. A. HARVEY, D. C. SMITH, C. L. VINCENT, J. C. DODGE, W. J. CLORE, H. D. JACQUOT, H. P. SINGLETON, C. E. NELSON, C. A. LARSON, A. J. JOHNSON, and R. F. SACKMAN. (Partly coop. U. S. D. A. and Idaho Expt. Sta.). (*Washington Sta. Bul.* 368 (1938), pp. 10-12, 14-16, 49, 50, 73-79, 82-84, 92).—Agronomic experimentation (E. S. R., 79, p. 323), reported on from the station and substations, included variety tests with spring and winter wheat, barley, oats, rye, corn (and hybrids), potatoes, sugar beets, seed flax, alfalfa, sweetclover, grasses, and mixtures of forage crops; breeding work with barley, oats, wheat, sweetclover, potatoes, and forage grasses; a study of the effect of storage temperature and atmospheric composition upon sugar accumulation, sprout production, and weight loss of potato tubers; cultural (including planting) studies with wheat, oats, flax, crested wheatgrass, alfalfa, and sugar beets; wheat as a nurse crop with crested wheatgrass; tillage and soil moisture studies, with moisture usage by peas, wheat, and crested wheatgrass; fertilizer tests with alfalfa, sugar beets, beans, and with potatoes, corn, and wheat in rotation; crop rotations, including permanent fertility and organic matter maintenance studies; and weed control experiments.

A comparative study of the subterranean members of three field grasses, H. J. DITTMER (*Science*, 88 (1938), No. 2290, p. 483).—As indicated by their relative total numbers, lengths, and areas of roots and root hairs, Kentucky bluegrass was considered far superior to rye and oats, in order, for soil binding and retarding erosion.

The emergence of grass and legume seedlings planted at different depths in five soil types, R. P. MURPHY and A. C. ARNY. (Minn. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 1, pp. 17-28).—The total and rates of emergence were determined for five grasses and five legumes planted 0, 0.5, 1, 2, and 3 in. deep on five soil types in the field and greenhouse.

Planting depth was found to be the major factor determining total emergence of seedlings of individual crops. About 0.5 in. deep was satisfactory for the species used, although surface planting produced good stands under conditions ideal for emergence. Timothy and crested wheatgrass made optimum stands in the field from 0.5-in. depth while plantings 1 in. deep were not so satisfactory,

respectively on Clinton silt loam and Beed canary grass planted 4 in deep emerged well on all soil types, and bromegrass emerged satisfactorily from the 2-in. depth on all soils except Clinton silt loam. Alfalfa and sweetclover produced uncertain stands at 1-in. depths in the field on all soil types except Fargo silty clay loam. Red clover made satisfactory emergence at 1-in. depths on all soil types. It appeared that bromegrass can be mixed and sown with grain crops if no other satisfactory seeding method is available, if not only seed weights of 18 species of grasses and legumes tested in the greenhouse on all soil types showed a significant positive correlation with total emergence from 2- and 3-in. planting depths were equal or more (5-11 in. total 11.7). Surface plantings gave the highest percentage of emergence for all crops on Carrington heavy silt loam and on Clinton silt loam. For the field/total emergence was definitely greater from the 0-1-in. plantings than from surface plantings on Fargo silty clay loam and Merrinac loamy fine sand. Total emergence from the deeper plantings was somewhat higher on Fargo silty clay loam than on other soils and was lowest on Clinton silt loam. Environmental conditions influenced rate of emergence more than the other variables. Emergence was nearly complete 15 days after planting for all species. The legumes reached maximum emergence about 15 days before the grasses, indicating that conditions desirable for emergence must continue somewhat longer after planting for grasses than for legumes.

Native and adapted grasses for conservation of soil and moisture in the Great Plains and Western States. M. M. Hooten (Bull. Dep. Agr. Farmers' Bul. 1812 (1939), pp. 1-44, figs. 103). The characteristics, distribution, use, value for erosion control, and planting practices are described for 30 grasses, including blue wheatgrasses, buffalo grass, bluestems, grama, Bermuda grass, birdseye, *Hilaria* spp., Sudan grass, bluegrasses, panic grasses, downy woodpeck and seedgrasses. Special equipment used in collecting, cleaning, and planting and the processing of native grass seed are described and illustrated.

Grass culture and range improvement in the central and southern Great Plains. A. S. Aaron (U. S. Dep. Agr. Circ. 621 (1939), pp. 50, figs. 23). The results of limited grass investigation made by the division of the central and southern Great Plains during the past 50 years together with general observations by research workers in the region are reviewed and used as a basis for tentative suggestions on grass culture and range improvement. Adapted and sand grasses and other grasses and plants are described, with comments on their characteristics and merits. The bibliography comprises 76 titles regarding native and introduced grasses and their uses.

Detailed surveys at 11 locations in the region showed that from 25 to 40 per cent of land were needed in the past for abandoned farm land to revert naturally to a good stand of native grasses. However, natural recovery may be hastened effectively by, using properly established, well-adapted grasses, and taking advantage of favorable growing seasons. In most of the region where soil blowing is severe, high-out stubble or close drilled Sudan grass affords a satisfactory seedbed for perennial pasture grasses. Blue grama, buffalo grass, side-oats grama, gulch grass, and several other adapted grasses may be seeded alone, in mixtures with each other, or in conjunction with seedlings of buffalo grass more successfully than with native crops. Most adapted grass species may be sown to best advantage medium early in the spring, although winter-growing grasses respond better when seeded in the fall or early in the spring. Combination of drilling and broadcast seeding at about 1-in. depth offers possibilities for better stands of perennial grasses than either method alone. Clipping at about 8-in. high is advised for weed control on newly seeded areas,

and livestock should be excluded during the first growing season and part of the next from regressed areas.

Re-seeding of depleted pastures is more difficult than on cultivated land, but may succeed in favorable seasons when adapted seed is sown early in the morning, before weeds and other plants start growth. Mowing has controlled and sagebrush on native pastures and improved the growth of associated grasses. Deferred and rotation grazing offers the surest means of improving badly damaged pastures and maintaining them in thrifty condition.

Pasture improvement in the Gulf coast prairie of Texas, R. H. STRANGLER, E. B. REYNOLDS, and J. H. JONES (*Texas Sta. Bul.* 570 (1939), pp. 13).—Experiments with pasture and forage plants over 25 yr. at Angleton led to the recommendation of Dallis, Bermuda, carpet, and Angleton grasses, California bur-clover, White, Dutch, clover, and common lespedeza for permanent pastures in the Gulf coast prairie region. Adequate drainage, mowing to control weeds, and seeding of desirable and adapted pasture plants contributed to the establishment of good improved pastures while the use of fertilizers was not profitable. To establish a good sod with seeding and mowing, 2 yr. were needed, and 1 yr. with mowing alone. The seeded pasture contained more kinds of grasses in a more uniform mixture than the mowed pasture. Mowing twice a year resulted in the gradual replacement of the tall-growing bluestem grasses by lower-growing grasses and legumes, as Bermuda grass, carpet grass, and lespedeza.

Improved permanent pasture had a greater carrying capacity and produced more total gain per steer yearly than unimproved native pasture. Steers on native pasture gained faster in early spring and reached their highest condition in June, while steers on improved pasture continued to gain during the summer and fall and reached their highest condition in October. The better results on improved pasture were ascribed to the more nutritious herbage and to the longer productive grazing period.

When grown in pure stands, native bluestem grasses produced higher forage yields than Bermuda, carpet, Dallis, and Angleton grasses. All of these grasses except Bermuda yielded more when cut at maturity than when harvested at monthly intervals, but the young succulent growth of monthly harvested grasses contained more protein, fat, phosphorus, and calcium and was decidedly more palatable than growths harvested at maturity. Bermuda, Dallis, and Angleton grasses, when harvested at monthly intervals, contained enough phosphorus for the nutrition of livestock, while carpet grass and native grass did not. When mature, none of the grasses contained enough phosphorus for adequate nutrition. Only native grass appeared to be deficient in calcium content at any growth stage. Soft grasses of relatively low feeding value was superior to the mature and dead native grasses.

Crop rotation studies. G. H. BAKER and K. H. WILKES (*Idaho Sta. Bul.* 227 (1938), pp. 31, figs. 12).—Yield data are reported from crop rotation experiments at Moscow 1915-37, Sandpoint 1924-32, Teton 1925-37, and Aberdeen 1929-37, and characteristics of rotations applicable to conditions in different parts of Idaho are discussed.

Trend evaluations (E. S. RAY, 80, p. 474) indicated yield expectations with similar sequences of cropping begun under comparable environmental conditions. High-yielding plots in the various rotations generally also showed relatively high upward yield trends while the lower yielding plots showed either low or definite negative trends. Manure in rotations at Moscow led to significant yield increases in all crops except peas. Direct effects of variable crops and fallow preceding wheat in 3-yr. rotation systems containing wheat and

oats as common crops were illustrated by the relative performances of wheat continuously at 100, after fallow 246, potatoes 220, peas 202, corn 154, and sunflower 113. Exact evaluations of the variable crops in their respective effects on wheat yields in the different rotations differ somewhat, yet their relative effects remain the same regardless of the periods of comparison and whether or not the rotation included manure. Wheat yields in the wheat, oats, pea, and the wheat, oats, fallow rotations showed the economy of substituting peas, at least in part, for fallow. Oats yielded highest in the wheat, oats, pea, rather than in the wheat, oats, fallow rotations.

Four-year rotations at Aberdeen showed the influences of alfalfa, in particular, and red clover and peas in the rotation on yields of potatoes and wheat with and without manure. Crop yields in the different rotation systems indicate that, up to the present, availability of moisture rather than soil fertility is the main limiting factor to profitable crop production in the Tetonia area.

1937 report of the uniform alfalfa nurseries, H. L. WESTOVER and H. M. TYSDAL (*U. S. Dept. Agr., Bur. Plant Indus.*, 1938, pp. [1]+16).—Observational data on recovery, fall growth, seed production, and leaf spot, and resistance to bacterial wilt on numerous strains of alfalfa are compiled, and yields relative to Grimm are reported from nine stations. Yields of Ladak, Hardigan (A68), and Baltic were slightly higher than yields of Grimm and yields of Hardistan were lower, resembling results on a number of field plot tests.

Extension of alfalfa roots into subsoil dried by a previous crop, W. H. METZGER and C. O. GRANDFIELD. (Kans. Expt. Sta. and U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 30 (1938), No. 1, p. 80).—Plots on old alfalfa land from which subsoil moisture had been removed to about the wilting coefficient to depths of about 20 ft. were fallowed from one summer to 5 yr. before reseeding to alfalfa. A plot fallowed one summer and since holding a 4-year-old stand had accumulated water to a depth of 8 ft. or less before the new seeding, and roots could not be traced below depths from 10 to 12 ft. except in old root channels. In a plot fallowed 3 yr. before reseeding and bearing a 2-year-old stand, moisture was regained to above wilting coefficient throughout the depth dried out by previous alfalfa, and roots could be traced down to from 19 to 20 ft. deep.

Immediate effect of cross pollination on the carotenoid pigments in the endosperm of maize, I. J. JOHNSON and E. S. MILLER. (Minn. Expt. Sta.). (*Cereal Chem.*, 16 (1939), No. 1, pp. 88-92).—Further study on the magnitude of differences among inbred lines of corn in concentrations of total carotenoid pigments (E. S. R., 80, p. 324) included a survey in 1937 with a larger series of inbred lines, and a study to determine immediate effects on the endosperm of cross-pollination between groups of high and low carotenoid-pigment strains.

Significant variations were found to occur with reference to carotenoid-pigment concentration of the 35 inbred lines studied. When inbred lines were grouped into dark, medium, and light yellow in endosperm color, the difference in total carotenoid pigments was significant only between the dark and light groups. Crossed seed derived from high female \times low male and low female \times high male was significantly different from the female parent, indicating that carotenoid pigments are subjected to the usual xenia effects. The lack of significant correlation between concentration of carotenoid pigments in endosperm of inbred lines and that in leaf tissues (E. S. R., 80, p. 761) suggested that the two are due to independent factors or physiological processes.

The importance of corn hybrids to the corn industry, M. T. JENKINS. (U. S. D. A.). (*Contrib. Iowa Corn Res. Inst. [Iowa Sta.]*, 1 (1939), No. 2, pp. 208-212).—The status and prospects of the production of hybrid corn are re-

viewed, with comments on methods used, characteristics and possible commercial advantages of hybrid corn, and on recent findings in research with the crop.

Hybrid corn in Kansas, R. W. JUGENHEIMER. (Coop. U. S. D. A.). (*Kansas Sta. Circ.* 196 (1939), pp. 20, figs. 13).—Methods followed in the cooperative development of corn hybrids are outlined, with information in part derived from Iowa Station Bulletin 366 (E. S. R., 78, p. 620) on the commercial production of hybrid corn and precautions in its use to be observed by the grower.

Measuring hybrid corns for Michigan, A. R. MARSTON (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 3, pp. 151-160, figs. 4).—Several corn hybrids and varieties are indicated for each of the corn-growing zones of Michigan from results of the cooperative tests, 1935-38, reported. Hybrids of proven value certified by the Michigan Crop Improvement Association, described with adaptations, include Michigan Hybrids Nos. 561 and 1218 and Minnesota Hybrid No. 402, all noted earlier (E. S. R., 79, p. 46), and Wisconsin Hybrids Nos. 606 and 645. Wisconsin Hybrid No. 606 matures about 4 days earlier than Michigan Hybrid No. 561, may be used for silage in the same general region and for grain production, and is adapted to southern Michigan. Wisconsin Hybrid No. 645 is slightly later and more productive than Wisconsin Hybrid No. 606 where it will mature.

A brief discussion of the history of cotton: Its culture, breeding, harvesting, and uses, H. B. BROWN (*Baton Rouge: La. State. Dept. Agr. and Immigr.*, 1938, 4, c.d., pp. 15, [figs. 4]).—A popular treatise.

Cotton growing in the Philippines, A. ELAYDA and F. DE JESUS (*Philippine Jour. Agr.*, 9 (1938), No. 1, pp. 119-133, pls. 4).—Practical information is given on varieties, soil and climatic needs, producing areas, cultural methods and field practices, production costs, and cotton insects and diseases and their control. See also an earlier note by Espino (E. S. R., 45, p. 738).

First Conference of Scientific Research Workers on Cotton in India, March 1937, Papers Read and Summary of Proceedings (*Bombay: Indian Cent. Cotton Com.*, 1938, pp. [1]+444, pls. [30]).—Report is made on the proceedings of the conference held in Bombay, March 4-6, 1937. Papers of interest to agronomists, plant breeders, and technologists included Watering Experiments on Cotton at the Cotton Research Station, Risalewala, Lyallpur, by M. Mohammad Afzal (pp. 86-97); Note on Factors in the Acclimatization of Exotic Varieties of Cotton in Sind (pp. 98-118), and The Cotton Leaf as an Index of the Physiological Requirement of the Cotton Plant (pp. 119-125), both by B. M. Dabral; Cotton Agronomy, by M. U. Barakzai (pp. 126-133); The Saline Soils of Sind and the Cotton Plant, by M. A. Shama Iyengar (pp. 134-138); Influence of Twist on Yarn Strength, by N. Ahmad and V. Venkataraman (pp. 153-176); The Deterioration of Broach Palej Cotton on Storage, by A. N. Gulati (pp. 177-194); Spinning Tests With New Strains of Hyderabad-Gaorani (*Gossypium indicum* Lamk.) Cotton Grown in Successive Seasons or in Different Localities (pp. 195-203), and Cotton Problems of Hyderabad State (pp. 263-278), both by K. Sawlney; Effects of Rainfall on the Quality of Indian Cottons, by R. S. Koshal and N. Ahmad (pp. 204-262); Breeding for Wilt Resistance in Cotton, by B. N. Uppal (pp. 279-295); The Genetics of *Gossypium* and Its Application to Cotton Breeding, by J. B. Hutchinson, P. D. Gadkari, and M. A. Ansari (pp. 296-327); Some Aspects of Cotton Breeding Work in India, by V. Ramanatha Ayyar (pp. 328-340); Advantages and Disadvantages of the Back-Cross Method in Plant Breeding, by S. J. Patel (pp. 341-345); The Distribution of *Gossypium* and the Evolution of the Commercial Cottons, by J. B.

Hutchinson (pp. 347-368); Floral Anatomy as an Aid to the Classification of Cottons, by P. Abraham and V. Ramanatha Ayyar (pp. 369-379); Breeding of Improved Strains of Cotton Suited to Local Conditions, With Particular Reference to Sind and Their Extension, by K. I. Thadani (pp. 380-392); Some Effects of X-Rays on Uppam and Karunganni Cottons, by V. Ramanatha and R. Balasubramania Ayyar (pp. 393-400); Cotton Breeding in the Central Provinces and Berar, by D. N. Mahla (pp. 401-409); The Delimitation of Areas for Strains of Agricultural Crops, With Special Reference to Cotton, by V. G. Parse (pp. 411-423); and Discussion of Sampling Methods in Developmental Studies on Cotton and the Statistical Treatment of Results, by M. Vaidyanathan (pp. 424-436).

Papers on cotton entomology included The Control of Pink Bollworm (*Platyedra gossypiella* Saund.), by P. B. Richards (pp. 8-35); Carry-Over of Pink Bollworm (*Platyedra gossypiella* Saund.) Through Soil in the Mahratwadda Division of the Hyderabad State, by H. D. Nangpal (pp. 36-53); A Brief Account of the Investigation on Spotted Bollworms in South Gujarat, by R. P. Deshpande (pp. 54-65); The Cotton Jassid, by M. Afzal Husain (pp. 66-77); and Preliminary Observations on the Distribution, Food Plants, and Original Home and Habitat of *Pemphres affinis* Fst., the Cotton Stem Weevil of South India, by P. N. Krishna Ayyar (pp. 78-83, 442-444).

A compilation of information on kudzu, I. E. Mues and E. E. Gross (*Mississippi Sta. Bul. 326 (1939), pp. 14, figs. 11*).—Information compiled from reports of experiments by State experiment stations and other sources covers the uses of kudzu (*Pueraria thunbergiana*) for erosion control, soil improvement, and shade, grazing, hay, vegetating water terrace disposal systems, and road bank protection.

[Potato production research] (*Ind. State Veg. Growers' Assoc., [Ann. Rpt.], 9 (1938), pp. 24-38, 53-58*).—Recent research with the potato crop is described in papers entitled New Developments in Potato Production, by E. V. Hardenburg (pp. 24-27) (Cornell Univ.); To Spray or Not to Spray (pp. 27-30), What the Ohio Experiment Station Has Learned About Growing Potatoes on Muck Soil (pp. 33-38), and Large Scale Potato Production on Muck in Ohio, New York, and California (pp. 53-58), all by J. Bushnell (all Ohio Expt. Sta.); and Potato Production on Mineral Soils, by W. B. Ward (pp. 30-32), and New Varieties and Old, by N. K. Ellis (pp. 32, 33) (both Purdue Univ.).

The role of green manures in potato production, E. R. Purvis and J. M. Blume (Va. Truck Expt. Sta.). (*Amcr. Potato Jour., 16 (1939), No. 2, pp. 82-86*).—Beneficial effects of green manures of soybeans and sorghum upon potato yields on two soil types are reported. Fresh organic matter was about three times as effective in increasing yield as was residual organic matter. It was shown that green manure crops add plant nutrients to the soil in amount about equivalent to 1 ton per acre of a 7-2-5 fertilizer.

Twenty-five years in the history of the potato, F. A. Kranz. (Minn. Expt. Sta.). (*Amcr. Potato Jour., 16 (1939), No. 2, pp. 25-31*).—Advances in potato improvement are summarized with remarks on progress in other phases.

The Pontiac potato, H. C. Moore and E. J. Wheeler (*Michigan Sta. Quart. Bul., 21 (1939), No. 3, pp. 174, 175*).—Pontiac, a seedling potato chosen by the station from among progeny of a Katahdin (E. S. R., 74, p. 630) × Bliss Triumph cross (made in 1930 by the U. S. Department of Agriculture), is a late-maturing red potato, round to oblong shape, with medium deep eyes and crisp white flesh, and its plant has large, dark green, rough-textured leaves and makes vigorous upright growth. It has not shown marked resistance to insect

and disease attacks but has not been much more susceptible than the standard varieties. Mosaic has been the major virus disease observed in Pontiac plots. In some trials in Michigan and Iowa Pontiac proved more drought-resistant than other varieties and was freer from hollow heart and misshapen tubers. On muck plots at East Lansing, 1936-38, Pontiac usually outyielded other varieties, and on sandy loams in 1937 and 1938 it averaged slightly better than Russet Rural and Katahdin and about the same as Chippewa in yields of U. S. No. 1 potatoes. It has been grown in trial plots in Florida, Louisiana, Iowa, and North Dakota with encouraging results.

A preliminary report on the waxing of seed potatoes. E. V. HARDENBURG and H. PLATENIUS. (Cornell Univ.). (*Amer. Potato Jour.*, 16, (1939), No. 2, pp. 37-40).—Treatment of Heavyweight (Smoothen Rural) seed potatoes with a 30-percent 231-B wax emulsion while still in a dormant condition, resulted in stimulation of sprout growth, earlier emergence of plants, and a corresponding increase in yield, these results seeming due to conservation of moisture, accompanied by sprout growth stimulation in the treated tubers. Beneficial effects of waxing appeared similar to those produced by green sprouting. Further studies would determine effects of waxing on respiration of seed treated immediately after harvest and on subsequent yield.

Bruising, freezing, and chemical injury of potatoes in transit. R. C. WRIGHT (U. S. Dept. Agr., Tech. Bul. 668 (1939), pp. 23, figs. 13).—Injury to potatoes next to floors or floor racks and in some cases next, side walls, in carlots of sacked potatoes, sometimes attributed to freezing or to damage from chemicals on the floor or walls, appears primarily to result from mechanical bruising against the floor or side walls caused by the load weight, and air movement. The several types of injury are described and illustrated. In simulated transit tests to determine effects of storage treatment and tuber temperature on susceptibility to floor bruising, 65 percent of the potatoes in lots from storage at 32° F. for 3 mo. were injured, 31 percent of those from a 50° storage were injured, and 54 percent of potatoes from cellar storage at about 50° and subsequently held for 3 days at 32° before the test were injured. Transit bruising under experimental conditions was identical with that under commercial conditions. Chemical injury occurred only in cases where the skins of potatoes were broken when in contact with soluble chemicals, showing that it was secondary to mechanical injury. Freezing injury usually occurred independently of injury from bruising.

Early cutting and fertilization of quack grass meadows. S. T. DRYDA and D. L. CLANAHAN (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 3, pp. 176-179).—Quack meadows in cooperative tests, 1936-38, in the Michigan Upper Peninsula when treated about May 1-7 with 200 lb. of ammonium sulfate per acre broadcast and cut early, June 17-25, produced about double the yield of protein (9.13 v. 6 percent) and about 0.5 ton per acre more hay of better quality than unfertilized meadows cut late, July 8-15, the current practice. Relatively little increase in yield was obtained by permitting fertilized hay to stand until late cutting, while the quality decreased markedly. The merits of this practice and of growing a crop of alfalfa are compared.

Hydrocyanic acid content of sorghum varieties. J. F. COUCH, R. R. BERRY, and J. H. MARTIN, (U. S. D. A.). (*Jour. Wash. Acad. Sci.*, 29, (1939), No. 4, pp. 146-161).—Plant and leaf samples of 33 sorghum varieties grown at one or more stations in the Great Plains area (1936-37), analyzed at various growth stages, gave HCN contents of the dried leaves ranging from about 12 to 75 percent of that of the whole green plant. It appeared that any variety tested may

at times contain sufficient HCN to be toxic to animals. There was some tendency for the content to be high where summer precipitation was lowest, but there was no consistent relation with temperature.

A brief discussion of the history of sugar cane: Its culture, breeding, harvesting, manufacturing, and products. W. G. TAGGAET and E. C. SIMON (*Baton Rouge: La. State Dept. Agr. and Immigr.*, 1938, 3. ed., pp. 20, [figs. 4]).—Popular information is given on the history and production of sugarcane and its products in Louisiana.

The timothy crop. M. W. EVANS (*U. S. Dept. Agr. Leaflet 171* (1939), pp. [1]+6, figs. 2).—Practices for growing timothy for hay, pasturage, silage, and seed (E. S. R., 75, p. 338) are outlined, with information on adaptation, improved varieties (E. S. R., 70, p. 179), use, and feeding value.

Relation of latitude to the growth of timothy. M. W. EVANS. (U. S. D. A.). (*Amer. Jour. Bot.*, 25 (1938), No. 10, p. 48).—Plants of 9 selections of timothy, ranging by fairly uniform gradations from very early to very late, were grown at 10 stations at intervals from Gainesville, Fla., to Fort Vermilion, Alta. In the South selections which were progressively later had progressively shorter stems, but in the North stems of later selections grew to as great or even greater lengths than those of early selections. The season for blooming for the earliest selections progressed northward as the season advanced. For the latest selections, which need a longer day than earlier ones for development of culms and inflorescences, blooming occurred first at some midlatitude. From this latitude the season for blooming progressed both northward as the temperatures became suitable for growth and southward as the number of hours of daily illumination gradually increased. At a southern station late selections produced smaller hay yields than early selections which are better adapted to the relatively short days occurring there, but at a northern station both early and late selections produced relatively large yields. See also an earlier note (E. S. R., 74, p. 193).

Factors that influence the injury to wheat from freezing. R. B. HARVEY. (Univ. Minn.). (*Northwest. Miller*, 197 (1939), No. 4, Sect. 1, pp. 22, 23).—Freezing tests were made on plants of Thatcher, Ceres, and Marquis spring wheats and Minturki winter wheat taken in sods from wheat fields when in the boot and heading stages. When held at 22°, 25°, and 28° F., the leaves froze first in all tests, and then the spikes and finally the stems froze. Stem internodes were the most resistant. Freezing began at the tops of stems before the bases, and top leaves froze before bottom leaves. In general, wheat in these two stages had all the leaves and spikes killed at 22°, whereas stems showed up to 50 percent survival. The extent of injury to stems was decreased at 25° to one-fourth or less, and leaves and spikes seven-eighths or less. At 28° the stems mostly remained unfrozen, but leaves and spikes were at least one-eighth frozen. The neck just below the spike seemed to be especially sensitive to freezing. Injury after freezing was confined to cell areas actually frozen, but after 3 days tissues depending on frozen tissues for transport of water and food materials dried up. Variety, relative hardened condition of plant, waxy covering on leaves and stems, concentration of sugars in cell sap, and types of freezing weather endured are discussed briefly in relation to freezing injury.

A critical study of technique for measuring granulation in wheat meal. W. W. WORZELLA and G. H. CUTLER. (Ind. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 5, pp. 329-341, figs. 2).—Meal granulation or degree of particle fineness, regarded as an important component of wheat quality, is of considerable interest to the miller, cereal chemist, geneticist, and plant breeder. Experiments on a critical study of technic for measuring meal granulation were con-

ducted with Michikof, Michigan Amber, and Purdue No. 1 wheats over 2 yr., during which more than 2,000 samples were sifted.

The following technic was adopted from results obtained in a systematic study of 11 steps in the procedure. Ten gm. of clean, sound, normal wheat containing about 10 percent of moisture are ground into a fine meal. Immediately after grinding a 2.5-gm. sample is weighed and transferred to the larger sieve (60- and 270-mesh sieves) and sifted for 1 hr. in the granulometer. The weight of material that passes through the finer sieve or into the pan is expressed as percentage of total and is designated as particle-sized index. A low index indicates a coarse meal and a higher index indicates a relatively finer meal. A new apparatus developed—the granulometer—and the nature of meal fractions are illustrated and described.

Inspection of agricultural seeds, H. R. KRAYBILL ET AL. (Coop. U. S. D. A.). (*Indiana Sta. Circ.* 239 (1938), pp. 127, fig. 1).—The purity, germination, and weed seed contents, and for legumes the hard seed contents are tabulated from tests of 1,381 official samples of seed collected from dealers in Indiana during the year ended June 30, 1938.

Seed inspection, F. A. McLAUGHLIN (*Massachusetts Sta. Control Ser. Bul.* 96 (1938), pp. 102).—The purity, germination, and weed seed contents are tabulated for 273 official samples of field crops seed and mixtures and germination for 560 samples of vegetable seed collected in Massachusetts during the year ended December 1, 1938. Results of type and performance studies with seed oats, in cooperation with W. G. Colby; and field tests for trueness to type and variety on 120 lots of beans, beets, carrots, endives, lettuce, onions, parsnips, peas, radishes, spinach, and Swiss chard, in cooperation with G. B. Snyder, are included, with remarks on the quality of onion seed produced in the Connecticut Valley in the 1937 season and cleaning tobacco seed for growers. Studies of flower seeds made in cooperation with J. L. Anderson and C. L. Thayer, including tests of 172 samples of seed for purity, germination, and performance, are appended.

[Seed and inoculant investigations] (*New York State Sta. Rpt.* 1938, pp. 13, 30, 31).—Brief progress reports are made on the inspection of commercial legume inoculants and seed testing, studies on occurrence of weed seeds and their viability and on hard seed in garden peas, and drill surveys of barley and oats (E. S. R., 80, p. 191).

Chemical soil fumigation for more luxuriant growth and weed control, F. L. HOWARD and F. L. STARK, JR. (R. I. Expt. Sta.). (*Seed World*, 44 (1938), No. 14, pp. 12, 13, figs. 3).—Fumigation of soil by injection of liquid chloropicrin resulted in increased yields of mangels, rutabagas, and millet, and a number of truck crops, and freedom from certain diseases. Treatment of compost soil for top dressing turf has killed weed seeds. Conditions essential to success with this method are described.

Chloropicrin soil fumigation, F. L. HOWARD and F. L. STARK, JR. (R. I. Expt. Sta.). (*Seed World*, 45 (1939), No. 8, pp. 8, 9, 25, 28, figs. 5).—Additional information is given on methods of applying chloropicrin for weed control, etc., and on conditions where soil fumigation is practical.

HORTICULTURE

[Horticultural studies by the California Station] (*California Sta. [Bien.] Rpt.* 1937-38, pp. 9, 10, 21, 22, 23, 24-28, 34, 35, 87-94, 102-104, 110).—Included are reports relating to the comparative yield and quality of plants in water and soil cultures; breeding of onions; development of new tomato varieties; straw-

berry, almond, and grape breeding; development of effective insect-resistant grape rootstocks; testing of blight-resistant pear stocks; influence of rootstocks on lemon yields; causes of premature decline in lemon trees; fertilization of citrus trees; irrigation of fruit and nut trees; pollination of deciduous fruits; thinning of the apricot; pruning wine grapes; development of citrus dusting equipment; improvement of orchard heaters and heating techniques; use of blowers for frost protection; precooling of vegetables and melons prior to long-distance shipments; maturity studies with grapes; temperatures for wine grapes; and gas storage of fruits.

[Horticultural studies by the Delaware Station], L. R. DETLEN, E. W. GREVE, and F. S. LAGASSÉ (*Delaware Sta. Bul.* 214, (1938), pp. 27-29).—Presented are brief progress reports on studies relating to the effect of the removal of the largest fruit from clusters on, and the relation of plum curculio injury to, the physiological dropping of fruits, the normal variation in the growth of apples on seedlings and on own roots, cover crops for apple orchards in Sussex County, and the value of various English rootstocks for Blaxtayman and Gallia Beauty apple trees.

[Horticultural studies by the Florida Station], E. H. HULL, W. A. CARYER, R. W. RUPRECHT, G. H. BLACKMON, R. D. DICKEY, F. S. JAMISON, R. J. WILMOR, A. L. STAHL, J. C. CAIN, J. V. WATKINS, J. H. JEFFERIES, A. F. CAMP, C. R. TOWNSEND, J. R. BECKENBACH, J. R. NELLER, W. T. FORSEY, H. S. WOLFE, and W. M. FIFIELD (*Florida Sta. Rpt.* 1938, pp. 45, 80, 81, 90-98, 100-104, 105, 106, 107, 108, 140, 142-145, 151, 152, 172, 173, 184, 185, 186, 188, 189, 190, pp. 4).—Studies the progress of which is discussed include sweet corn breeding; varieties, culture, fertilizers, and handling of pecans; propagation and culture of tung-oil trees; use of manganese sulfate as a corrective for chlorosis affecting ornamentals; varieties and storage of gladiolus; fertilization of celery and other vegetables; relation of N absorption to food storage, growth, and reproduction in pecans; varieties of fruits and ornamentals; cold storage of citrus fruits; relation of appearance, texture, firmness, and color of citrus fruits to their quality as measured by chemical tests; relation of soil reaction to growth and yield of beans, eggplant, and tomatoes; selection and development of vegetables adapted to Florida; effects of green manure crops on growth, yield, and quality of vegetables; and the effect of certain root-inducing substances on cuttings.

Studies at the Citrus Substation include varieties and breeding of citrus, the effect of mulching and cultivation on growth and yield, and the effect of Mg on the bronzing of citrus trees.

Projects at the Everglades Substation include citrus, tung-oil, and pecan tree trials, fertilizer requirements of vegetables and citrus, testing of varieties of vegetables at different fertility levels, and control of puffiness in the tomato.

Subtropical Substation projects reported relate to citrus and avocado culture, improvement of tomatoes by selection of new hybrids, tomato culture, and vegetable variety trials.

[Horticultural investigations by the South Dakota Station], L. L. DAVIS (*South Dakota Sta. Rpt.* 1938, pp. 34, 36).—Included are brief reports on the breeding of roses, apples, and apricots; genetics of hardy, thornless rose stocks; development of hybrid drought-resistant sweet corn; and the production of sweet, firm-fleshed tomatoes with a minimum of seeds.

[Horticultural studies by the Washington Station], J. L. ST. JOHN, F. VAN AMBURGH, O. M. MORRIS, F. L. OVEREY, J. B. ROBERTS, E. L. OVERMORSE, H. B. WOOTON, J. MARSHALL, O. D. SCHWARTZ, W. J. LOMB, G. A. HUBER, G. L. VINCENT, L. C. WHEETING, S. E. WADSWORTH, O. A. LARSON, and J. C. CROWLEY. (Partly coop. U. S. D. A.). (*Washington Sta. Bul.* 808 (1936), pp. 27, 40, 43, 49,

50, 51-55, 55-59, 79-82, 86, 87, 88, 89).—Brief reports are presented on the following investigations: Characteristics of maturing apples, orchard cover crops, relation of fruit maturity to storage, methods of propagating hardy apple stocks, causes of winter injury to fruit trees, factors affecting the set of fruit in Washington orchards, nature of spray injury to fruit trees, strawberry and raspberry breeding, orchard fertilization and irrigation, selection and breeding of truck crops, fertilizer requirements of vegetables, fruit handling and storage, soil moisture relationships in orchards, varieties of fruits and vegetables, and the fertilization and irrigation of cranberries.

Annual reports of the Canal Zone Experiment Gardens for the fiscal years, 1935 and 1936, J. E. HIGGINS and W. R. LINDSAY (*Canal Zone Expt. Gard., Ann. Rpts., 1935-36, pp. 59, pls. 12*).—These general reports include information on the production of rubber- and insecticide-yielding plants, tropical waterlilies, mangosteens, mangoes, coconuts, citrus, teak, bamboo, and other plants.

[Vegetable crop investigations by the New York State Station (*New York State Sta. Rpt., 1938, pp. 29, 33-35*).—Included are brief reports on the following studies: Breeding mosaic-resistant cucurbits; placement of fertilizers; use of granulated fertilizers; supplementing rye cover crop with fertilizers; use of borax for preventing physiological break-down of beets; testing of new forms of phosphorus, methods of fertilizing to overcome the soil-exhausting effects of beets; breeding of muskmelons, squash, sweet corn, and tomatoes; comparison of southern- and home-grown tomato plants; and the effect of size of Golden Bantam seed on yield, time of maturity, etc.

Varieties for the vegetable garden, H. MATSON (*North Dakota Sta. Bmo. Bul., 1 (1939), No. 4, pp. 15, 16*).—A list of adapted and desirable varieties is presented.

A further report on the storage of vegetable seeds, L. V. BARTON (*Contrib. Boyce Thompson Inst., 10 (1939), No. 2, pp. 205-220, figs. 1*).—Using the same material and methods employed in earlier studies (*B. S. R., 75, p. 46*), the author reports that the viability of lettuce, onion, and cauliflower seeds stored at room temperature may be prolonged markedly by adjusting the moisture contents to from 6 to 8 percent. Favorable results were also secured with tomato, carrot, and eggplant. In the case of pepper, moisture reduction was beneficial, but lowering of the temperature was needed for successful storage beyond 4 yr. Germination tests of old and fresh seeds stored for short periods at various relative humidities and temperatures indicated that with relative humidities of 50 percent or lower the temperature may be as high as 35° C. (95° F.), for seeds with high germination power and the storage period as long as 3 mo. without serious impairment of germination. Above 50-percent relative humidity and storage temperatures of 20° or lower were required. Pretreatment of lettuce seed on a moist medium at 25° or below permitted germination at high temperatures which are ordinarily prohibitive. Pretreated seed may be dried at room temperature for at least 3 days, after which a germination of 50 percent can still be secured at 30° and 25 percent at a temperature of 35°. Vigorous carrot, eggplant, onion, tomato, and lettuce seedlings were secured from 6-year-old seed stored under favorable conditions. A slight initial retardation of growth was noted in cases of unfavorable storage conditions.

Superb Golden, a new hybrid muskmelon, C. H. MAHONEY (*Michigan Sta. Quart. Bul., 21 (1939), No. 3, pp. 225-227, fig. 1*).—In connection with an account of the parentage and development there are presented a description of the fruit and recommendations as to harvesting and handling. Since Honey Dew

was one of the parents, storage for several days at from 70° to 75° F. is needed to increase the sugar content and permit full development of flavor.

The use of the analysis of covariance and its limitation in the adjustment of yields based upon stand irregularities, C. H. MAHONEY and W. D. BATEN. (Mich. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 5, pp. 317-328).—The analysis of covariance between yield of marketable ears and stand of plants is presented for 26 hybrid strains and 1 open-pollinated strain of sweet corn. The yield data for 5 plats were lost, and a method of estimation for these missing plats is given. The correlation coefficient for error exceeds the 1-percent level, and an equation is given by which it is possible to adjust the yields on stand for each of the 108 plats. A short method of deriving an analysis of variance for adjusted yields without the necessity of actually adjusting individual plat yields is presented. That this method is mathematically correct is substantiated by the derivation of essentially identical analyses of variance by both methods. The efficiency was increased by adjusting yields. Another example is presented of corn planted in a 10×10 Latin square in which there was a significant residual correlation between yield and stand. The efficiency of the experiment, however, was not increased by adjustment of yield on stand in this case. In a fertility experiment with tomatoes grown from transplants treatment variance and the correlation coefficient between yield and stand were not significant, yet the efficiency gained in adjusting yield on stand is indicated when the adjusted treatment means are compared with the check (no treatment). Additional data from a fertilizer placement test with Refugee beans, however, showed that the value of *F* for yields was not significant after adjusting for stand.

Influence of moisture and low temperature on the germination of hop seeds, D. C. SMITH. (U. S. D. A. and Oreg. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 5, pp. 369-381).—Of various treatments tested at Corvallis, Oreg., as a means of stimulating the germination of hop seeds, that which provided 5 days' incubation in a standard germination chamber followed by 5 weeks' refrigeration at 5° C. (41° F.) resulted in the highest germination. While germinability was often below 10 percent in untreated lots, percentages as high as 80 were attained in the treated series. Varietal differences in reaction to temperature and moisture treatments were not established. Individual seedling plants varied markedly with respect to the germinability of their seed. No difference attributable to treatment was noted in vigor of the seedlings. Under open field conditions climatic factors are believed to overcome dormancy.

Longevity of onion seed in relation to storage conditions, J. H. BEATTIE and V. R. BOSWELL (U. S. Dept. Agr. Circ. 513 (1939), pp. 23).—Stating that under ordinary handling onion seed is one of the shortest-lived kinds among common vegetables, the authors discuss the results of storage experiments, in part previously noted (E. S. R., 80, p. 484), in which various temperatures, relative humidities, and types of containers were used. Seeds sealed with low moisture content and stored at 20° F. maintained their viability without significant loss over a 9-yr. period. High moisture and temperature were harmful, particularly so when both occurred at the same time. It is recommended that for the maintenance of viability onion seed be reduced to a moisture content of not over 6 percent and stored in sealed containers held at 40° or lower. The superiority of seed of initially high viability was indicated in the fact that such seed held up the best during the tests.

Problems in growing tomatoes in Illinois, W. A. HUELSEN (*Illinois Sta. Circ.* 491 (1939), pp. 48, fig. 1).—General information is presented on ecological conditions influencing tomato growing in Illinois; fertility requirements;

preparation of the soil; raising, handling, and setting plants; cultivation; irrigation; staking and pruning; harvesting and grading; and suitable varieties.

One and a half tons of tomatoes from fertilizer costing 48 cents, C. B. SAYRE (*Farm Res. [New York State Sta.], 5 (1939), No. 2, pp. 1, 5*).—Under comparable conditions as to general field fertilization and management, the application per plant at time of setting in the field of 1 pt. of water in which were dissolved fertilizing materials containing N, P, and K resulted in materially larger early and total yields than were secured with water alone. It is believed that the "starter" solution supplied available nutrients at a critical stage, permitting the plant to quickly reestablish itself and resume vigorous development. P was indicated as the most important nutrient factor.

[Pomological investigations by the New York State Station] (*New York State Sta. Rpt. 1938, pp. 25-27, 28, 29*).—Included are general progress comments on the following studies: Fruit breeding; use of colchicine for producing polyploidy in flowers and fruits; rootstocks for plums and cherries; soil management of orchards; nutrient needs of the strawberry and blueberry; fertilizers for apple orchards in the Hudson River Valley; grape culture, propagation, and pruning at Fredonia; testing of dwarfing rootstocks for the apple; rootstocks for the sweet cherry; developmental morphology of stone and pome fruits; testing of hop varieties; and the breeding of ornamental crab apples.

Some experimental findings of interest to fruit growers, F. L. OVERLEY and E. L. OVERHOLSER. (*Wash. Expt. Sta.*). (*Wash. State Hort. Assoc. Proc., 34 (1938), pp. 113-122*).—This is a general résumé of experimental findings, for the most part previously reported.

Orchard soil management: Some effects of different practices on the soil, N. J. SHAULIS and F. G. MERKLE (*Pennsylvania Sta. Bul. 373 (1939), pp. [2]+26, figs. 5*).—Studies of soil collected from selected orchard blocks under clean cultivation, cover crops, and sod, as well as from nearby fields, forests, and fence rows, indicated that the various systems of management had brought about measurable differences in C, N, and volume weight of the soils. The depth of the topsoil was definitely affected by the method of handling. Sod culture was definitely superior, as far as fertility was concerned, to either clean cultivation or the use of annual cover crops. In fact, the use of sods increased the total N content above that of forest soil. The growing of non-leguminous covers did not maintain the total N, organic C, or volume weight as well as under forest conditions, but did, when properly managed, maintain the orchard soil. The low volume weight and associated high porosity and high permeability of orchard soils was maintained by leguminous covers and by grass sods. Clean cultivation without cover crops was found to be a soil-depleting system attended by large losses of organic C and total N. Clean culture caused great damage to the soil structure in its capacity to retain water. Clean culture must eventually lead to the premature abandonment of the orchard. Sod-forming covers, either permanent or occasionally torn up, are conceded the most satisfactory means of maintaining the fundamental soil qualities that lead to sustained productivity.

Fruit tree response as affected by fertilizer and minor element deficiencies, E. L. OVERHOLSER, F. L. OVERLEY, L. B. WOOTON, and J. B. ROGERS. (*Wash. Expt. Sta.*). (*Wash. State Hort. Assoc. Proc., 34 (1938), pp. 73-87*).—In connection with this analysis of the fruit tree nutrition situation, certain data are incorporated. Where soil samples were collected near fruit trees, 6 ft. distant, and midway between the trees, the soil near the trunk was found slightly more acid than that farther away. Organic-matter content varied with

the soil type and in any one soil tended to decrease with depth. Favorable results were secured from the use of B, either as an injection or as a soil application for the control of cork spot, hard end, and black end of Arzon pears. There was indication that cork spot may be the result of a deficiency of both Cu and B.

The tolerance of various orchard cover crops to arsenical toxicity in the soil, O. M. MORRIS. (*Wash. Expt. Stn.*). (*Wash. State Hort. Indus. Progr.* 34 (1938), pp. 110-112).—In this preliminary report comments are presented on the behavior of various legumes, grasses, grains, and weeds growing in soil with a high arsenic content.

Fertilization of apple and prune orchards in Idaho, L. B. TWISS, (*Idaho Sta. Bul.* 226 (1938), pp. 19).—In experiments extending over a 5-yr. period, no significant benefit to apple trees was observed from the application of N, P, or K, either singly or in combination. Ammonium sulfate applied to Italian prunes in the Boise Valley increased yields an average of 54 percent over a 6-yr. period as compared with adjacent unfertilized trees. The yield increments were accompanied by a material increase in both trunk and twig growth. Applications of 1 lb. per tree were nearly as effective as larger applications up to 6 lb. per tree. In the Payette Valley, ammonium sulfate increased the yields of Italian prunes about 18 percent over the unfertilized checks, but there was no conclusive evidence of benefit from either P, or K, although K may have slightly increased the yields. None of the fertilizer treatments had any apparent effect on the quality of the fruit of either the apple or prune. The author concludes that the use of commercial fertilizers in southern Idaho prune and apple orchards should be restricted to those orchards in which preliminary tests show definite responses.

The water conductivity of the graft union in apple trees, with special reference to Malling rootstock No. IX, L. G. G. WARNE and J. RABY, (*Am. Pomol. and Hort. Sci.*, 16 (1939), No. 4, pp. 380-399).—Observations on the water conductivity of the graft union in a number of apple trees, both single and double-worked, indicated that the union introduces an additional resistance to the flow of water in the trees. This resistance was greatest when the dwarfing stock Malling IX was used. The extent to which the union influences the water economy of the tree could only be conjectured, but certain growth characters of trees on Malling IX stock, namely, small leaves, short internodes, and early cessation of growth extension are characters which might be expected in the presence of inadequate water.

A practicable method of top-working large apple trees, F. C. LEBLANC and H. A. CARDINER, (*Michigan Sta. Quart. Bul.*, 34 (1939), No. 3, pp. 184-191, figs. 7).—Herein is discussed a modified method of dilute grafting which was found effective in top-working apple trees.

The morphology of the apple flower.—II. The use of flower characters in varietal description [trans. title], G. KRUMHOLTZ, (*Gartenbauwissenschaften*, 13 (1939), No. 1, pp. 1-65, figs. 31).—In this second contribution, (p. 48), the author discusses certain flower characters, such as the form of the calyx leaves, relative pistil length, pubescence, and the degree of pubescence of the pistil branches, and the form of the stigma, all of which were found sufficiently distinct to serve as a basis for varietal classification. In fact, floral characters were found as good as, if not better than, leaves and fruits for varietal identification. In triploid apples, the form of the petal was strikingly, if not exclusively, heart-shaped.

Time of picking the Kendall apple, G. H. HOWY, (*Univ. Ark. Agric. Mech. Stat. Sta.*, 5 (1939), No. 2, p. 2, 1).—Observations on Kendall apples harvested at 10-day intervals indicated that greenness of the flesh disappeared

has maturity advanced. The results suggested that care should be exercised not to pick this variety too early. (11) The quantity of ethylene present in apples. B. C. NELSON, (Minn. Expt. Sta. 110) (*Plant Physiology*, 12 (1937), No. 4, pp. 1004-1005, fig. 1). A method for the determination of ethylene in plant tissue is briefly described, and the results of preliminary determinations on the tissue of McIntosh apples are given. Fruits after 9 mo. of storage showed an ethylene content of the order of 0.12 mg. per kilogram of fresh tissue. (12) The determination of ethylene evolved by apples and pears. B. E. CHRISTENSEN, E. HANSEN, V. H. CHELDELIN, and B. C. STARK, (Oreg. State Coll.) (*Science*, 89 (1939), No. 2310, pp. 319-321, figs. 1-3). A method applicable to small lots of fruit is described, and compared with existing procedures. (13) The pollination of the pear on Vancouver Island, British Columbia. B. D. BAIL, (*Sci. Agr.*, 18 (1939), No. 8, pp. 358-371, figs. 4-7). Blooming records presented for fifty odd varieties of pears show that, except for the earliest and latest, there was adequate overlapping to provide opportunity for cross-pollination. A marked degree of self-incompatibility was shown in most varieties, 20 failing to mature any fruit upon selfing. June drop was greater in self than in cross-pollinated fruits. Successful combinations are suggested, with the comment that Bartlett was an effective pollinizer for many other varieties. (14) Studies on pollen tube growth in *Prunus*. B. REX, (*Jour. Pomol. and Hort. Sci.*, 16 (1939), No. 4, pp. 330-338, pl. 1, fig. 1). Treatment of the styles of the self-incompatible Noir de Schmidt cherry with phenylacetic acid had no accelerative effect on pollen tube growth or fruit development. Neither naphthylacetic nor indoleacetic acid had any effect on the setting or development of fruit. In the self-incompatible Coe Golden Drop plum, self-pollination was followed by arrested tube development in the stylar tissue. In cross-pollinations of compatible varieties of plums, some of the pollen tubes failed to reach the ovary and exhibited swollen tips, thus suggesting the presence of two pollen genotypes. In reciprocal crosses between the Victoria plum (*P. domestica*), a hexaploid, and the Pissardi (*P. diguicaria*), a diploid, it was found that the rate of growth of diploid pollen tubes in a hexaploid style is much more rapid than vice versa. (15) Studies on some factors relating to hardiness in the strawberry. (*Minnesota Sta. Tech. Bul.*, 135 (1939), pp. 36, pls. 2, figs. 4). This bulletin is presented in three parts, the first of which, by R. Angelo, deals with the development of cold resistance in strawberry varieties, and indicates that plants dug and potted in November, and then held in a greenhouse at about 20° C. (68° F.) may be hardened by placement in a freezing chamber at 0° to withstand freezing at -10°. After hardening for 10 days at 0° strawberry plants were killed when the temperature reached about -10°. More than 7 days at 0° did not increase hardiness. Although constant exposure at 20° did not harden plants, daily alternation of 12 hr. at 0° and 12 hr. at 20° provided greater hardiness than continuous 0°, provided the 12 hr. at 0° immediately preceded the test. Varieties differed greatly in their hardening capacity. Plants watered abundantly were less hardy than those watered sparingly. Placement of runners in sucrose solution had no evident effect on hardiness. The amount of browning in the medulla was an indication of the degree of freezing injury. (16) Bartlett by V. R. Iverson, on winter soil temperature as a factor in the environment of the strawberry and some other herbaceous plants, records the temperature of the air, and of the soil at different depths, under various types of ground covers. It was found that the physical state of the cover is more

important than the material itself. For example, when peat became wet, packed, and frozen, it lost most of its effectiveness. Of several mulches tested, one consisting of mixed leaves appeared most effective because it was least affected by physical conditions. Whereas loose snow proved an excellent protection, ice had little value, and when present in organic materials greatly reduced their effectiveness. Beneath ice, soil temperatures attained a temperature below the safety point for strawberries.

Part 3, by W. G. Brierley and R. H. Landon, on the respiratory rate of dormant strawberry plants, was presented in condensed form in an earlier paper (E. S. R., 80, p. 346).

The relative importance of various factors influencing profits in strawberry production, N. D. PEACOCK (*Michigan Sta. Tech. Bul. 162 (1939), pp. 75*).—Based on an analysis of production records obtained from commercial growers and upon correlated field trials, the conclusion is drawn that profits depend upon three general factors, namely, cost of production, yields per acre, and selling prices. In the first bearing season, cost of production represents nearly half the total cost. In the second season, harvesting and handling the crop accounted for three-fourths of the outlay. The various items of the producing costs are evaluated. Strawberry yields were found dependent upon several factors, none of which was predominant under all conditions. Character of the soil was of primary importance in most cases, with a sandy or gravelly loam in good physical condition considered ideal. Cultivation was highly important, especially during the first growing season. Fertilizers proved of doubtful value on good soils and in such instances may fail to return a profit. Stand of plants in the matted row was found one of the most important factors effecting yields, with total production increasing until eight or nine plants per square foot were reached. Beyond that point total yields and proportion of large fruits may decline. Under the conditions of the test, five or six plants per square foot produced the most profitable yields. The relation of climate to strawberry growing is discussed.

Handling and shipping strawberries without refrigeration, D. F. FISHER and J. M. LUTZ (*U. S. Dept. Agr. Circ. 515 (1939), pp. 16, figs. 9*).—Based on studies of Maryland and North Carolina strawberries shipped by motor truck and express without refrigeration, it was found that timing and care in picking were important factors in relation to shipping quality. Harvesting in the early morning and at frequent intervals, generally at least every other day, was found desirable. Careful picking, which included clean picking and the selection of berries before they reached the full-ripe stage, favored successful shipment. Picking care that eliminated the need of repacking was helpful. Facing the berries or the use of cellophane covers had no apparent benefit on shipping quality but did give a better appearing product. The amount of decay was closely correlated with temperature, especially when above 40° F. The redesign of shipping crates to cause less crushing and cutting of the berries is recommended.

The effect of lead arsenate and copper carbonate sprays on the quality of oranges, R. H. MARLOTH and F. J. STOFFBERG (*Jour. Pomol. and Hort. Sci., 16 (1939), No. 4, pp. 329-345, fig. 1*).—Lead arsenate applied at the rate of 1 oz. per large Washington Navel orange tree caused a slight increase in the soluble solids: acid ratio in the juice of the fruit. At the rate of 5 oz. per tree, there was a marked reduction in acid. There was a residual effect on the succeeding two crops. In fact, the reduction in acid was greater in the first succeeding crop than in the year of application. Arsenate of lead had no noticeable effect on the total soluble solids in the juice, and the arsenic content of

the juice of lead arsenate sprayed fruits was negligible. Copper carbonate produced no effect on either the total soluble solids or the acid content of the juice but did accelerate coloring slightly. There was no increase in lead or copper in the juice of the sprayed fruits.

A new palm from Costa Rica, *Astrocaryum alatum*, H. F. LOOMIS. (U. S. D. A.). (*Jour. Wash. Acad. Sci.*, 29 (1939), No. 4, pp. 141-146, figs. 2).—*A. alatum* n. sp. is described. Though too soon to be certain it will survive and become a part of Florida's subtropical horticulture, it is deemed promising.

The horticultural hibiscus in Ceylon, T. H. PARSONS (*Ceylon Dept. Agr. Bul.* 93 (1938), pp. 6, pls. 5).—Brief descriptive accounts accompanied by colored illustrations are presented.

The garden of larkspurs, L. H. BAILEY (*New York: Macmillan Co.*, 1939, pp. VIII+116, pls. 25).—This includes general information on culture, breeding, and botany. The chapter on diseases was prepared by L. H. Leonian of the West Virginia Experiment Station and that on insects by W. E. Blauvelt of Cornell University.

Notes on orchid cultivation and on some orchids cultivated in Ceylon (*Ceylon Dept. Agr. Bul.* 94 (1938), pp. [1]+35, pls. 35).—Information is offered as to culture and varieties.

Germination and growth of some rock garden plants, E. M. SCHROEDER and L. V. BARTON (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 2, pp. 235-255).—The results of studies with seeds of 17 species of plants are discussed. Light was shown in certain species to exert a profound effect on germination. *Primula obconica* and *Ranondia pyrenaica* seeds required light for germination, and in the case of 4 other species exposure to light permitted germination at temperatures ordinarily prohibitive.

FORESTRY

Shelterbelts: The advantages of porous soils for trees, J. H. STOECKELER and C. G. BATES. (U. S. D. A.). (*Jour. Forestry*, 37 (1939), No. 3, pp. 205-221, figs. 4).—Moisture determinations of soil samples collected in western Oklahoma in June and July 1935 to a depth of 8 ft. from beneath various covers, such as native grass, scrub oak, and cultivated crops, showed a generally greater amount of free water in the loamy sand and sandy loam than in the finer soil types. The amount of the total water in the fine-textured soils was higher but was less available because of the relatively high hygroscopic coefficients. There was less free water in grassland and under trees than in most croplands. Fallow land showed the highest average amount of free water. Storage of moisture occurred in larger measure and at a greater depth in the sandy soils than in the fine-textured soils.

Storage of elm seeds, L. V. BARTON (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 2, pp. 221-233, figs. 3).—Elm seeds germinated well in moist granulated peat moss at controlled constant temperatures of 15°, 20°, and 25° C., or at daily alternating temperatures of from 10° to 20°, 10° to 25°, 10° to 30°, and from 15° to 30°. For germination in soil in the greenhouse, presoaking in water for 24 hr., as well as pretreatment in moist granulated peat moss at 5° for 1 mo., greatly increased germination. Seeds of a moisture content of 7 percent were superior in viability to those of 8-percent content after storage in sealed containers at room temperatures. An atmosphere of oxygen proved especially harmful when both moisture content and storage temperature were relatively high. A vacuum served to prolong viability when other storage conditions were unfavorable. Elm seeds were kept viable for at least 16 mo. when held in sealed containers kept at 5° or below.

The production of certified holly in Maryland. N. H. FRETZ (*Jour. Forestry*, 37 (1939), No. 3, pp. 236-238, fig. 1).—A method of cutting is described in which the tree is carefully pruned so that crops may be secured every other year without ruining the tree.

Persistence of stems per sprout clump in oak coppice stands of southern New Jersey. O. M. WOOD. (U. S. D. A.). (*Jour. Forestry*, 37 (1939), No. 3, pp. 269, 270).—Despite the fact that of several species post-oak had the greatest relative number of one-stem clumps, its low growth rate of this advantage. On the other hand, the rapid growth rate of scarlet oak rendered it a potentially valuable species despite its tendency to develop a large number of stems per clump.

The growth and nutrition of white pine (*Pinus strobus* L.) seedlings in cultures with varying nitrogen, phosphorus, potassium, and calcium, with observations on the relation of seed weight to seedling yield. H. L. MITCHELL (*Black Rock Forest Bul.* 9 (1939), pp. 41-135, pls. 4, figs. 123-22). Plants grown from seed taken from a single tree and cultured for 200 days in sand, the N, P, K, and Ca contents of which were varied individually, showed under the conditions of the experiment that seedling dry weights were proportional to individual variations in the external supplies of the four elements. In each case a maximum was reached, beyond which further increases resulted in decrements. The responses of seedlings were greater to N, particularly to K and Ca, than to equal increments of P. The root:shoot ratios of the seedlings in the N series tended to vary inversely as the N supply over the greater part of the range studied. Seedlings grown in properly balanced nutrient-sand cultures were far superior, as regards total weight, balance between root and shoot, and, to a lesser degree, root development, than the average nursery-grown seedling of the same age. Results of chemical analyses revealed an exceedingly high correlation between internal content of the four elements and the concentration of the respective elements in the solution. For each element there was indicated an optimum internal concentration through which the seedlings approached or attained maximum growth. It is suggested that the ideal nutrient environment is one so adjusted as to maintain within the seedling a constant and approximately optimal internal concentration. The necessity of using seed of similar initial weight in such critical studies was indicated.

The relationships between cumulative solar radiation and the dry weight increase of nursery-grown white pine and red pine seedlings. H. L. MITCHELL, and R. O. ROSENDAHL (*Black Rock Forest Papers*, 1 (1939), No. 13, pp. 87-93, figs. 2).—In 1936 red pine and white pine seedlings were exposed to radiation intensities of 30, 57, 78, and 100 percent of full sunlight secured by means of brass wire cloth screens of different transmission capacities. The total yields (roots and shoots) increased with increasing solar radiation over the total range employed. It was evident that response to increments above 50 percent of full sunlight was less than to increments below this point. Evidence is presented that the root:shoot ratios and the yields of seedlings grown in different years in the same locality may be influenced by climatic factors which change the quality of solar radiation by altering the ratio of infrared to visible radiation. Seedlings grown during a sunny summer in a soil of high fertility may actually be smaller than those grown during a relatively cloudy summer in a soil of lower fertility.

Development of branches and knots in western white pine. E. F. R. BAEGER. (U. S. D. A.). (*Jour. Forestry*, 37 (1939), No. 3, pp. 239-243, figs. 5).—Sections obtained by sawing the portion of the tree between the ground line and the live crown were carefully examined as to the character and habit of

growth of the branches and resulting knots. Branches originated at the pith, and their length of life was strongly influenced by light conditions. Branches higher up on the tree tended to be larger because of their longer life. After death, branches persisted for many years—so long that the author believes that very little clear lumber can be produced naturally unless the rotations exceed 120 yr. The possibility of pruning dead and useless lower limbs to hasten maturation is discussed.

Profitable utilization of white-pine thinnings, W. C. SECORIST (*Jour. Forestry*, 37 (1939), No. 3, pp. 232-235).—Stating that in the State and privately owned forests of Pennsylvania there are many acres of pine plantations in need of thinning, the author discusses the results of a thinning project in the Mont Alto State Forest in which an attempt was made to utilize profitably trees from 6 to 9 in diameter for shingles and boxboards.

Pine in the diet of white-tailed deer, S. E. ALDOUS. (U. S. D. A.). (*Jour. Forestry*, 37 (1939), No. 3, pp. 265-267, figs. 2).—Observations in the Superior National Forest, Minn., showed that although all native species of pine are browsed in the fall months, jack pine is preferred at that season. Few trees were killed by browsing but many were much deformed and retarded. Because of the increasing importance of jack pine as a source of wood pulp, deer injury becomes a matter of significance to foresters.

Turrey pine, L. O. HUNT. (U. S. D. A.). (*Jour. Forestry*, 37 (1939), No. 3, pp. 267, 268).—There were found to be from 416 to 512 seeds per pound, containing approximately 70 percent of sound seed. Turrey pine is said to grow well under adverse moisture conditions but probably does not possess resistance to frost.

The anatomy of spruce needles, H. F. MARCO. (U. S. D. A.). (*Jour. Agr. Research*, 58 (1939), No. 5, pp. 357-368, pls. 17).—Studies of cross and longitudinal sections of *Picea* spp. needles revealed new anatomical features not heretofore recognized. Epidermal cells were found to be equipped with teeth projecting into the cuticle and locked to one another by a modified dovetailed joint. Since trichiform hypodermal fibers overlap, the variation in the size of the bundle is considered of diagnostic value. The thickened upper and lower guard-cell walls near the stomata were separated by two extremely thin, flexible membranes which collapsed when the stomata were opened, bringing the two guard-cell walls in contact. With none, one, or two resin ducts or cysts in any given spruce needle cross section, their number is not of diagnostic value but their diameters are constant within certain limits and may be used in identification. The number of strengthening or fibrous cells adjacent to the bundles is deemed an important distinguishing characteristic. Detailed anatomical descriptions are given for mesophyll, endodermal, and transfusion cells and for fibrovascular bundles. The function of all tissues is also described.

Ohio Forest News, [March 1939] (*Ohio Forest News* [Ohio Sta.], No. 35 (1939), pp. 1-3, figs. 2).—This pamphlet of general information (E. S. R., 70, p. 1932) includes articles on handling of forest products from a catalpa plantation and the silvicultural and marketing requirements of ash.

DISEASES OF PLANTS

The Plant Disease Reporter, April 1 and 15, 1939 (U. S. Dept. Agr., Bur. Plant Indus., *Plant Disease Rptr.*, 23 (1939), Nos. 6, pp. 91-114, figs. 6; 7, pp. 115-128, figs. 2).—The following items are included:
No. 6.—Dutch elm disease in the United States, 1930 to 1938, (with maps); the disease of pines, caused by *Sphaeropsis ellisi*, by A. M. Waterman; tuber diagnosis of bacterial ring rot of potatoes, by J. G. Leach; maturity of asco-

spores of the apple scab fungus; some reports on the early appearance of leaf rust and powdery mildew of wheat and barley, and the overwintering of leaf rust in southern and central Plains States; notes on clover plants affected by stem rot (*Sclerotinia trifoliorum*) and sweetpotatoes, tobacco, and clovers infested by root knot nematodes (*Heterodera marioni*) in Virginia; fifth experimental forecast (for 1939) of the incidence of bacterial wilt of sweet corn, by N. E. Stevens and C. M. Haenseler; the occurrence in an Ohio glasshouse-grown crop of tomatoes of a disease thought to be Australian "spotted wilt," by L. J. Alexander and S. P. Doolittle; occurrence of curly top in the Pacific Northwest in 1938, by B. F. Dana; and further reports on tobacco downy mildew for North Carolina, South Carolina, and Georgia.

No. 7.—New records of *Elsinoe* and *Sphaeceloma* species in the United States, by A. E. Jenkins; hop anthracnose, by G. R. Hoerner; bacterial ring rot of potatoes in California, by P. A. Ark; northwestern anthracnose of apple reported from Massachusetts, by O. C. Boyd; pine tip dieback in Nebraska, by F. R. Lancaster; and brief notes on wheat diseases in Oklahoma, apple scab in New York, and cedar rusts in Oklahoma.

Abstracts of papers [on plant diseases] (*Northwest Assoc. Hort., Ent., and Plant Path., Moscow, Idaho, 4 (1938). Abs. Papers, pp. 1-3, 5, 6, 13-15*).—The following are of interest to phytopathology: The Response of Fruit Trees in Washington to Certain Minor Elements, by E. L. Overholser (Wash. Expt. Sta.); The Boron Deficiency Symptoms on Agricultural Plants in British Columbia, by H. R. McLarty and R. E. Fitzpatrick; A Method of Detecting Boron-Deficient Soils and the Occurrence of Such Deficiencies in Idaho, by W. E. Colwell (Idaho); Zinc Treatments for Little Leaf, by O. T. McWhorter, and Pea Seed Treatments in Relation to Germination, by A. G. B. Bouquet (both Oreg.); Control of Snapdragon Rust, by W. R. Foster; Development of Curly Top Resistance in Beans, by D. M. Murphy (Idaho); Wood Decay of Crowns and Roots of Raspberry Plants, by W. Jones; Blister Rust Control in the Inland Empire, by H. E. Swanson, and Comparative Study of the Apple-Tree Anthracnose and Perennial-Canker Fungi, by J. R. Kienholz (both U. S. D. A.); and The Fruit Disease Situation in Idaho, by E. C. Blodgett (Idaho).

[Plant disease studies by the California Station] (*California Sta. [Buen.] Rpt. 1937-38, pp. 16, 20, 21, 22, 23, 24, 33, 34, 35-47, fig. 1*).—Brief reports of progress are given on studies relating to protection against a new soil-borne variety of wheat smut in the West; development of onion strains resistant to downy mildew and to pink root; breeding peaches resistant to mosaic and to delayed foliation; boron injury to deciduous fruit trees, including plum, apricot, peach, pear, almond, and walnut; prune dieback; psorosis (virus) of citrus trees; granulation of Valencia oranges; control of citrus fruit rots and molds by sprays, washes, and sanitation; water spot of citrus; problems in avocado culture, including the relation of chlorine to ring-neck and to defoliation and severe tipburn; the spread of date decline due to *Omphalia* spp.; control of date spoilage and of fig smut and mold; California vine disease (virus?) and red leaf of grapes (possible control by selenium sprays); bacterial canker of stone-fruit trees; Kelsey spot of plums; chilling requirements for satisfactory opening of deciduous-fruit tree buds and the relation of warm winters to shedding of unswollen fruit buds; soil injections of CS₂ for oak root fungus; control of brown rot blossom blight of stone fruits by eradicant sprays; control of carrot blight (*Cercospora* and *Macrosporium*); spraying for onion mildew; tomato bacterial canker; controlling hop mildew; new information on flower diseases, including bacterial bud rot and blight of lark-

spur, snapdragon rust, *Phoma* stem canker of gardenias, and bacterial blight of garden stock; control of southern root rot of beets; and sugar beet seed treatment for damping-off (*Pythium*, *Rhizoctonia*, and *Phoma*).

Department of plant pathology (*Delaware Sta. Bul. 214* (1938), pp. 29-45, figs. 3).—Reports of progress are given on studies of the dissemination of peach yellows and little peach and factors in their control, by T. F. Manns; control of sweetpotato wilt (*Fusarium batatas*) by chemical treatments, by Manns and J. W. Heuberger; breeding and selection of tomatoes resistant to disease, and tomato foot rot (black shank, collar rot, and early blight due to *Macrosporium solani*), both by Manns; spray materials and dusting work on apple, by Manns, J. F. Adams, and Heuberger; bacterial spot of stone fruits, by Manns, Heuberger, and S. L. Hopperstead; plant disease surveys, by Manns; spray injury, by K. J. Kadow and M. W. Goodwin; tests of new spray materials and dusts, by Kadow and Hopperstead; and cucurbit scab or pox (*Cladosporium cucumerinum*), and control of tomato early blight (*M. solani*), both by Kadow.

[**Phytopathological studies by the Florida Station**] (*Florida Sta. Rpt. 1938*, pp. 74, 75, 80, 83, 109-127, 128, 137-140, 145, 146, 147, 148, 163-169, 175, 176, 181, 182, 185, 186, 190-193, figs. 3).—Brief reports are presented by various station and substation workers (R. M. Barnette, R. W. Ruprecht, H. E. Bratley, A. N. Brooks, A. F. Camp, A. H. Eddins, B. R. Fudge, C. C. Goff, L. O. Gratz, D. G. A. Kelbert, R. H. Kincaid, W. A. Kuntz, K. W. Loucks, W. Reuther, A. S. Rhoads, G. D. Ruehle, W. B. Shippy, W. B. Tisdale, G. R. Townsend, R. K. Voorhees, M. N. Walker, J. R. Watson, G. F. Weber, and E. West) on the following studies: "Chlorosis" in corn and other field crop plants; blackheart of celery; root knot; disease control in potatoes, including bacterial wilt and soft rot, net-necrosis and leaf roll, rugose mosaic, scab, and seedling cross and variety tests in relation to disease resistance and local adaptability; control of brown rot (*Bacterium* (= *Phytophthora*) *solanacearum*) of potatoes and closely related crops; comparison of *Diplodia* forms resembling *D. frumenti*; study and control of *Fusarium nivum* wilt and other diseases of watermelons; control of *Fusarium lycopersici* wilt of tomatoes in Florida; *Clitocybe tubescens* and other root rot fungi of citrus and other woody plants in Florida; factors in the decay of citrus fruits; a bark disease of Tahiti lime trees; fruit rots of grapes; host relations and factors influencing the growth and parasitism of *Sclerotium rolfsii*, a hitherto unreported disease—web blight (*Rhizoctonia microsclerotia*?)—of beans in Florida; the comparative pathogenicity and taxonomy of species of *Alternaria*, *Macrosporium*, and *Stemphylium*; control of *Rhizoctonia* disease of potatoes and vegetable crops; *Sclerotinia sclerotiorum* pink rot of celery; control of pink rot and early blight of celery; gummosis and psorosis of citrus trees; witches'-broom disease of oleander; downy mildew-resistant cucumber and cantaloup for Florida; palm diseases on Key West; relation of fungi and environal factors to failure of centipede grass; control demonstrations with tobacco downy mildew; citrus dieback; citrus scab and its control; melanose and stem-end rots of citrus fruits; the effect of zinc, manganese, and other unusual mineral supplements (Mn, Mg, Cu) on the growth of citrus; seed- and soil-borne diseases of vegetable crops, including seed-piece decay, mosaic, and scab of potatoes, halo blight of beans, seed decay in lima beans, seed and seedling rots of peas, root and stem rots of beans, and damping-off of celery seedlings; and leaf blights of vegetable crops, including bean rust, bean spraying and dusting tests, early blight of celery, lima bean spraying and dusting with special reference to copper injury to the foliage following insect injury, pea spraying and dusting,

downy mildew of peas, early and late blights of potatoes, and nailhead leaf spot of tomatoes; field and laboratory studies of tobacco diseases; algal leaf spot (*Cephaleuros*) of guava and *Alternaria* blight of *Dioscorea carolinensis*; control of potato diseases in Dade County, including early blight, scab, and *Rhizoctonia*, and spindling sprout; diseases of avocados and mangoes and development of control measures, and control of tomato diseases by spraying.

[Phytopathology at the New York State Station] (*New York State Sta. Rpt. 1938*, pp. 22-24, 32).—Progress reports are given on fruit disease investigations, including the control of apple scab, cherry leaf spot, and raspberry mosaic and spur blight; control of cabbage yellows by resistant varieties; *Fusarium* diseases of plants; red copper oxide as a foliage fungicide and its use in controlling various diseases, including damping-off of peas; hop downy mildew control by copper and zinc sprays; seed treatment of potatoes with yellow oxide of mercury for scab; breeding cauliflower resistant to black rot; the cause of poor stands of lima beans on Long Island; and seed-borne microorganisms and their control, including those affecting pea, bean, corn, barley, oats, and celery, and trials of various seed protectants (mercuric chloride and ethyl mercuric phosphate proving efficient).

[Phytopathology at the Washington Station]. (Partly coop. U. S. D. A.) (*Washington Sta. Bul. 368* (1938), pp. 12-14, 55, 59-67).—Brief reports are given on current work relating to the resistance of wheat to bunt and other diseases and inheritance in cereals, by E. F. Gaines, O. A. Vogel, and K. Wade; bitter pit and related diseases of pears, by F. L. Overholser, E. L. Overley, J. B. Rogers, and L. B. Wooten; wheat smut and oat smuts, both by C. S. Holton, F. D. Heald, and Gaines; etiology and control of apple rots; and etiology and prevention of alfalfa failures, both by Heald and R. Wellman; pear rots, by Heald and H. English; forage grass diseases, by G. W. Fischer; etiology and control of sugar beet diseases, including black foot, crown rot, and a root disease, and bean rust, both by L. Campbell; virus and other diseases of potato and other solanaceous plants, by L. K. Jones; virus diseases of peas, by Jones and F. Johnson; diseases of glasshouse plants, including geranium and carnation, and virus diseases of brambles, both by Jones; downy and powdery mildews of peas, by Jones and Campbell; and a summary of a plant disease survey for the season, by Heald, Jones, and G. A. Huber.

Proposed additions to etiological terminology, J. ENGLISH (Univ. Idaho). (*Phytopathology*, 29 (1939), No. 5, pp. 459, 460).—The author proposes the terms "saprogen," "saprogenic," and "saprogenicity," referring particularly to wood decay.

The nomenclature of plant viruses, C. W. BROWN. (U. S. D. A.) (*Phytopathology*, 29 (1939), No. 5, pp. 422-430).—This is a general discussion of classification methods and nomenclatorial systems proposed for use with plant viruses.

Proposal for extension of the binomial system of nomenclature to include viruses, F. O. HOLMES (*Phytopathology*, 29 (1939), No. 5, pp. 431-436).—The desirability of a Latin binomial system for viruses to replace the current numerical systems is discussed, together with an illustrative classification of the plant viruses.

Some recent work on plant viruses, F. O. BAWDEN (*Empire Jour. Exptl. Agr.*, 7 (1939), No. 25, pp. 1-10).—A critical review on the nature of viruses, symptoms of virus diseases, vectors, control, viruses as antigens, and chemical nature and isolation.

Causes of virus diseases in plants; M. T. Cook. (P. R. Col. Expt. Sta.). (Sci. Mo., 48 (1939), No. 4, pp. 357-361).—This is a brief review of theories as to the nature of the viruses causing plant diseases, from the time of Mayer's early publication (1882) on tobacco mosaic to the present time.

Chemistry of the plant viruses; A. S. McFARLANE (Biol. Rev. Cambridge Phil. Soc., 14 (1939), No. 2, pp. 225-242, figs. 8).—This is a critical review.

A note on some protein constituents of normal tobacco and tomato leaves, F. C. BAWDEN and N. W. PRIE (Brit. Jour. Expt. Path., 19 (1938), No. 4, pp. 264-267).—This note deals with the unstable proteins of normal plants, some with molecular weights of the same order as the viruses, which must be removed during the isolation of the viruses.

A list of plant viroses observed in China, T. F. YU (Phytopathology, 29 (1939), No. 5, pp. 460-462).—This is an annotated list of virus diseases observed on 55 economic plant species.

A survey of interaction between fungi; H. R. X. D'ARCY (Biol. Rev. Cambridge Phil. Soc., 14 (1939), No. 2, pp. 105-131).—The literature on interactions among fungi is dispersed and fragmentary, and the author here attempts to survey as far as possible the scattered published results, interactions in the soil, on or in the host plant, and on culture media being considered. The bibliography contains about three pages of references.

A review and extension of our knowledge of *Calyptospora goeppertiana* Kuehn, J. H. RATTL (Jour. Arnold Arboretum, 20 (1939), No. 2, pp. 104-115).—Added to the review of this rust, including its nomenclature and taxonomy are the results of life history studies and lists of 13 species of *Abies* definitely proved to be hosts of the haploid phase and of 7 species of *Vaccinium* definitely proved and 10 species suspected as hosts of the diploid phase. Knowledge of the geographical distribution of the fungus is extended.

The genera *Skierka* and *Ctenoderma*; E. B. MANS (Mycologia, 51 (1939), No. 2, pp. 475-496, figs. 14).—This is a taxonomic study of these two genera of rust fungi (Puccinaceae), in which four new species of *Skierka* are described. There are 20 literature references.

A bacterium antagonistic to *Phytophthora solani*, T. C. GORDON and C. M. HAENSELER (N. J. Expt. Stas.) (Soil Sci., 47 (1939), No. 5, pp. 207-214, pl. 1).—A rough strain identified as *Bacillus simplex* produced a diffusible, heat-stable substance in media which was growth-inhibitory or lethal to *P. solani*. The toxic principle was adsorbed by activated charcoal and could be partially removed from the latter by hot alcohol. Removal by precipitation with alcohol or (NH₄)₂SO₄ of the major portion of the protein fraction from media made toxic to *P. solani* by the bacterium failed to remove or destroy the toxic principle. Treatment of greenhouse soil infested with the fungus by a potato-dextrose-peptone solution used for growing the bacterium or with living, washed bacterial cells without nutrient medium gave appreciable control of seed decay and damping-off in cucumbers and peas, but the sterile medium alone also gave some control, possibly by favoring saprophytic micro-organisms in the soil. The results of the soil tests were thus not so outstanding as those obtained in the laboratory, but there were indications that the organism used was able to produce under soil conditions a material toxic to this fungus.

New species of Uredinales; G. B. CUMMINS (Ind. Expt. Sta.). (Mycologia, 51 (1939), No. 2, pp. 769-774, figs. 5).—The author describes three new species of *Puccinia*, one of *Uromyces*, and two of *Uromyces*. A key based on this study gives the differential characters for species of *Uromyces* on Lorantheae.

Journal of the American Phytopathological Society, Vol. 29, No. 2, 1939, pp. 223-224. Published by the American Phytopathological Society, 1939.

Soil-borne fungi and the control of root disease, S. D. GARRETT (*Imp. Bur. Soil Sci. [Harpenden], Tech. Commun. 38 (1939), pp. 54*).—This monograph (with a bibliography of over seven pages) considers the role of fungi in the soil, plant sanitation by disposal of infected material and by preventing dispersal of the fungus, elimination of infectious material from the soil (by fungicides, mechanical methods, crop rotation, and biological control), adjustment of soil conditions to check the activity of the parasite, and augmentation of host resistance.

The problem of immunity in plants [trans. title], P. NOBÉCOURT (*Bul. Assoc. Dipl. Microbiol. Faculté Pharm. Nancy, No. 17 (1938), pp. 9-28*).—This is a general summary of the present state of knowledge on natural and acquired immunity.

Disease, damage, and pollination types in "grains," N. E. STEVENS. (Univ. Ill.). (*Science. 89 (1939), No. 2311, pp. 339, 340*).—The author examines the available evidence as to whether genetic uniformity will or will not favor the building up of specialized strains of parasites. In doing so he develops a "disease index" based on the volume of the literature and the economic value of the specific crop plants concerned. He concludes: "Any one who is unwilling to accept the significance of a correlation between the striking freedom from disease and the fact that the plant can reproduce only by crossing . . . should at least advance some other hypothesis."

The relation of copper fungicides to lead arsenate-lime and fixed nicotine-oil sprays—1938 results, K. J. KADOW, S. L. HOPPERSTEAD, and M. W. GOODWIN. (Univ. Del.). (*Peninsula Hort. Soc. [Del.] Trans., 52 (1938), pp. 88-98, fig. 1*).—All the insoluble coppers used with lead arsenate induced less fruit injury and copper leaf burn than bordeaux mixture, but they stuck very poorly to apple fruit and leaves, except for copper phosphate-lime-bentonite which failed in controlling bitter rot and codling moth. This result appears to show that too much inert matter may reduce the value of some sprays. All of the insoluble coppers used with lead arsenate proved inferior to bordeaux in controlling arsenical injury, but a few were commercially satisfactory, viz, oxo-bordeaux, cupro K, copper hydro, and compound A.

None of the coppers could be safely used in Delaware with fixed nicotine and oil without lime, though it is possible that nicotine sprays might be used with lime, and therefore with some of the coppers, if the interval between sprays were shortened. Fixed nicotine greatly increased the solubility of the insoluble coppers (laboratory analyses). All copper fungicides used increased the release of nicotine over that in regular fixed nicotine-oil sprays and seemed also to reduce the original nicotine deposits although the nicotine-oil sprays actually increased the copper residues over the lead-lime series. The pH values of the various copper fungicides alone in water varied greatly in different batches and were not always correlated with actual nicotine release in the field.

It is concluded that "bordeaux still remains the most satisfactory fungicide; one of the most suitable materials for the correction of arsenical injury and one of our few reliable stickers."

Soil fumigation with chemicals, F. L. HOWARD. (R. I. Expt. Sta.). (*Market Growers Jour., 64 (1939), No. 6, p. 141, figs. 2*).—Successful results are reported on the use of chloropicrin for soil fumigation against fungus and insect pests and weeds, including 2 years' tests with tomatoes, peppers, eggplants, onions, potatoes, mangels, rutabagas, cabbage, buckwheat, corn, millet, and carrots.

New use for World War tear gas: Sterilization of soil and nematode control offers peace time use for chloropicrin, G. H. GODFREY. (Tex. Expt. Sta.). (*South. Seedsman, 2 (1939), No. 2, pp. 3, 14, 20, fig. 1*).—This is a semi-popular account summarizing the results of studies by the author (E. S. R., 75,

p. 638) and others leading to successful control of insects in stored products, of nematodes, and of soil fungi and insects by the use of chloropicrin.

Seed certification in Germany [trans. title], K. SNELL (*Chron. Bot.*, 5 (1939), No. 1, pp. 53, 54).—This is a discussion of the legal regulation adopted in Germany whereby only certified seed (tested for variety, purity, and condition in respect to disease) is to be allowed in commerce. Certification is to be granted on the basis of field inspection of the plants and also in many cases of further testing of the seed ready for sale. The number of varieties is to be restricted to those considered most desirable. New varieties are to be substituted for less desirable varieties on the governmental variety list only after tests for yield, quality, and disease resistance at scientific institutes. Beginning in 1941 only varieties of potatoes immune to potato wart disease will be permitted to be grown. Only immune varieties may now be certified for seed purposes. The earlier studies were carried out with respect to grain varieties, and not until recent years were other kinds of agricultural plants included.

Seed treatments for cereal crops, W. E. BRENTZEL (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 4, pp. 17–20, figs. 2).—Directions are given for seed disinfection for the control of seed-borne diseases of wheat, oats, barley, rye, emmer, millet, and corn. The organic mercury dusts are recommended for covered smut and certain blights of wheat, covered smut and stripe of barley, and smuts of oats and millet and covered smut of emmer; and the copper carbonates and basic copper sulfate for covered smut of wheat only.

Recent developments and future trends in cereal-seed treatment, R. J. HASKELL (*U. S. Dept. Agr., Ext. Path. No. 37* (1939), pp. 41–45).—A summary of recent investigations, with nine references.

Memoir on the immediate cause of bunt or smut of wheat, and of several other diseases of plants, and on preventives of bunt, B. PRÉVOST, trans. by G. W. KEITT (*Phytopath. Classics No. 6* (1939), pp. 95, pls. 3).—A foreword, biographical sketch, and evaluation of this historically significant memoir by the translator precedes the text, the original of which has "been followed as closely as seemed consistent with rendition in acceptable English."

A chlorotic mottling of wheat leaves caused by infections of bunt *Tilletia laevis*, C. O. JOHNSTON and C. L. LEFFBURE. (Kans. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 5, pp. 456–458, fig. 1).—In greenhouse tests bunted wheat (both spring and winter) almost invariably exhibited a yellowish mottling of the leaves, while noninfected plants remained a normal green. By this mottling infected plants could be identified long before heading, but owing to complicating factors the presence of mottling in the field was not as certain an indication.

Results from the uniform bunt nurseries in the western region in 1938, with averages for 1937, C. S. HOLTON and C. A. SUNESON (*U. S. Dept. Agr., Bur. Plant Indus.*, 1939, pp. 3).—Seeds were sown in uniform nurseries at 10 locations (1938) to determine the reactions of 27 winter wheat varieties to bunt, other than the "dwarf" race of *Tilletia tritici*, and the data obtained are summarized in two accompanying tables and discussed.

[**Leaf and stem rust of wheat**], C. O. JOHNSTON (*In Report of the Fourth Hard Red Winter Wheat Improvement Conference. Manhattan, Kans., 1938, pp. 8–14*).—This is a progress report on breeding of wheat for leaf rust resistance, with lists of varieties or named hybrids and promising unnamed hybrids deemed to be the best sources of resistance; and a summary of the reactions of commercial varieties of winter wheat to stem rust (resistant, moderately resistant or tolerant, rust escaping, and susceptible), with a list of hybrid selections having strong resistance.

Revised register of physiologic races of leaf rust of wheat (*Puccinia triticina*), H. B. HUMPHREY, C. O. JOHNSTON, R. M. CALDWELL, and L. E. COMPTON. (Coop. Ind. Expt. Sta.). (*U. S. Dept. Agr., Bur. Plant Indus., 1939, pp. [1]-18*).—This revision (*E. S. R., 77, p. 346*) includes all additions and brings the number of recognized races to 105. Tables indicate the reactions of differential varieties of *Triticum vulgare* to these races, and present information on original descriptions and place and year of discovery or report. An analytical key for identification of the races is based on their parasitic behavior on wheat varieties.

Studies on *Polymyxa graminis*, n. gen. n. sp., a plasmodiophoraceous root parasite of wheat, G. A. LEDINGHAM (*Canad. Jour. Res., 17 (1939), No. 2, Sect. C, pp. 38-51, pls. 5, figs. 3*).—*P. graminis* n. g. and n. sp. is described as parasitizing wheat roots in soil of three Ontario localities. Besides spore clusters of *Ligniera* type, large, septate zoosporangia with conspicuous tubes for zoospore discharge are present. Both resting spores and zoosporangia produce identical zoospores with two flagella of unequal length. The fungus and its life cycle are fully described and its relationship to the Plasmodiophorales is indicated by the form of the resting spore clusters, the method of nuclear division during growth of the myxamoebae, and the characteristic flagellation of the zoospores.

The effect of salicylic aldehyde on the infection of wheat by *Pythium arrhenomanes* Drechsler, and the destruction of the aldehyde by *Actinomyces erythropolis* and *Penicillium* sp., V. E. GRAHAM and L. GREENBERG (*Canad. Jour. Res., 17 (1939), No. 2, Sect. C, pp. 52-56, fig. 1*).—"Salicylic aldehyde, when added to soil at the rate of 50 p. p. m., seems to predispose wheat roots to attack by parasitic strains of *Pythium arrhenomanes*. *A. erythropolis* and a species of *Penicillium* have been found in soil from the healthy area of a field partially infected with Browning root rot. These organisms caused the disappearance of salicylic aldehyde in an artificial medium. It is suggested that lack of activity on the part of such organisms in certain areas of a field may lead to an accumulation of salicylic aldehyde or products acting in a similar manner, and that this may be a predisposing factor in the appearance of Browning root rot caused by *Pythium arrhenomanes*."

[Alfalfa diseases] (*Alfalfa Impr. Conf. Rpt., 6 (1938), pp. 27-31, 34, 35*).—The following brief papers are included: Pathological Problems in Growing Alfalfa, by L. E. Melchers and D. B. Creager; and Alfalfa Wilt and Breeding Nursery at Manhattan, by C. O. Grandfield.

The zinc content of weeds and volunteer grasses and planted land covers, L. H. ROGERS, O. E. GALL, and R. M. BARNETTE (Fla. Expt. Sta.). (*Soil Sci., 47 (1939), No. 3, pp. 237-243*).—Previous work by others on the beneficial effects of "land resting" and on the use of $ZnSO_4$ to prevent white bud of corn suggested a study of the zinc content of various indigenous and cover crop plants. Samples of 10 weeds and volunteer grasses and of the planted summer cover crops of three crotalarias collected in the fall from plats of a land-resting test on Norfolk and Hernando fine sands were analyzed by a spectrographic procedure for the Zn content of the ash. The dry matter of the weeds from plats rested for 2 yr. averaged 140 p. p. m. of Zn, and that of *Crotalaria spectabilis* planted annually 8 p. p. m. The dry matter of weeds and grasses collected from plats rested for 1 yr. averaged 70 p. p. m. of Zn, and that of the three crotalarias planted in plats in a 2-yr. rotation with corn and peanuts 21 p. p. m. These results appear to show that the weeds and volunteer grasses can absorb much larger proportions of Zn than can the planted land covers and thus apparently make available sufficient Zn to prevent the development of the white bud trouble in corn.

The control of cotton root rot in the Blackland region of Texas, H. E. REA (*Texas Sta. Bul.* 573 (1930), pp. 36).—General discussions of the methods of spread and perpetuation of *Phymatotrichum omnivorum*, prevention of further spread, and rotation as a method of control are followed by a presentation of the results of rotation studies at the Temple Substation and of the use of control methods other than rotation. The soil, climate, and flora of the Blackland region are said to be particularly favorable to the spread and perpetuation of the fungus. The strand growth spreads and perpetuates infection by continuous growth, chiefly along the live roots of susceptible hosts and from one plant to another where continuous cotton culture is practiced and where susceptible weeds occur. Further spread into uninfested portions of fields may be prevented by a barrier (at least 30 ft. wide) of sorghum between infested and uninfested areas. In the tests reported, marked and consistent control of cotton root rot was secured in rotations of cotton with nonsusceptible crops in which cotton was grown only one-fourth of the time, at least 2 yr. between cotton crops being required. Control of susceptible weeds was found to be a prerequisite to control by rotations. Increased acreages of nonsusceptible crops are frequently needed on the farms of the Blackland area to enable farmers to secure the maximum benefit from rotations for root rot control, and increased incomes from root rot immune crops may usually be secured where sufficient stock water is available by marketing these crops through livestock. Other methods of control are said to be less applicable to this region. Deep tillage requires expensive machinery, soil amendments are seldom effective in the field, commercial fertilizers are most valuable in conjunction with rotations, heavy applications of animal manure have failed to give satisfactory control under dry-land conditions, green manuring practices give uncertain control, and, while resistant cotton varieties may be found, the prospects are not judged as encouraging as are those for the further improvement of immune crops that may be grown in rotations with cotton.

Cottonseed treatment, S. G. LEHMAN. (N. C. Expt. Sta.). (*U. S. Dept. Agr., Ext. Path. No.* 37 (1939), pp. 32-40).—This is a review of some of the recent work, with a bibliography of 13 titles.

Diseases of potatoes in Idaho, J. M. RAEDER (*Idaho Sta. Circ.* 80 (1939), pp. 28, figs. 16).—This compendium presents and illustrates the important available information relating to potato diseases and their control, including the virus, fungus, bacterial, and nonparasitic affections. Special consideration is given to methods of seed treatment.

Scab immunity, D. REDDICK. (Cornell Univ.). (*Amer. Potato Jour.*, 16 (1939), No. 3, pp. 71-74, 76).—*Solanum commersonii*, *S. chacoense*, *S. caldasii glabrescens*, *S. jamesii*, and an unnamed variety, grown in soil heavily infested by *Actinomyces scabies*, are reported to have given an immune reaction over a 2-yr. period. All are said to have objectionable characters, including late maturity, long stolons, and those of the *S. commersonii* group a bitter flavor. Interspecific hybrids have been obtained, but the usefulness of these species in a breeding program for developing scab-resistant commercial sorts remains to be determined.

Reports and abstracts of papers to be presented at the sixth congress of the International Society of Sugar Cane Technologists, Baton Rouge, Louisiana, October 24, 1938, to November 5, 1938 (*Internatl. Soc. Sugar Cane Technol. Cong. [Baton Rouge, La.] Rpts.*, 6 (1938), pp. 23-26, 27-29, 31-52, 103, 104).—Abstracts of the following papers of interest to plant pathology are included: Recent Developments in Sugarcane Pathology, by E. C. Tims (La. State Univ.); Breeding and Testing Sugarcane Seedlings for Mosaic Disease Resistance, and for Gummy Disease Resistance, at the British West

Indies Central Sugar Cane Breeding Station, Barbadoes, both by G. C. Stevenson; Recent Progress in Sugarcane Disease Control in Florida, by B. A. Bourne; Some Recent Findings Regarding Fiji Disease of Sugarcane in the Philippines, and A Review of Sugarcane Diseases in the Philippines, both by G. O. Ocfemia; The Relation of Environmental Factors and Antagonistic Organisms to Root Rot of Sugarcane and Corn, by F. J. LeBeau, and Seed Selection and Roguing in the Practical Control of Mosaic Disease of Sugarcane in Louisiana, by M. L. Shaffer (both La. State Univ.); The Behavior of Mosaic on Certain Soils, and Mosaic in Regard to Cane Breeding, by H. Sorensen; Red Rot of Sugarcane, by E. V. Abbott, and *Pythium* Root Rot of Sugarcane, by R. D. Rands and E. Dopp (both U. S. D. A.); Diseases of the Sugarcane in Brazil, by A. A. Bitancourt; Minor Sugarcane Diseases in Egypt, by A. H. Rosenfeld; On the Red Stripe of Sugarcane in Brazil, by H. V. Silveira Grillo and N. Azevedo; Alternate Hosts of *B[acterium] vascularum*, by C. G. Hughes; Some Preliminary Trials on the Control of Sett-Rot in Natal, by A. McMartin; Sclerotic Disease of Sugarcane, by T. Kiryu and M. Okada; On the Nature of Resistance of Sugarcane to the Red Rot Disease, by R. E. Atkinson (La. State Univ.); A Study of the Common Mosaic of Sugarcane With Special Reference to Strains of the Virus, by E. M. Summers, *Cytospora* Rot of Sugarcane in Louisiana, by E. V. Abbott, Comparative Study of Sugarcane Mosaic in Different Countries, by J. Matz, and Sugarcane Diseases in the United States, by R. D. Rands and E. V. Abbott (all U. S. D. A.); Immunity Studies With Sugarcane Mosaic, by I. L. Forbes (La. State Univ.); Natural Hosts of *Bacterium vascularum* (Cobb) Gr. Smith in Mauritius, by G. Orlan; Stubble Deterioration, by C. W. Edger-ton, and The *Rhizoctonia* Disease of Bermuda Grass, Sugarcane, Rice and Other Grasses in Louisiana, by T. C. Ryker (both La. State Univ.); Stem Galls of Sugarcane Induced With an Insect Extract, by J. P. Martin; Dwarf or Multiple Bud Disease of Sugarcane in Louisiana, by E. C. Tims (La. State Univ.); and Effect on Factory Cane Juices and Sirups of *Leuconostoc mesenteroides* Isolated From Frost Damaged Louisiana Sugarcane of the 1937 Crop, by M. A. McCallip and H. H. Hall (U. S. D. A.).

Dry top rot disease, M. T. COOK. (P. R. Col. Expt. Sta.). (In *The Puerto Rico Sugar Manual*. New Orleans, La.: A. B. Gilmore, 1938, pp. 12, 13).—A note on this indigenous sugarcane disease, due to *Ligniera vascularum*, with bibliography.

Effect on factory cane juices and sirups of *Leuconostoc mesenteroides* isolated from frost damaged Louisiana sugarcane of the 1937 crop, M. A. McCallip and H. H. HALL. (U. S. D. A.). (*Jour. Bact.*, 37 (1939), No. 4, pp. 471, 472).—An abstract.

Temperature relations of tobacco-mosaic virus and its host, J. GRAINGER (*Phytopathology*, 29 (1939), No. 5, pp. 441-448, figs. 3).—The temperature of optimum activity for this virus was found to differ from that of the host. Virus activity was measured by its rate of travel within the tobacco plant, and host activity by the rate of growth of the shoot. Both rates were measured at various temperatures, first in greenhouses and later in constant-temperature chambers with humidity and light standardized. Low-temperature masking of symptoms, previously reported by the author (*El. S. R.*, 76, p. 207), was confirmed, growth of an infected tobacco plant at 48° F. resulting in the production of symptomless leaves. The results indicate that the virus has a certain independence of its host, insofar as reaction to temperature is concerned.

Disintegration of tobacco mosaic virus in urea solutions, W. M. STANLEY and M. A. LAUFFER (*Science*, 89 (1939), No. 2311, pp. 345-347, fig. 1).—From the experimental work reported it is concluded that this virus is rapidly disinte-

grated in 6 M urea and 0.1 M phosphate buffer at pH 7, with appearance of sulfhydryl groups, into low molecular weight protein components which contain no nucleic acid, exhibit no double refraction of flow, are insoluble in dilute buffers, and possess no virus activity. The rate of degradation varied widely with urea and electrolyte concentrations, type of electrolyte, pH, and temperature. It is believed that the results obtained may provide information on the nature of the forces which hold together the large virus molecule.

The disintegration of tobacco mosaic virus preparations with sodium dodecyl sulphate, M. SEENIVASAYA and N. W. PIRIE (*Biochem. Jour.*, 32 (1938), No. 10, pp. 1707-1710).—"The kinetics of the disintegration of a tobacco mosaic virus preparation by sodium dodecyl sulfate are described and also the preparation and properties of the resulting unstable protein."

Vegetable seed treatment, J. G. HORSFALL. (N. Y. State Expt. Sta.). (*U. S. Dept. Agr., Ext. Path. No. 37* (1939), pp. 26-32).—A summary of recent progress, with 10 literature references.

Bean bacterial wilt, F. HEDGES (*U. S. Dept. Agr. Leaflet 174* (1939), pp. 6, figs. 6).—This is an information leaflet (E. S. R., 58, p. 547).

Mild-mosaic virus of broad bean, T. F. YU (*Phytopathology*, 29 (1939), No. 5, pp. 448-455, fig. 1).—The author describes a new virus and the symptoms induced in several leguminous hosts. The virus was transmitted by *Aphis rumicis* and *Macrosiphum pisi*, and also by artificial juice inoculations with carborundum. It remained active for 3 hr. at 22°-24° C., but was inactivated at ±55°-60°. A dilution of 1:1,500 was tolerated. The bibliography contains 25 references.

Studies of the nature of root knot resistance, K. C. BARRONS. (Ala. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 4, pp. 263-271, pl. 1).—Microscopical study of seedling rootlets of the resistant Alabama No. 1 and of the susceptible Kentucky Wonder beans indicated that about the same numbers of larvae of *Heterodera marioni* had entered the one as the other. Further study of the rootlets of a number of resistant and susceptible varieties and species of plants confirmed these initial results. More detailed observations and experiments on Hopi 155 lima bean in the field and in inoculated soil and on roots of different ages led to the hypothesis that resistance to root knot is due to substances synthesized by the plant that counteract the giant-cell-inducing effect of the salivary secretions of the larvae. Such an explanation is said to account for the known facts concerning hereditary resistance to this parasite. Two fundamentally important questions are postulated by the results, viz, whether host specialization may not be due to genetic differences in the chemical nature of salivary secretions and the resulting ability to induce giant-cell formation rather than to differences in ability to perceive and enter the host, and whether resistant plants may not be superior as trap crops, due to the fact that as many larvae appear to enter the roots of resistant as of susceptible plants, but with failure to reproduce in the former.

Tests demonstrate commercial value of resistant cabbage, O. A. REINKING and W. O. GLOYER (*Farm Res. [New York State Sta.]*, 5 (1939), No. 2, pp. 7, 8, 9, fig. 1).—Extensive trials of both resistant and nonresistant domestic and Danish varieties on infected and healthy soils indicated that all the accepted commercial resistant varieties possess a high resistance, that in the yield tests on healthy soil in a dry year the resistant varieties yielded somewhat less than the nonresistant, and that when grown on sick soil the latter varieties produced no crop while the resistant ones gave normal yields. The investigation indicates "that there still is room for another midseason or domestic type of resistant cabbage better adapted to New York State cabbage centers. The

greatest need is for a good high-yielding, late, resistant variety. . . . In the meantime, growers will have to depend upon the resistant varieties reported upon here."

A new *Fusarium*-wilt-resistant tomato, M. C. STRONG (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 3, pp. 164-169, figs. 3).—The development of a *Fusarium*-wilt-resistant strain of John Baer, otherwise similar to the commercial variety, is reported to have been produced by a process of selection (1934-38) in soil artificially infected with 50 isolates of *F. lycopersici* obtained from 15 States and from Australia and South Africa. It is said to require 63-73 days from transplanting of medium-sized seedlings not yet in bloom to the first commercial harvest, and it is believed to be adapted to all regions where the original variety is grown, particularly where this wilt is present, and to compare favorably in resistance to such well-known varieties as Marglobe and Pritchard. On a heavily infested soil this strain yielded 20 tons of fruit per acre, as against 8 tons by the commercial variety.

Nailhead spot of tomato, caused by *Alternaria tomato* (Cke.) n. comb., G. F. WEBER (*Florida Sta. Bul.* 332 (1939), pp. 54, figs. 16).—This bulletin details the results of experimental work and presents a compendium of information on tomato nailhead spot (83 literature references). This disease has been known in Florida for 25 yr., and is said to be responsible for millions of dollars worth of damage to the crop in Cuba, West Indies, Mexico, and the United States. Tomato, potato, eggplant, and horsenettle are all susceptible, and the different phases of the disease are described. The causal fungus has been transferred from *Macrosporium tomato* to *A. tomato* n. comb., and published errors concerning the disease it causes are pointed out. Certain physiological and morphological characteristics of the fungus are discussed, as well as the seasonal development of the spontaneous and experimental disease. The pathogenicity of the parasite was proved, and the morbid anatomy of the disease is demonstrated and explained.

Crystalline preparations of tomato bushy stunt virus, F. C. BAWDEN and N. W. PIRIE (*Brit. Jour. Expt. Path.*, 19 (1938), No. 4, pp. 251-265, pl. 1, fig. 1).—The authors describe the isolation of a protein, probably identical with the virus, from infected tomato plants which not only differs from the normal plant proteins but also differs more from the other purified plant viruses than these differ among themselves. It is said to be fully crystalline, to have a higher nucleic acid content than tobacco mosaic or potato "X" viruses, and to be more stable towards pH changes but less so towards dehydrating agencies. Its particles are not elongated, and liquid and solid preparations are isotropic. When rubbed on *Nicotiana glutinosa*, 1 cc. of solution containing 10^{-7} gm. produced infections, and 1 cc. containing 10^{-8} gm. gave a specific precipitate with antiserum. Precipitates of the rod-shaped viruses with their antisera resemble those of the bacterial flagellar (H) antigens, while those of bushy stunt virus resemble those of the somatic (O) antigens. Irradiated with ultraviolet light or treated with HNO_3 , the virus loses its infectivity, but it can still be crystallized and still retains its serological activity.

The preservative effect of some reducing systems on the virus of tomato spotted wilt, R. J. BEST (*Austral. Jour. Expt. Biol. and Med. Sci.*, 17 (1939), No. 1, pp. 1-17, fig. 1).—Hydrogen in the presence of platinized platinum was found to arrest the normal aerobic inactivation of the virus, and thereafter to maintain the activity at a constant level for the duration of the test (8 hr.). Suspensions of the virus in the presence of cystein and absence of oxygen were kept in an active state for 35 days as compared to the normal in vitro "life" of a few hours. The sodium salts of glutathione, and thioglycolic and ascorbic

acids (all buffered at pH 7), preserved the virus against rapid aerobic inactivation. Adrenaline had no significant effect on the activity of suspensions exposed to air, but protected the virus against the slow inactivation occurring in the absence of oxygen. Redox potentials of the test systems are presented and discussed in relation to the relative efficiencies of the protective agents.

Several species of *Pythium* causing blossom-end rot of watermelons, C. DEBOESLER. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 5, pp. 391-422, figs. 14).—Watermelon decay due to one or another of nine known species of *Pythium* has been found widely distributed in the United States. Where the crop grows and matures under moderately dry conditions the damage is usually insignificant, but rather substantial losses result in some parts of the Middle Atlantic States where during wet seasons a late crop is exposed to more abundant infection. For control under conditions favoring decay, an application of a suitable adhesive fungicidal paste to the flower scar is suggested. Normally the causal fungi enter uninjured fruit at the flower scar, their further advance being manifested externally either in a water-soaked appearance or a dark-brown discoloration, depending largely on the parasite concerned. Illustrated descriptive accounts of three species inducing dark-brown blossom-end rot (*P. acanthicum*, *P. periplocum*, and *P. helicoides*) are given to supplement the previously published diagnoses, discussion of the morphological features of *P. helicoides* entailing comparison especially with *P. proliferum* and the application accorded the latter species by various writers. Similar discussion is devoted also to *P. anandrum*, one of many species capable of causing experimental decay but thus far not known to occur spontaneously on watermelon fruits in the field. The morphological parallelism of *P. anandrum* and *P. megalacanthum* is noted. A bibliography of 32 references is given.

Fusarium wilt resistant watermelons, H. T. COOK and T. J. NUGENT. (Va. Truck Expt. Sta.). (*Peninsula Hort. Soc. [Del.] Trans.*, 52 (1938), pp. 30-38, figs. 2).—This note discusses several resistant varieties tested or developed by the station (H. S. R., 78, p. 650). The results of the 1938 tests showed particularly the extreme resistance of the Hawkesbury variety, none of this or the Kleckly Sweet hills being killed by wilt, while 5 percent of the Leesburg and 20 percent of the Klondike hills died. The data are summarized in a table.

Fruit diseases in 1938, W. D. MILLS. (Cornell Univ.). (*N. Y. State Hort. Soc. Proc.*, 84 (1939), pp. 7-13).—A summary of the season's local disease situation for apple, stone fruits, strawberry, grape, and raspberry.

A note on the occurrence of *Marasmius pyrinus*, V. K. CHARLES. (U. S. D. A.). (*Mycologia*, 31 (1939), No. 2, pp. 228-230, fig. 1).—A note on a case of this rarely collected fungus occurring on apple fruit.

Will insoluble copper sprays control bitter rot under conditions favorable to the disease?—1938 results, K. J. KADOW, S. L. HOPPERSTEAD, and M. W. GOODWIN. (Univ. Del.). (*Peninsula Hort. Soc. [Del.] Trans.*, 52 (1938), pp. 99-102).—The results reported confirm the belief that insoluble coppers are unreliable for apple bitter rot control, but they appear to be efficient for fruit spot, sooty blotch, and fly speck. However, before they are recommended generally their influence on lead arsenate-lime sprays for codling moth should be considered. The insoluble coppers caused much less fruit injury than bordeaux mixture, but were not as effective in preventing arsenical injury to the leaves, though some were commercially satisfactory. It is believed that the reduced russetting of the fruit by insoluble coppers may be a function of their inferior sticking powers.

The use of calcium cyanamid for the destruction of apothecia of *Sclerotinia fructicola*, G. A. HUBBS and K. BAUER. (West. Wash. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 5, pp. 436-441, figs. 2).—"Commercial pulverized

and oiled calcium cyanamide, applied with a knapsack duster to the surface of the soil and vegetative cover under prune trees at the rate of 220 lb. per acre at the beginning of apothecial production, destroyed apothecia of *S. fructicola* and prevented the development of others. Similar results were obtained when soil in wooden boxes, in which apothecia were developing, was treated with a surface application of calcium cyanamide at the rate of 32½ lb. per acre."

Red stele—a new disease of the strawberry, J. H. CLARK (*N. J. State Hort. Soc. News*, 19 (1938), No. 6, p. 1050).—This is a brief summary of data concerning a disease first reported in the United States in 1935, with special reference to New Jersey where it was found in 1938 on 4 of 40 farms inspected. The Pathfinder variety is said to be markedly resistant, and other varieties have shown some promise. The building up of a healthy stock of plants is strongly recommended.

A note on currant anthracnose, C. W. ROBERTSON. (Mich. State Col.). (*Phytopathology*, 29 (1939), No. 5, p. 459).—In western Michigan, *Pseudopeziza ribis* was observed (1938) to have caused a severe yellowing and defoliation on Pres. Wilder currants, whereas no appreciable injury was seen on Prince Albert bushes in a nearby planting. *Mycosphaerella grossulariae* leaf spot was found on both varieties, but significant differences in resistance were not observable.

Disease attacks the persimmon, R. K. BEATTIE and B. S. CRANDALL (*Amer. Forests*, 45 (1939), No. 3, pp. 120, 121, 124, figs. 5).—This is a description and discussion of the hosts and distribution of the *Cephalosporium* disease previously noted as affecting *Diospyros virginiana* (E. S. R., 79, p. 645). Its spread over a large southern area is deemed particularly regrettable because of the value of this tree for soil conservation and erosion control.

Synergism in fruit-rotting fungi, A. R. GEMMELL (*Chron. Bot.*, 5 (1939), No. 1, pp. 41, 42).—The author presents an explanation based on his own experiments of the mutually advantageous relationship of *Penicillium digitatum* and *Oospora citriaurantii* causing a rot of citrus noted by Savastano and Fawcett (E. S. R., 61, p. 747).

Observations on so-called decline disease, R. H. POSTLETHWAITE (*Date Growers' Inst. Rpt.*, 15 (1938), pp. 5-7).—This is a brief review of published work by others and observations by the author on this disease of date palms, with discussion by K. Peck, [D. E.] Bliss, and [H. S.] Fawcett.

Disease-free parents for psorosis prevention, H. S. FAWCETT. (Calif. Citrus Expt. Sta.). (*Pacific Rural Press*, 137 (1939), No. 12, p. 280, figs. 2).—See also a previous note (E. S. R., 80, p. 505).

Spoilage of dates as related to management of the fruit bunch, D. E. BLISS. (Calif. Citrus Expt. Sta.). (*Date Growers' Inst. Rpt.*, 15 (1938), pp. 7-12, fig. 1).—The most important indication believed to have been obtained by these studies refers to the effects on fruit rot of aeration by fruit strand separation, by bags allowing increased ventilation of the fruit, and by removal of fruit strands from the center of the bunch. During two moderately wet years all three methods proved effective, but more so in combination than singly, while in the one dry year there was no decrease in rot with aeration. The principles involved in producing the best fruit are good nutrition and ripening in a relatively dry atmosphere. The types of bunch management satisfying these conditions must be varied to suit local seasonal and other conditions.

Flower-spot of azaleas: Directions given for identification and control, F. WEISS. (U. S. D. A.). (*South. Florist and Nurseryman*, 46 (1939), No. 22, pp. 5, 12, 13, 16, 17).—This is in the nature of a preliminary report on this recently recognized disease (*Opuntia azaleae*) of cultivated azaleas, observed in all the Southeastern and Gulf Coast States from North Carolina to Louisiana.

The fungus is known also to infect flowers of rhododendron, mountain laurel, and some species of *Vaccinium*. The sclerotium is said to be the most vulnerable stage of the parasite, and sanitary control measures are directed there. Copper sprays or dusts may have some control value if applications are made prior to or coincident with the period of ascospore discharge, and acetic acid is said to have shown fungicidal possibilities with no apparent toxic effect on azaleas when properly diluted. In any trials these materials should be applied to the ground surface beneath the bushes, as well as lightly but thoroughly over the foliage, starting as soon as any buds show color and repeating at 3-day intervals until the blooms are fully open.

The *Verticillium* disease of chrysanthemums and its control, P. E. TILFORD, H. A. RUNNELS, and C. MILLER. (Ohio Expt. Sta. et al.). (*Chrysanthemum Soc. Amer. Bul.*, 7 (1939), No. 1, pp. 9-16).—The symptoms of the *V. dahliae* disease are described, and tests are reported as showing that roguing the diseased plants from the stock and selecting the more vigorous individuals for propagation greatly reduces the incidence. According to the results of variety tests the large flowering, exhibition, pompon, anemone-flowered, daisy-type, pot-plant, hardy, and Korean varieties included are each grouped according to susceptibility and resistance.

Two new diseases of gladioli, R. NELSON. (Mich. State Col.). (*Gladiolus Ann.*, 1939, pp. 32-37).—A summary is given of present information on *Fusarium* yellows (E. S. R., 79, p. 499), the history of which appears to be comparatively recent, and of progress in tests to segregate the resistant and susceptible varieties (with lists). Another disease said to be increasing in commercial stocks but to be much less serious is the basal dry rot (*Fusarium* sp.), which is described with suggested control measures.

Fungicides for roses, L. M. MASSEY. (Cornell Univ.). (*Amer. Rose Ann.*, 1939, pp. 103-111).—The author summarizes present recommendations for rose disease control by the various sulfur and copper fungicides, with special reference to the experimental results at Ithaca.

Roguing of dark red tulips for mosaic disease, F. P. McWHORTER. (Oreg. Expt. Sta.). (*Florists Each. and Hort. Trade World*, 92 (1939), No. 3, p. 17).—By means of inoculation studies the type of "break" which may be expected in 49 varieties of red Mendel tulips was determined. The results are tabulated and discussed, with the base color of the plant indicated in each case. The generalization that all blue-base pigments accompany self-break is not applicable to all other kinds of red tulips, but the probability that all blue-based varieties will "self" should, it is believed, be of real value in roguing tulips when complete elimination of virus-infected bulbs is desired.

Some important shade tree diseases of the Mid-West, F. C. STRONG. (Mich. State Col.). (*Natl. Shade Tree Conf. Proc.*, 14 (1938), pp. 106-118, figs. 7).—This is a general discussion of the more important parasitic and non-parasitic diseases, including drought and winter injuries, chlorosis (parasitic and nutritional forms), cedar rust, leaf diseases, wilts (particularly of elm and maple), cankers, and chestnut blight.

Eradication of the cultivated black currant in white pine regions, J. F. MARTIN (U. S. Dept. Agr. Leaflet 175 (1939), pp. 8, figs. 5).—This is an information leaflet relating to white pine blister rust control by black currant eradication.

A study of *Botryosphaeria ribis* on willow, F. T. and F. A. WOLF (*Mycologia*, 31 (1939), No. 2, pp. 217-227, figs. 4).—A disease of willows due to *B. ribis* is characterized by cankers on the twigs, larger branches, and trunk, successive blighting of the branches finally resulting in the death of the tree.

A single stroma on willow may at one time bear conidia, microconidia, and ascospores. Cultures from conidia or from ascospores were similar, and the *Dothiorella* stage was produced from both. The conidia were found to be multinucleate but borne on uninucleate conidiophoral cells. The development of nuclei in the ascus is like that of other Ascomycetes. The ascospores are uninucleate when delimited but become multinucleate as they mature. For a time after germination the hyphal cells are also multinucleate. There are 11 literature references.

Poria andersonii and *Polyporus glomeratus*, two distinct heart-rotting fungi, W. A. CAMPBELL and R. W. DAVIDSON. (U. S. D. A.). (*Mycologia*, 31 (1939), No. 2, pp. 161-168, figs. 2).—Characters in nature and in culture and the distribution were studied for these two species. *Poria andersonii* is one of the fungi commonly isolated from trunk decay in living oaks throughout the Middle West, causing a white decay resembling that due to *Fomes everhartii* and entering usually through branch stubs but also through fire scars or other injuries. *Polyporus glomeratus* induces a white to light brown spongy heart rot of maples and is common (especially on sugar maples) in some parts of the Lake States. There are 11 literature references.

The biology of the meadow nematode *Pratylenchus pratensis* (De Man) Filipjev 1936, R. J. HASTINGS (*Canad. Jour. Res.*, 17 (1939), No. 2, Sect. D, pp. 39-44).—"The meadow nematode completes its life cycle in 54 to 65 days—25 to 31 days from the larval stage to the adult, and 29 to 34 days from maturation to the second generation. Eggs are deposited by a single female at the rate of not more than one a day. The largest number of eggs laid by a single female in one place was 16, owing apparently to migratory habits. The total number of eggs from a single female could not be determined. The adult male and female and all larval stages of this species are capable of entering the roots of oats. They are very susceptible to desiccation. No living nematodes were recovered from invaded root tissue that was allowed to dry. In moist excised oat roots the nematodes remained viable for more than 30 days, but in water the majority died within the same period. A 10-min. immersion of infested oat roots in hot water will destroy the meadow nematode only when the temperature is 120° F., or higher."

Predaceous nematodes of the genus *Aphelenchoides* from Hawaii, J. R. CHRISTIE (U. S. D. A.). (*Jour. Wash. Acad. Sci.*, 29 (1939), No. 4, pp. 161-170, figs. 3).—The author refers to the work of Linford and Oliveira (E. S. R., 77, p. 65) on nemas preying on other nemas, including *Heterodera marioni*, and presents drawings and descriptions of five cultures of the "long tailed" group of *Aphelenchoides* received from these authors—one a new variety and three of them new species. A key to the five species studied is provided.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Animal ecology, A. S. PEARSE (*New York and London: McGraw-Hill Book Co.*, 1939, 2. ed., pp. XII+642, figs. 133).—A complete revision of the work noted (E. S. R., 55, p. 657), to which seven chapters have been added.

Animal communities in temperate America, as illustrated in the Chicago region: A study in animal ecology, V. E. SHELFORD (*Geog. Soc. Chicago Bul.* 5, 2. ed., [1937], pp. XIII+368, [pls. 2], figs. [315]).—In this second edition (E. S. R., 32, p. 549) the subject is dealt with in 15 chapters, followed by an appendix on methods of study and a bibliography of 214 titles.

Simple methods by which farmers and sportsmen can improve wildlife habitats on agricultural lands, J. N. MORTON (*Pa. Game Comm. Bul.* 16 (1938), pp. 40, figs. 46).

[Contributions in economic zoology] (*Kans. Acad. Sci. Trans.*, 41 (1938), pp. 299-302, 317-329, 331-367, 379-384, 387-394, figs. 16).—Contributions presented in March and April 1938 are: Susceptibility of Mature Chickens to Tapeworm Infections, by J. E. Ackert and A. A. Case (pp. 299-302) (*Kans. Expt. Sta.*); Effects of Nicotine on Rats (Albino), by H. E. Branch and W. G. Moss (pp. 317-329); The Frogs and Toads of the Southeastern United States, by C. E. Burt (pp. 331-367); Transmission of Poultry Parasites by Birds With Special Reference to the "English" or House Sparrow and Chickens, by W. L. Hoyle (pp. 379-384); and An Attempt at an Ecological Evaluation of Predators on a Mixed Prairie Area in Western Kansas, by L. D. Wooster (pp. 387-394).

[Contributions on entomology and ornithology] (*Jour. Agr. Univ. Puerto Rico [Col. Sta.]*, 22 (1939), No. 4, pp. 483-512, fig. 1).—Contributions presented are: Alternate Host Plants of the Pink Bollworm (*Pectinophora gossypiella* (Saund.)) in Puerto Rico, by L. C. Fife (pp. 483-492), A Search in the Guianas and Trinidad for Predatory Beetles of the Bamboo Scales (pp. 493-495) and A Dryinid Parasite [*Gonatopus* n. sp.] Attacking *Baldulus maidis* in Puerto Rico (pp. 497, 498), both by K. A. Bartlett, and Ecological Notes on Mosquitoes Associated With Bromeliads, by G. S. Tulloch (pp. 499-501) (all U. S. D. A.); and The Birds of Saba, by S. T. Danforth (pp. 503-512) (Univ. P. R.).

Standardization of the precipitin technique and its application to studies of relationships in mammals, birds, and reptiles, H. R. WOLFE. (Univ. Wis.). (*Biol. Bul.*, 76 (1939), No. 1, pp. 103-120).—In the work reported antibodies were produced in rabbits by injecting very small quantities of serum proteins of mammals, birds, and reptiles. Antisera produced by injection of a minimum quantity of antigen were the most specific as determined by the "ring" method. Occasionally the serum proteins of such closely related animals as ox and sheep or gray squirrel and red squirrel could be distinguished. Antiserum dilutions as low as 1:3 at times eliminated the heterologous reaction. The ring appeared in the homologous and very closely related protein solutions earlier than in the more distantly related ones when incubated at temperatures of $37^{\circ}\pm 1^{\circ}$ C. It was not possible to distinguish between the buffalo and ox serum proteins or between the goat and sheep serum proteins. Serological relationship studies of birds and reptiles seem feasible. The procedures have not been entirely new, but the necessity for uniformity and standardization of methods has been emphasized.

A list of 17 references to the literature cited is included.

Protection of mountain apiaries from bears by use of electric fence, T. I. STOREY, G. H. VANSSELL, and B. D. MOSES. (Univ. Calif. and U. S. D. A.). (*Jour. Wildlife Mangt.*, 2 (1938), No. 4, pp. 172-178, fig. 1).

Beaver food utilization studies, S. E. ALDOUS (*Jour. Wildlife Mangt.*, 2 (1938), No. 4, pp. 215-222, pl. 1, figs. 4).—Aspen is shown to be the most important food species of beavers in the Superior National Forest, Minn., with birch, alder, and willow next in rank. "The degree of utilization of aspen based on measurements of 456 trees was 36 percent and of waste 64 percent. The greatest complete wastage occurs in trees between 4 and 6 in. in diameter because there is usually a heavier stand of these sizes and more of the cut trees lodge, thus preventing utilization. Feeding experiences show that beavers consume between 22 and 33 oz. of aspen bark and twigs daily."

The jack rabbit brings money to North Dakota, S. SAUGSTAD (*North Dakota Sta. Bmo. Bul.*, 1 (1939), No. 4, pp. 8-10).—Attention is called to the economic value of jack rabbit skins and carcasses, the sales of which in the State have reached as high as \$100,000 annually. It is pointed out that the

potential income from this source in the State should not be overlooked whenever a proposed program of extermination is considered.

A water rat (*Hoplochilus sciureus berbicensis* Morrison-Scott) damaging sugar-cane in British Guiana, L. D. OLEARE (*Agr. Jour. Brit. Guiana*, 9 (1938), No. 4, pp. 217-229, pls. 3).—An account is given of an outbreak of rats which occurred at Blairmont Estate, Berbice, British Guiana. The rat concerned represents a new subspecies known as *H. sciureus berbicensis*.

Notes on the den ecology of the striped skunk in Iowa, L. F. SELKO. (Iowa Expt. Sta., U. S. D. A., et al.). (*Amer. Midland Nat.*, 20 (1938), No. 2, pp. 455-463, figs. 5).—The results of observations of the prehibernation den environment of striped skunks in the autumn, the den environment of individual skunks in the spring and summer, and the den environment of skunk families in the spring and summer are reported, the details being given in tables.

Notes on the southern woodchuck in Missouri, A. R. TWICHELL. (Univ. Mo.). (*Jour. Mammal.*, 20 (1939), No. 1, pp. 71-74).—In reporting on the biology of the southern woodchuck (*Marmota monax monax*), observed in central Missouri, the author records *Ixodes texanus* as the only external parasite detected. The largest number found on a single animal has been 6. *Oboliscoides cuniculi* was the only endoparasite found in 19 animals examined, 6 having been attached to the mucosa of one stomach and 2 to another.

Catalogue of birds of the Americas, XI, C. E. HELLMAYR (*Field Mus. Nat. Hist. [Chicago] Pub., Zool. Ser.*, 13 (1938), pt. 11, pp. VI+662).—A continuation of this work (E. S. R., 79, p. 215) in which the families Ploceidae, Catamblyrhynchidae, and Fringillidae are cataloged.

A synopsis of North American birds of prey and their related forms in other countries, L. R. WOLFE (*Bul. Chicago Acad. Sci.*, 5 (1938), No. 8, pp. 167-208, figs. 10).—The distribution of the species and subspecies of birds of prey which occur in North America and their geographical races in other parts of the world are briefly outlined. Major characters which separate the forms are indicated, but no attempt is made at complete descriptions.

The birds of tropical west Africa, with special reference to those of the Gambia, Sierra Leone, the Gold Coast, and Nigeria, V. D. A. BANNEEMAN (*London: Crown Agents for Colonies*, 1939, vol. 5, pp. XLIII+485, pls. [11], figs. [138]).—This further volume (E. S. R., 79, p. 71) is devoted to seven families of the large order of Passeriformes, or perching birds, in addition to the eight dealt with in volume 4.

Sparrows, towhees, and longspurs, T. G. PEARSON (*Natl. Geog. Mag.*, 75 (1939), No. 3, pp. 353-376, pls. 8, figs. 5).—This descriptive account includes eight colored plates which illustrate the forms considered.

Recent disastrous effects of oil pollution on birds in the San Francisco Bay region, J. MOFFITT and R. T. ORR (*Calif. Fish and Game*, 24 (1938), No. 3, pp. 239-244, figs. 2).—A report of observations of water fowl following oil pollution of coastal waters contiguous to San Francisco Bay as the result of an oil tanker shipwreck. Of the offshore species of birds, California murrelets suffered most, followed by scoters and western grebes. "Offshore ranging forms such as murrelets, auklets, shearwaters, and petrels were apparently spared because the oil did not extend sufficiently far from shore to embrace their habitats. In the quiet bays, western grebes, white-winged scoters, ruddy ducks, eared grebes, and red-throated loons suffered most in the order named."

Seasonal abundance of some parasites of wild ducks, W. C. GOWER (*Jour. Wildlife Mgmt.*, 2 (1938), No. 4, pp. 223-232, figs. 5).—In this report the prevalence, both total and seasonal, and something of the host-parasite relation-

ships are discussed for 11 genera of wild duck parasites. A list of 15 references to the literature cited is included.

The great horned owl as an indicator of vulnerability in prey populations, P. L. ERRINGTON. (Iowa Expt. Sta.) (*Jour. Wildlife Mgmt.*, 2 (1938), No. 4, pp. 190-205, pls. 4).—This contribution is presented with a list of 23 references to the literature cited.

Some saw-whet owls in central Iowa, T. G. SCOTT. (Iowa Expt. Sta.). (*Wilson Bul.*, 50 (1938), No. 4, pp. 239-242, fig. 1).—Data on the habits of a saw-whet owl *Cryptoglaux acadica acadica* in central Iowa, where it is an uncommon and irregular visitor, obtained during the winter of 1936-37, have shown about 97 percent of the food to have consisted of mice and shrews. White-footed and meadow mice formed the greater part of the food, 60 percent of the total prey having been white-footed mice. The remaining 3 percent of the food was birds, thought to be slate-colored juncos.

The food and cover relationship in the winter survival of the ring-necked pheasant (*Phasianus colchicus torquatus* Gmelin) in northern Iowa, W. E. GREEN. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 12 (1938), No. 3, pp. 285-314, figs. 30).—Studies conducted on a tract of 4,900 acres in Winnebago County, Iowa, from November 11, 1935, to March 5, 1936, are reported.

Greater prairie chicken breeding in Davis County, Iowa, 1938, M. F. BAKER and G. O. HENDRICKSON. (Iowa Expt. Sta., U. S. D. A., et al.). (*Iowa Bird Life*, 8 (1938), No. 4, pp. 46-49, fig. 1).—A report based upon observations of *Tympanuchus cupido americanus* Reich. through five summers.

Studies of the nesting cycle of the California valley quail in 1937, B. GLADING. (U. S. D. A.) (*Calif. Fish and Game*, 24 (1938), No. 4, pp. 318-340, figs. 11; also in *Calif. Conserv.*, 4 (1939), No. 1, pp. 3-6, figs. 3).—In the studies reported, based upon observations of the California valley quail (*Lophortyx californica vallicola*) found on the San Joaquin Experimental Range in Madera County, Calif., the average clutch size in 40 incubated nests was found to be 10.97 eggs. The average brood size in 16 hatched nests was 10.18 young.

Censusing quail in early fall, L. J. BENNETT and G. O. HENDRICKSON. (Iowa Expt. Sta., U. S. D. A., et al.). (*Jour. Wildlife Mgmt.*, 2 (1938), No. 4, pp. 169-171).

The crawfishes of Mississippi, with special reference to the biology and control of destructive species, C. LYLE (*Iowa State Col. Jour. Sci.*, 13 (1938), No. 1, pp. 75-77).—Notes on the biology and control of the crawfish (*Cambarus hagenianus*), which inhabits the lime soils of Mississippi and Alabama and on rainy spring nights often destroys entire fields of young corn and cotton, are presented.

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 150-156).—The contributions presented (E. S. R., 80, p. 651) are: The Dung Rolling Beetle [*Canthon pilularius* (L.)] as a Host of a Sarcophagid Parasite [*Sarcophaga alcedo* Ald.], by K. A. Bartlett (p. 150), Breeding Areas of the Tomato Psyllid *Paratrioza cockerelli* (Sulc.), by V. E. Romney (p. 150), and *Peregrinator biannulipes* Montr., a Predator of the Bamboo Powder-Post Beetle in Porto Rico, by H. K. Plank (p. 151) (all U. S. D. A.); A Disease of the Corn Ear Worm (*Heliothis obsoleta* (F.)), by N. Stahler (Univ. Calif.); A Feed Record of *Pterostichus* (*Pocillus*) *chalcites* (Say) Upon June Beetle Eggs and Grubs, by L. Seaton (pp. 151, 152) (U. S. D. A.); A Black Scale Parasite [*Diversinervus* sp.] With Promising Qualities, by S. E. Flanders (p. 152) (Calif.

Citrus Expt. Sta.) ; *Prophanurus alecto* Crawford in Porto Rico, by G. N. Wolcott (pp. 152, 153) (P. R.) ; Tartar Emetic in the Control of Citrus Thrips on Lemons, by A. M. Boyce and C. O. Persing (p. 153) (Calif. Citrus) ; Lead Arsenate as a Possible Control for the White Grub [*Phyllophaga* sp.] in Strawberries, by T. W. Kerr, Jr., (p. 153) (Cornell Univ.) ; Magnesium Oxide as a "Corrective" for Cryolite Sprays, by S. Marcovitch (pp. 153, 154), and Wool Grease or Degras as a Substitute for Mineral Oil in Sprays, by S. Marcovitch and W. W. Stanley (p. 154) (both Tenn.) ; An Agar Preparation for Feeding Adult Parasite Insects, by J. K. Holloway (p. 154) (U. S. D. A.) ; The Asparagus Beetle in Utah, by G. F. Knowlton (pp. 154, 155) (Utah) ; Notes on *Empusa grylli* in Oklahoma, by R. R. Walton and F. A. Fenton (pp. 155, 156) (Okla.) ; Notes on Food for Corn Ear Worm Adults, by E. V. Walter and D. W. LaHue (p. 156) (U. S. D. A.) ; and Elm Leaf Beetle in Utah, by G. F. Knowlton and F. C. Harmston (p. 156) (Utah).

[Report of work in entomology] (*California Sta. [Bien.] Rpt. 1937-38, pp. 47-54, 95*).—The work of the biennium 1937-38 referred to (E. S. R., 76, p. 824) includes new parasites for red and black scale, control of scales on citrus by chemicals, dusts for the orange tortrix, second-brood codling moth on walnuts, walnut husk fly, sprays for red spiders and for the mealy plum aphid, control of thrips on various crops, pear leaf blister mite, cyclamen mite, control of globe-artichoke insects, cotton pests in the San Joaquin Valley, importance of bee culture in California, bee losses from poisonous dusts, improved methods of bee shipping, and electric protection for mountain apiaries from bears.

[Work in entomology by the Delaware Station] (*Delaware Sta. Bul. 214 (1938), pp. 22-26*).—The work of the year (E. S. R., 78, p. 510) briefly reported relates to the occurrence of several important insects and factors responsible for the development of one and two annual broods of the plum curculio, both by L. A. Stearns ; bionomics and control of the codling moth, by Stearns, R. L. Pierpont, W. W. Fassig, and P. L. Rice, of the oriental fruit moth, by Stearns and Rice, and of the Tabanidae of Delaware, by D. McCreary ; and mosquito investigations, including the effect of ditching on muskrat production, by Stearns, MacCreary, and F. C. Daigh.

[Work with economic insects by the Florida Station]. (Partly coop. U. S. D. A.). (*Florida Sta. Rpt. 1938, pp. 82, 83, 84-86, 106, 107, 146, 147, 153, fig. 1*).—The work of the year referred to (E. S. R., 79, p. 502) includes miscellaneous observations ; the Florida flower thrips *Frankliniella cephalica bispinosa* Morg. and the onion thrips, both by J. R. Watson ; the introduction and propagation of beneficial insects, particularly the Chinese ladybeetle *Leis dimidiata 15-spilota* Hope, by Watson and W. L. Thompson ; control of the leaf-footed bug on Satsuma oranges, by H. E. Bratley ; control of fruit and nut crop insects, particularly the nut case-bearer, by S. O. Hill, Watson, and Bratley ; the gladiolus thrips and the pepper weevil, both by Watson and J. W. Wilson ; the biology and control of Florida aphids, including the corn leaf aphid and the grapevine aphid, and the discovery of three species of gall-forming aphids (the woolly elm aphid, *Georgiaphis ulmi* (Wilson), and *Colopha graminis* (Monell)) on elms at Gainesville, by A. N. Tissot ; fumigation of green cowpea pods, tomato plants, and seeds, by R. J. Wilmot ; the orange tortrix and the coccid moth *Latilia coccidivora* Comst. and control of purple scale and white flies with lime-sulfur, both by Thompson at the Citrus Substation ; and control of the bean jassid and the pea aphid by R. N. Lobdell at the Everglades Substation.

Pest eradication work in Florida, J. F. COOPER. (Fla. Expt. Sta.). (*Citrus Indus., 19 (1938), No. 9, pp. 5, 9, 16, 17, 20, figs. 2*).—A summary is given of

work directed by the State Plant Board in eradicating many of the insect pests and other serious enemies of agriculture in Florida.

[Contributions on economic insects] (*Kans. Acad. Sci. Trans.*, 41 (1938), pp. 181-191, figs. 11).—Contributions presented in March and April 1938 are: Parasite Emergence Holes as an Aid in Determining Hessian Fly Infestation in Mature Wheat Plants, by E. T. Jones (pp. 181, 182) (U. S. D. A.); and A Preliminary Report on the Insects Attacking Bindweed, With Special Reference to Kansas, by R. C. Smith (pp. 183-191) (Kans. Expt. Sta.).

[Work in entomology by the New York State Station] (*New York State Sta. Rpt. 1938*, pp. 19-21).—Brief report is made of work with economic insects and their control, including especially forms attacking the apple, peach, and cherry, vegetables (the European corn borer, corn earworm, pea aphid, pea weevil, Mexican bean beetle, cabbage aphid, cabbageworms, etc.), and several injuring ornamental and nursery plants.

[Contributions on fruit and nut insects and their control] (*Oreg. State Hort. Soc. Ann. Rpt.*, 30 (1938), pp. 65-68, 72-84, 141-147).—Among the contributions presented at the annual meeting in December 1938 are the following: Insect Pests of Small Fruits, by W. D. Edwards (pp. 65-68) (Oreg. State Col.); Report of the Cherry-Fruit Fly Committee, by A. C. Berntzen (pp. 72-74); Biology and Control of the Cherry Fruit-Fly in the Willamette Valley, 1938, by S. C. Jones (pp. 75-78) (Oreg. State Col.); Cherry Fruit-Fly, by A. L. Marble (pp. 79, 80); Discussion on Pear Thrips on Prunes, by R. E. Rieder (pp. 81-84); Progress Report on the Control of Filbert Insects, by B. G. Thompson (pp. 141-144) (Oreg. Expt. Sta.); and Studies of Filbert Insects, by S. M. Dohanian (pp. 145-147) (U. S. D. A.).

[Work in entomology by the South Dakota Station], H. C. SEVERIN (*South Dakota Sta. Rpt. 1938*, pp. 30-32).—The work of the year (E. S. R., 79, p. 504) reported upon relates to the grasshoppers (Acrididae) of South Dakota—their economic importance, distribution, life histories, and control, and a study of the blister beetles (Meloidae) of economic importance in the State.

[Contributions on economic insects] (*Va. State Hort. Soc. Rpt.*, 43 (1938), pp. 38-46, 131-136, 162-165).—Among the contributions presented are: The Japanese Beetle Situation, by G. T. French (pp. 38-46); and A Progress Report on Ethylene Dichloride for Peach Tree Borer Control, by M. L. Bobb (pp. 131-136), and The Present Status of Scale and Aphids and Their Control, by W. S. Hough (pp. 162-165) (both Va. Expt. Sta.).

[Work in economic entomology by the Washington Station] (*Washington Sta. Bul. 368* (1938), pp. 25, 26, 27, 36-40, 84, 85, 87, 88).—The work of the year briefly reported (E. S. R., 79, p. 360) includes the chemistry of insecticides, by K. Groves and J. L. St. John; sprays for codling moth control, by Groves and H. Fallscheer; spray residue removal, by Groves, St. John, and Fallscheer; mineral oil sprays for insecticides and the possibilities of replacing lead arsenate in the control of codling moth and other injurious apple pests by insecticides nonpoisonous to man, both by R. L. Webster and J. Marshall; the control of five species of orchard spider mites, by Marshall; the influence of alfalfa on pea aphids in eastern Washington, the tomato fruitworm, and insecticidal values of dry and liquid lime-sulfur, all by Webster and R. D. Eichmann; reducing onion thrips damage to greenhouse carnation blossoms, by Eichmann; and the cherry fruitworm in western Washington, by E. P. Breakey and Webster. Work at the Irrigation Substation consisted of wireworm investigations, by K. E. Gibson (coop. U. S. D. A.). Work at the Cranberry-Blueberry Substation, by D. J. Crowley, included scale control with dormant sprays, sprays for fireworm control, and fruitworm observations.

[Reports of the entomologist for the years 1936 and 1937], A. PICKLES (*Trinidad and Tobago Dept. Agr. Rpts.*, 1936, pp. 57, 58; 1937, pp. 71, 72).—A brief report is given of the work for 1936 (E. S. R., 76, p. 502) with insects affecting sugarcane, cacao, bananas and plantains, citrus, and stored products, and for 1937, particularly on the occurrence of and control work with insects attacking sugarcane and cocoa and citrus investigations in Grenada and Carriacou.

The problems of applied entomology in Pernambuco, Brazil, [I], II, L. PYENSON (*Rev. Ent.*, 8 (1938), No. 3-4, pp. 237-254, figs. 3; 9 (1938), No. 1-2, pp. 16-31).—Part 1 of this contribution considers the conditions in Pernambuco influencing insect activities and abundance, and part 2 is a preliminary account of some of the pests of the various crops of the state that have been observed and identified.

Insects and other pests injurious to the production of seed in herbage and forage crops, H. F. BARNES (*Imp. Bur. Plant Genet., Herb. Plants [Aberystwyth]*, *Herb. Pub. Ser. Bul.* 20 (1937), pp. 31+III).—A practical summary of information contributed from the Rothamsted Experimental Station.

Insects and a mite found on cotton in Puerto Rico, with notes on their economic importance and natural enemies, L. C. FIFE (*Puerto Rico Sta. Bul.* 39 (1939), pp. 14).—A systematically arranged list of the insects and acarids found on cotton in Puerto Rico, with the natural enemies of some, is followed by brief discussions of their importance and a list of 45 references to the literature cited.

Controlling insects on raspberries, R. HUTSON (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 3, pp. 230-235, figs. 4).—A brief practical account of control measures for insects attacking the canes and foliage of the raspberry.

Citrus-cultivation and citrus-entomology in Malta, F. S. BODENHEIMER (*Hadar*, 11 (1938), No. 10, pp. 290-294).—Observations made of citrus insects of economic importance in Malta in January 1938 are reported (pp. 292-294).

Fall clean-up measures against [cloudy-winged] whitefly and scale in citrus groves, J. R. WATSON. (Fla. Expt. Sta.). (*Citrus Indus.*, 19 (1938), No. 10, p. 14).

Pests of the mango tree in the Dutch East Indies [trans. title], C. J. H. FRANSEN (*Landbouw [Buitenzorg]*, 14 (1938), No. 10, pp. 620-637; *Eng. abs.*, pp. 636, 637).—A concise account of the more important insect enemies of mango in the Dutch East Indies, presented with a list of 16 references.

[Contributions on entomological technic] (*U. S. Dept. Agr., Bur. Ent. and Plant Quar.*, 1938, ET-121, pp. 2, pl. 1; ET-122, pp. 2, pl. 1; ET-123, pp. 2, pls. 3; ET-124, pp. 2, pls. 2; ET-125, pp. 3, pls. 2; ET-126, pp. 2, pl. 1; ET-127, pp. 2, pls. 2; ET-128, pp. 2, pl. 1; ET-129, pp. 2, pls. 3; ET-130, pp. 2, pl. 1; ET-131, pp. 2, pl. 1; ET-132, pp. 2, pls. 3; ET-133, p. 1, pls. 2; ET-134, pp. 2, pl. 1; ET-135, pp. 4, pls. 2; ET-136, pp. 3, pl. 1; 1939, ET-137, pp. 2, pls. 2; ET-138, pp. 2, pls. 2; ET-139, pp. 3, pls. 4; ET-140, p. 1, pl. 1; ET-141, p. 1, pls. 2; ET-142, pp. 3, pls. 2).—Further contributions (E. S. R., 79, p. 504) are A Convenient Cage for Determining Field Populations of the Potato Leafhopper, by F. W. Poos and J. W. Scrivener (ET-121); Apparatus and Method for Filling Lepidopterous Larvae With Wax, by J. C. Silver (ET-122); A Method of Keeping Records on Replicated Plots, by J. Wilcox (ET-123); A Simple and Effective Larval Trap for Hornworms, by A. H. Madden and F. S. Chamberlin (ET-124); A Counting-Cage Heater for Winter Studies of Insect Populations in the Field, by O. A. Hills (ET-125); Modifications of Square-Foot Sampler, by H. E. Dorst (ET-126) (E. S. R., 69, p. 825); An Injector for Forcing Liquids Into the Soil, by C. B. Eaton (ET-127); Specimen Supports for Objects Photographed

From Above, by C. B. Nickels (ET-128); A Simple Method of Testing Camera Shutter Speeds for Between-the-Lens Shutters, by G. W. Still (ET-129); Emergence Cages for Light-Attracted Insects, by H. C. Donohoe (ET-130); An Improved and Inexpensive Oviposition Cage for Insectary Use, by O. I. Snapp and J. R. Thomson, Jr. (ET-131); Equipment and Methods for Estimating Dried Fruit Beetle Populations in Soil, by C. K. Fisher, and D. F. Barnes (ET-132); A Reel for Carrying Rolls of Tree-Banding Material, by M. A. Yothers and F. W. Carlson (ET-133); A Simple Hand-Operated Soil-Sifting Device, by M. A. Yothers (ET-134); A Machine for Separating Mosquito Eggs From Soil, by C. M. Gjullin (ET-135); A Suggested Method for the Determination of the Ether-Extractives Content of Small Insects, by W. C. Cook (ET-136); An Automatic Wind-Direction Recorder Adapted to an Electrical Recording Thermometer, by R. A. Fulton (ET-137); A Special Cage for Confining Insects on Tall Plants or Portions of a Plant, by O. A. Hills (ET-138); A Revolving Plant Cage for Use in Insect Selectivity Studies, by J. A. Gillett and J. R. Douglass (ET-139) (Idaho Expt. Sta.); An Improved Method of Labeling Jelly-Glass Rearing Containers (ET-140) and A Portable Stand for Outdoor Photography (ET-141), both by A. H. Madden; and A Telescopic Spray Extension Rod for Use in Bark Beetle Control Work, by J. C. Evenden (ET-142).

Plant breeding and selecting for insect resistance, R. G. DAHMS and F. A. FENTON. (U. S. D. A. and Okla. A. and M. Col.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 131-134).—A discussion of this subject in which the discovery of resistant varieties, the breeding program, and the cause of insect resistance are considered.

Host-finding by insect parasites.—I, Observations on the finding of hosts by *Alysia manducator*, *Mormoniella vitripennis*, and *Trichogramma evanescens*, J. LAING (*Jour. Anim. Ecol.*, 6 (1937), No. 2, pp. 298-317, figs. 5).—With a view to determining the manner in which certain insect parasites find their hosts, *T. evanescens* Westw. was investigated and a brief study made of certain aspects of the behavior of the braconid *A. manducator* Panz. and the chalcid *M. vitripennis* Walk.

It was found that within a host-containing area *T. evanescens* is able to perceive its hosts (eggs of the Angoumois grain moth) by the sense of sight, but that it does not appear to perceive them at a distance by the sense of smell, although it is attracted to traces left by females of the Angoumois grain moth. "*Trichogramma* normally moves about in straight or widely curving lines with only occasional abrupt turns. On such a path, it finds its first host. When it leaves that host, however, or any host which it has parasitized or examined, it moves quite differently, taking a spiral, twisted path. This change of behavior greatly increases the frequency of contact between the parasite and its hosts."

It was shown by experiments that *A. manducator* and *M. vitripennis* are attracted to an environment likely to contain their hosts by qualities of the environment itself, independent of the presence of hosts. Evidence is adduced that several other parasites are likewise first attracted to a special type of situation, in which they then seek their hosts.

A list is given of 18 references to the literature.

The food of adult partridges (*Perdix perdix* and *Alectoris rufa*) in Great Britain, A. D. MIDDLETON and H. CHERRY (*Jour. Anim. Ecol.*, 6 (1937), No. 2, pp. 322-336, pls. 2, fig. 1).—An analysis made of the contents of the crops taken from 429 adult gray partridges (*P. perdix*) and 29 red-legged partridges (*A. rufa*), collected in all parts of Great Britain, is reported upon

in this contribution. It was found that the food eaten by the common gray partridge changes seasonally, being composed largely of seeds and grain in autumn and nearly all grass and green leaves in late winter and spring. Sugar beet pulp is eaten during winter. Flowers and buds form an important part of the food during summer. Animal food (mostly ants and their pupae) occurs in significant quantities only during the summer months. The food of the red-legged partridge is similar.

[Contributions on economic insects, insecticides, and insect control] (*U. S. Dept. Agr., Bur. Ent. and Plant Quar.*, 1938, E-451, pp. 42; E-452, pp. 7, pls. 3; E-453, pp. 174; E-454, pp. 5, pl. 1; E-455, pp. 16; E-456, pp. 3; E-457, pp. 28; E-458, pp. 3; E-459, pp. 3; E-460, pp. 12, pls. 2; E-461, pp. 6; 1939, E-462, pp. 5; E-463, pp. 221; E-464, pp. 22, pls. 2; E-465, pp. 3; E-466, pp. IX+145; E-467, pp. 25; E-468, pp. [1]+79).—The following contributions are in continuation of this series (*U. S. R.*, 80, p. 365); The Arsenates of Magnesium as Insecticides—A Review of the Literature, by F. E. Dearborn (E-451); Grasshopper Control by Tillage and Seeding Methods, by J. R. Parker (E-452); *Lonchocarpus* (Barbasco, Cube, and Timbo)—A Review of Recent Literature, by R. C. Roark (E-453); Combating the American Dog Tick, Carrier of Rocky Mountain Spotted Fever in the Central and Eastern States, by F. C. Bishopp and C. N. Smith (E-454); Legislation in the United States for the Control of Insects and Other Plant Pests, by L. A. Strong (E-455); Pyrethrum Larvicides for Mosquito Control (E-456); References to Reviews and Popular Articles on Derris, by R. C. Roark (E-457); Fumigation of Dormant Deciduous Nursery Stock for the Oriental Fruit Moth With Methyl Bromide, by L. A. Hawkins (E-458); Prevention of Insect Damage to Wind-Thrown Timber in the New England States, by F. C. Craighead (E-459); Technique and Equipment for Handling Two Hymenopterous Parasites [*Microgaster tibialis* Nees and *Eulimneria alkæ* Ell. and Sacht.] of the European Corn Borer, With Particular Reference to Prolonging their Hibernation, by K. D. Arbutnot and W. A. Baker (E-460); The Plant Quarantine Act and Quarantine No. 37, by L. A. Strong (E-461); The Gladiolus Thrips and Its Control, by R. H. Nelson and C. A. Weigel (E-462); A Digest of the Literature Through 1934 Relating to Insecticidal Spray Residues, by R. L. Busbey (E-463); Biology of the White-Fringed Beetle *Naupactus leucoloma* Boh., by H. C. Young and B. A. App (E-464), which supersedes E-420 (*U. S. R.*, 79, p. 369); Some Results of Recent Work With Dried-Fruit Insects, by P. Simmons, D. F. Barnes, C. K. Fisher, and G. H. Kaloustian (E-465); The Use of Fluorine Compounds as Insecticides—A Review With Annotated Bibliography, by R. H. Carter and R. L. Busbey (E-466); Chemicals and Methods Used in Treatments of Trees by Injections, With Annotated Bibliography, by R. H. Carter (E-467); and The History of the Use of Derris as an Insecticide—II, The Period 1919-1928, by R. C. Roark (E-468) (see page 244).

Review of United States patents relating to pest control, [January-December 1938], R. C. ROARK (*U. S. Dept. Agr., Bur. Ent. and Plant Quar., Rev. U. S. Pat. Relat. Pest Control*, 11 (1938), Nos. 1, pp. 9; 2, pp. 8; 3, pp. 14; 4, pp. 11; 5, pp. 10; 6, pp. 8; 7, pp. 10; 8, pp. 11; 9, pp. 9; 10, pp. 8; 11, pp. 10; 12, pp. 11).—A continuation of this series (*U. S. R.*, 78, p. 817).

Factors concerned in the deposit of sprays, V, VI. (Univ. Calif.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 57-69, figs. 5).—This continuation of the studies (*U. S. R.*, 80, p. 798) is presented in two parts.

V. The effects of pH upon the deposit of the oil and water phases of oil emulsions, G. T. Brown and W. M. Hoskins (pp. 57-61).—It was found that the deposit of oil upon a standard beeswax surface "from emulsions containing sodium

oleate or triethanolamine oleate is decreased by changing the pH from 2.5 to 7.5. Upon further changing the pH to 10 the deposit is greatly increased except when large amounts of the soaps are present. When hemoglobin is used, the oil deposit increases with pH throughout the range. With all three accessory substances the total amount of oil emulsion deposited increases as the pH rises. Attention is called to the importance of pH control in practical spraying."

VI. *The role of electrical charges produced during spraying*, E. L. WAMPLER and W. M. HOSKINS (pp. 61-69).—This work is in continuation of the earlier studies noted (E. S. R., 75, p. 224). "Electrical charges are produced on droplets by the rupture or atomization of liquid columns as well as by impact and splashing of droplets against a surface. The rolling of droplets and sliding of films of liquid over surfaces also produce charges thereon. . . . Spray droplet charge is directly proportional to spraying pressure and inversely proportional to electrolyte concentration. On sprayed beeswax surfaces charge varies greatly both in sign and magnitude, depending on kind and amount of electrolyte present and upon hydrogen-ion concentration of the spray. Wetting of the wax surface occurred when aluminum nitrate was present in certain concentrations in the spray suspension, but this wetting would not take place unless the pH of the solution was properly adjusted. A mechanism is suggested whereby aluminum ion operates to produce wetting. When wetting occurred, the magnitude of charge upon the sprayed surface decreased steadily as wetting progressed, and at complete film formation the charge always reached a minimum value. This charge-wetting relationship held for several wetters of widely divergent chemical composition. Deposit of lead arsenate is related to degree of wetting but not to charge upon spray droplets or sprayed surface. The results obtained when plant leaves were sprayed closely paralleled those with beeswax surfaces. Retention of lead arsenate upon the beeswax surface could not be increased by charging spray droplets and sprayed surface with external potentials of unlike sign, and wetting was likewise unaffected. Wetting controls deposit, and in its absence deposit is low. There is no relation between the deposit of lead arsenate, total charge of the spray droplets, nor total charge of the sprayed object."

Mechanical and other factors affecting oil spray deposits, G. S. HENSILL and V. J. TRENKO (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 36-40).—A discussion of mechanical and some other factors affecting spray deposits and data on the effects of some of these factors on deposits are presented. More oil per unit of area was deposited on natural surfaces than on artificial surfaces. By keeping close checks on the apparatus and other factors concerned with spray application, it was found possible to obtain close results in different tests.

Hydrocyanic acid gas in the vacuum fumigation of broom corn under winter conditions, L. S. McLANE and H. A. U. MONRO (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 94-98).—The work reported has shown that larvae of the European corn borer chilled for varying periods up to a maximum of 21 days at a temperature of 10° F. are still susceptible to vacuum fumigation with hydrocyanic acid gas provided they are warmed prior to treatment for a period of 24 hr. at a temperature of not less than 50°. "The commercial treatment of European broom corn based upon these findings calls for a dosage of 2.5 lb. of hydrocyanic acid gas per 1,000 cu. ft. of tank space acting in a sustained vacuum at an absolute pressure of approximately 2.5 in. of mercury for a period of not less than 3 hr. The commodity temperature required is one of not less than 60° in any part of the bales; the vault temperature is maintained at 80° to 90° with the aid of heating coils."

Basic copper arsenate: A new insecticide, I, II. (Ohio State Univ.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 142-146).—In the first part of this con-

tribution chemical and physical studies are reported by E. D. Witman, H. A. Waters, and E. F. Almy (pp. 142-144). In the second part insecticide and phytotoxicity studies are reported by H. A. Waters, E. D. Witman, and D. M. DeLong (pp. 144-146). The authors are led to recommend basic copper arsenate as a new insecticide-fungicide material. Its principal chemical and physical properties are described, and the results of tests with the Mexican bean beetle, Colorado potato beetle, southern armyworm, velvetbean caterpillar, fall webworm, and catalpa sphinx, with which it proved fully as effective as acid lead arsenate or calcium arsenate, are reported. "Basic copper arsenate has a slower initial effect and a more rapid final effect on the insects tested than lead arsenate. This property increases the chance that gross feeding insects will ingest a toxic dose before the poison causes feeding to cease. Because of its low soluble As_2O_3 value and its stability, basic copper arsenate is much safer on most types of plant foliage than are other commercial arsenicals. In basic copper arsenate the factor of lead and lead residues is eliminated and the copper factor is introduced, which gives the material decided promise as a fungicide."

The early history (1848-1918) of the use of derris as an insecticide, R. C. ROARK. (U. S. D. A.). (*Pests*, 6 (1938), No. 12, pp. 8-10).

Seasonal variation in the distribution of two species of Symphyla found in California, A. E. MICHELBAEHR. (Univ. Calif.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 53-57, figs. 6).—Population trends of *Scutigerella immaculata* (Newp.) and *Symphylella subterranea* Michelb., which have markedly different reactions, are considered.

Laboratory evaluation of soil poisons used in termite control, G. L. HOOKENYOS (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 147-149).—A description is given of a simple method of evaluating termite soil poisons. "Trichlorobenzene and polychloropentane are shown to be much superior to the orthodichlorobenzene now commonly recommended. Sodium arsenite and arsenate were the best of the inorganic compounds tried. Sodium pentachlorophenate is highly toxic and repellent, but seems to be easily removed from its water solution by the soil."

The common termite and the dry-wood termite in Puerto Rico [trans. title], G. N. WOLOORT, trans. by F. SEHN, JR. (*Puerto Rico Col. Sta. Bul.* 48 (1939), *Span. ed.*, pp. 26, figs. 13; *Eng. abs.*, p. 26).—Brief accounts are given of the only 2 of the 16 species of termites known to occur in Puerto Rico that have received popular names, namely, *Nasutitermes costalis* Holmg. (= *N. morio* Latr.), the common termite, popularly known as "comején," and *Cryptotermes brevis* Walk., the dry-wood termite, popularly known as "polilla." Mention is also made of *Heterotermes tenuis* Hagen and *H. convecinotatus* Snyder, also of economic importance in the island.

The regional and seasonal incidence of grasshopper plagues in Australia, K. H. L. KEY (*Austral. Council Sci. and Indus. Res. Bul.* 117 (1938), pp. 87, figs. 14, map. 1).—In this contribution all the available information regarding grasshopper plagues in Australia is brought together and presented as a history of the plagues, special attention being paid to the correct identification of the species involved and to seasonal and geographical distribution. The species of major economic importance, *Orthotermes terminifera* Walk., and *Austroicetes cruciata* Sauss., are first considered (pp. 13-75), followed by an account of the species of minor economic importance, namely, *Gastrimargus musicus* F., *Austacris guttulosa* Walk., *Phaulacridium vittatum* Sjöst., *Oedaleus australis* Sauss., *Locusta migratoria* L., *Brachyewarna lobipennis* Sjöst., and *Praxibulus laminatus* Stål. and *Urnisa* sp. and *Peakesia* sp.

A list is given of 66 references to the literature.

Problems of growth of the African migratory locust, A. J. DUARTE (*Bul. Ent. Res.*, 29 (1938), No. 4, pp. 425-456, figs. 12).—This account of the African migratory locust *Locusta migratoria migratorioides* (R. & F.) is presented with a list of 16 references to the literature.

Thrips of economic importance in California, S. F. BAILEY (*California Sta. Circ.* 346 (1938), pp. 77, figs. 40).—Following a brief introduction, general description of thrips, identification of species (including a key to those of economic importance in California), general biology and habits, distribution and injury, and control, summarized accounts are given of those of major importance in the State. Included are the pear thrips, California flower thrips *Frankliniella moultoni* Hood, bean thrips, citrus thrips, onion thrips, gladiolus thrips, greenhouse thrips, grape or vine thrips *Drepanothrips reuteri* Uzel, California toyon thrips *Rhynchothrips ilex* (Moulton), hollyhock thrips *Liothrips varicornis* Hood, lily thrips *L. vaneeklei* Pr., sugar beet thrips *Hercothrips femoralis* (Reut.), and the composite thrips *Microcephalothrips abdominalis* (Crawf.). Brief mention is made of several other species for which there are no common names in general use and which are of minor importance, occurring mostly on ornamentals and in greenhouses. Other thrips of economic importance in North America that do not occur in California are noted, and a selected list is given of references to the economic forms, arranged according to species.

The six-spotted thrips Scolothrips sexmaculatus (Perg.), S. F. BAILEY. (Univ. Calif.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 43-47, fig. 1).—An account is given of the economic importance, distribution, and taxonomic position, and a description of the stages of the six-spotted thrips *S. sexmaculatus*. This is one of the oldest species of thrips known to North America, but its life history has remained unknown.

Sprays control prune thrips, S. C. JONES. (Oreg. State Col.). (*Better Fruit*, 33 (1939), No. 9, pp. 3, 16, figs. 2).

The effect of thrips injury on production in cotton, R. K. FLETCHER and J. C. GAINES. (Tex. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 78-80).—The loss suffered in a field of cotton in the Brazos River Bottoms in Burleson County, Tex., severely injured by the flower thrips, was calculated to be 358 lb. of seed cotton per acre. Many of the plants were killed in this field. In 12 bottomland fields the estimated average loss was 107 lb. and in 2 upland fields 61 lb. Attack results in a smaller size of boll, a smaller number of bolls per plant, and late opening of the bolls.

Control of plant bugs in citrus groves, J. R. WARSON. (Fla. Expt. Sta.). (*Citrus Indus.*, 19 (1938), No. 10, pp. 12, 13).—A practical account.

Toxicity of hydrogen cyanide, chlorpicrin, and ethylene oxide to eggs, nymphs, and adults of the bedbug, H. GUNDERSON and A. L. STRAND. (Mont. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 106-110, figs. 3).—The variations among stages and among fumigants as used against the bedbug are shown in the experiments here reported. "No conclusions may be drawn as to the action of ethylene oxide and chlorpicrin on bedbug eggs. It is shown that hydrogen cyanide is from 2 to 48 times as toxic as the other gases used. Bedbug eggs are less resistant to hydrogen cyanide and ethylene oxide than are nymphs and adults. The eggs are apparently much more resistant to chlorpicrin than are nymphs and adults. Nymphs and adults of the bedbug are very similar in their reactions to the fumigants used in these experiments."

The glasshouse leaf-hopper, Erythroneura pallidifrons Edw., G. FOX WILSON (*Jour. Roy. Hort. Soc.*, 63 (1938), No. 10, pp. 481-484, pls. 2).—A dis-

cussion of the biology and control of *E. (Zygina) pallidifrons*, which has become of increasing importance as a pest of greenhouse plants in Great Britain in recent years.

Breeding areas and economic distribution of the beet leafhopper in New Mexico, southern Colorado, and western Texas, V. E. ROMNEY (*U. S. Dept. Agr. Circ. 518 (1939), pp. 15, figs. 3*).—Surveys made during the period extending from June 1928 to January 1936 have led to the location and mapping of breeding areas of the beet leafhopper that occur along the Rio Grande drainage in southern New Mexico and western Texas. A perennial mustard (*Lepidium alyssoides*) was found to serve as the host for from 85 to 90 percent of the first- and second-brood leafhoppers that move during May and June each season to infest distant agricultural districts east of the Continental Divide. These districts were separated into zones of infestation by using as a basis the degree of curly top infection found in sugar beets from 1928 to 1933. The degree of infestation to which these districts were subjected from year to year was found to vary with host plant conditions in the breeding area. Economic infestations by the leafhopper in fall and winter crops in the Mesilla Valley occurred only during fall seasons when there were practically no perennial or germinated mustard plants in the sandy foothills and when large leafhopper numbers resulted from favorable summer host conditions.

Field experiments for control of the beet leafhopper in Idaho, 1936–37, J. R. DOUGLASS, C. WAKELAND, and J. A. GILLET. (*U. S. D. A. and Idaho Expt. Sta.*). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 69–78, figs. 9).—Of the insecticides tested, pyrethrum was the only one found to be specific against the beet leafhopper. The results indicate that the 50:1 and 40:1 ratios of oil to pyrethrum are too large, and that best results were obtained at ratios of 25:1 and 30:1. "In general the percentage kill increased as the pyrethrum content increased. The percentage kill increased as the per-acre application increased from 5 to 6 to 7 to 8 gal. Disease counts showed no significant difference between the various treated and untreated plats. No correlation was found between the yield obtained and the spray applied. This was to be expected because the beet leafhoppers were found to redistribute themselves over the plats following each spray application. U. S. 12, a resistant variety to curly top, produced a fairly satisfactory yield under a very high degree of leafhopper infestation. The spring movement of this insect from the desert to the cultivated area extends over a period of from 12 to 36 days. The period of migration coincides very well with the seedling stage or the period of susceptibility of the plant."

The effect of temperature upon egg deposition, egg hatch, and nymphal development of *Paratrioza cockerelli* (Sulc), G. M. LISK. (*Colo. State Col.*). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 30–36).—Studies conducted during the winter of 1935–36 in an effort to measure the effect of certain temperatures and combinations of temperatures on the development of the several stages of *P. cockerelli*, the most serious pest of tomatoes and potatoes in Colorado, are reported, the details being given in tables.

Notes on the insect enemies of *Chermes*, with particular reference to *Pineus pini* Koch and *P. strobi* Hartig, F. WILSON (*Bul. Ent. Res.*, 29 (1938), No. 4, pp. 373–389).—The insect predators of pine *Chermes* are listed, and a brief account is given of the life history of the more important, particularly *P. pini* and *P. strobi*.

Time of fumigation of aphid infested canning peas and resistance of the plants to subsequent infestation, E. M. SEARLS. (*Univ. Wis.*). (*Jour.*

Econ. Ent., 32 (1939), No. 1, pp. 90-93, fig. 1).—Data presented indicate that normally aphid-susceptible canning peas become "uncongenial hosts to the aphids and cause them to start producing alate forms for migration at about the time that the peas come into blossom. When the aphid population is destroyed at this time, the naturally uncongenial nature of the peas inhibits the normal increase of aphid numbers on subsequent infestation. It is also indicated that, if the aphid infestation upon the peas is destroyed after the fourth week before the usual canning stage, the aphids will not have time to increase to destructive numbers before the peas are harvested for canning."

Hemipterous insects of cotton in Arizona: Their economic importance and control, T. P. CASSIDY and T. C. BARBER. (U. S. D. A.). *Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 99-104, fig. 1).—Notes are presented on some 15 species of hemipterous insects that feed and breed in Arizona on cotton plants and cause losses in quality and yield of lint. It is pointed out that many of the 53 species of Hemiptera met with in cotton fields of the State are apparently harmless and a few are beneficial as predators.

The silkworm and silk production (*Die Seidenspinner, ihre Zoologie, Biologie, und Zucht*. Berlin: Julius Springer, 1938, pp. VII+171, figs. 144).—Part 1 of this work, by F. Bock, deals with the zoology and biology of the silkworm (pp. 1-145) and part 2, by L. Pigorini, with silk culture (pp. 146-166).

Plutella maculipennis Curt., its natural and biological control in England, J. E. HARDY (*Bul. Ent. Res.*, 29 (1938), No. 4, pp. 343-372, pl. 1, figs. 10).—A brief introduction and a description of the life history and distribution of the diamondback moth are followed by an account of its biology and interrelation of its parasites in England and its natural control. Preliminary work with its natural enemies indicates that two parasites, *Angitia cerophaga* and *A. fenestralis*, constantly parasitize large numbers of the larvae. The collecting and breeding of these parasites for introduction into New Zealand is under way. A list is given of 16 references to the literature.

Laboratory studies of poisoned baits for the control of the southern armyworm, C. B. WISECUP and L. B. REED. (U. S. D. A.). (*Fla. Ent.*, 21 (1938), Nos. 3, pp. 38-47; 4, pp. 62, 63).—In laboratory work corn meal and cottonseed meal were found to be good substitutes for each other in southern armyworm baits. Lemon was found of no value; sirup definitely increased the effectiveness. The presence of natural food decreased the mortalities obtained with the baits, demonstrating the desirability of supplying this insect with an abundance of natural food when testing baits if the results are to be useful. Cryolite was the only poison that gave satisfactory results in any combination in the presence of natural unpoisoned food, with paris green second in effectiveness. Cube was worthless, while phenothiazine gave some mortality and in view of its safeness may be considered promising when used at a relatively high rate.

Insecticide tests for the control of the bollworm in 1936, R. W. MORELAND and J. C. GAINES. (U. S. D. A. and Tex. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 104-106).—Tests conducted indicate that "calcium arsenate, calcium arsenate plus paris green (5 and 10 percent), calcium arsenate plus cube (containing 0.8 percent rotenone), and calcium arsenate plus 50 percent sulfur were equally effective against the bollworm. All plats received calcium arsenate in the foregoing mixtures at the rate of 7.76 to 9 lb. per acre. When the rate of application of calcium arsenate was reduced to 7 lb. per acre, as in the calcium arsenate plus lime mixture, the yield was likewise reduced. Pyrethrum dust (containing 0.09 percent pyrethrins I and II) with sulfur as a carrier did not prove effective against these pests. These results agree with

previous reports concerning this problem, namely, that calcium arsenate applied at the rate of from 8 to 9 lb. per acre proved to be the most effective and economical insecticide for the control of the bollworm."

Control of the corn earworm on Fordhook lima beans in eastern Virginia, L. W. BRANNON. (Coop. Va. Truck Expt. Sta.). (*U. S. Dept. Agr. Circ.* 506 (1939), pp. 15, figs. 2).—The results of experiments conducted with the corn earworm from 1935 to 1938, inclusive, on the eastern shore of Virginia, where it frequently causes severe damage to the fall crop of Fordhook lima beans after corn in the vicinity has dried out and is no longer attractive to the moths for egg deposition, are reported. The damage is caused by the feeding of the earworm on the pod through the wall of which it makes a round hole and often completely devours the contents. This injury causes many of the young pods to shed and necessitates hand culling of the damaged pods prior to marketing the crop. The experiments have shown that this damage may be appreciably reduced by the application of "cryolite dusts or sprays, the former being applied either as an undiluted dust or at the rate of 60 parts to 40 parts of talc or sulfur by weight and the latter at the rate of 3 lb. in 50 gal. of water. It was found that in addition to giving a high degree of control of the insect on pods remaining on the plants at harvest, applications of these materials caused increases in the number of pods produced compared with the untreated plats, showing that injury and resultant shedding of young or immature pods was prevented. In order to secure thorough coverage of all parts of the plants the insecticide should be directed to both the upper and lower surfaces of the leaves. A bait composed of 1 lb. of cryolite to 25 lb. of corn meal, broadcast evenly over the leaves of the plants at the same time intervals as for dust or spray applications, is also effective for control of this insect on lima beans. Treatments should be begun when the majority of the silks on ears of field corn in the vicinity of late plantings of lima beans have dried out, or not later than such time as the lima bean plants under observation are in full bloom. Three or four treatments are usually necessary, depending on the abundance of the insect. In order to avoid the danger of harmful fluorine residues on the edible portions of the market product treatments should be discontinued 2 weeks prior to harvest." The results of analyses of samples of shelled beans following treatment with cryolite talc dust have shown the grains of fluorine present per pound to come in most cases within the tolerance limit established for fluorine on fruits. With canned lima beans the grains of fluorine per pound present were well below the tolerance established for fluorine on fruits, indicating that the ordinary washing process in the commercial canning of the crop effectively removes harmful fluorine residues deposited through outside agencies.

Inactivation of pyrethrum after ingestion by the southern armyworm and during incubation with its tissues, P. A. WOLFE. (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 4, pp. 289-295).—An investigation aimed at determination of the reason for the inactivity of the toxic principles of pyrethrum and their resulting failure to act when ingested by the southern armyworm is reported. To this end pyrethrum was fed to the larvae in turnip-leaf sandwiches, and later the tissues, gut contents, and feces were ground and tested against mosquito larvae for the presence of toxic principles. In order to determine the kind of tissues that might be responsible for such inactivation the pyrethrum was mixed with the various tissues and the gut contents from healthy larvae and incubated at 29° C. in the dark for 18 hr. Half of the material was agitated during incubation, and the material was then tested against mosquito larvae for the presence of toxic principles. The results indicate that the toxic principles of pyrethrum

may become inactivated, wholly or in high degree, after ingestion by the southern armyworm. The tissue of the digestive tract and the gut contents may reduce the toxicity of unextracted pyrethrum little or none, and of extracted pyrethrum only partially. The blood may have little or no effect on the toxicity. The skin and muscle tissues may greatly reduce the toxicity of agitated extracted pyrethrum, but only partially reduce the toxicity of unagitated extracted pyrethrum and of either unagitated or agitated unextracted pyrethrum. The fat body may reduce the toxicity of unextracted pyrethrum partially and of extracted pyrethrum greatly, even when these materials are not agitated, but the toxicity of both when agitated with fat body during incubation may be very greatly reduced.

A list is given of 15 references to the literature cited.

The European corn borer assumes increased importance, G. E. R. HERVEY and L. A. CARRUTH (*Farm Res. [New York State Sta.]*, 5 (1939), No. 2, pp. 6, 11, figs. 3).—With the gradual spread of the two-generation form of the European corn borer during the past 8 or 9 yr. from New England, where it was discovered 20 yr. ago, westward into New York State, where the one-generation form was found about the same time as the New England infestation, this pest has mounted in importance. Long Island and the Hudson Valley as far north as Saratoga and Schenectady Counties have become areas of severe infestation in the State, which include approximately 15,000 acres of sweet corn. Traces of the two-brooded form in the vicinity of Syracuse and in parts of Oswego and Jefferson Counties were reported during the season of 1938. In the area of severe infestation in eastern New York during the season 1938 much of the early sweet corn harvested in July was worthless because of borer injury. Many of the fields were from 80 to 100 percent infested and 10 or more borers were frequently found per plant. Medium early corn was relatively free from injury, while late corn or that harvested after the first of September was about as seriously infested as the early corn. Control work now under way includes the introduction of parasites, breeding of resistant varieties of corn, and the development of insecticides. It was found in 1938 that powdered derris root containing 5 percent rotenone used at the rate of 4 lb. to 100 gal. of water with a suitable spreader gave very good control. "Four to five treatments were necessary to protect the rapidly growing corn plants during the egg-laying season. The treatments were distributed over a period beginning when the first eggs started to hatch and extending until shortly after egg laying reached a peak. Certain fixed nicotine dusts and sprays also reduced borer population but were less efficient than the derris spray." The importance of community cooperation in clean-up practices, which include disposal of corn remnants by plowing or burning, is emphasized.

Occurrence and responses of a partial second generation of the European corn borer in the Lake States, A. M. VANCE (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 83-90, fig. 1).—Investigation has revealed an increase in recent years in the proportion of the European corn borer producing two generations annually in southeastern Michigan, northwestern Ohio, and northeastern Indiana. In the 10 counties of northeastern Indiana surveyed in the fall of 1937, 28 percent of the larvae observed were sufficiently immature to indicate they belonged to a second generation, and as high as 8.7 percent of the larvae in early sweet corn surveyed in the vicinity of Toledo in the summer of the same year pupated late in July and early in August and produced moths which deposited their eggs during August. This recent noticeable occurrence of a partial second generation in the Lake States is considered to be the result of cumulative climatic influences rather than the more immediate weather effects of any single season in itself.

Toxicity to the codling moth larva of derivatives of benzene containing halogen and nitro groups, E. H. SIEGLER, F. MUNGER, and L. E. SMITH. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 129-131).—The results of tests of halogenated benzenes, nitrobenzene, monohalogenated nitrobenzenes, dihalogenated benzenes (except difluoro), and dinitrobenzenes and of initial and residual tests of *p*-iodonitrobenzene against the larva are reported in detail in tables. Among the derivatives tested "*p*-iodonitrobenzene, *m*-iodonitrobenzene, *p*-bromonitrobenzene, and *m*-dinitrobenzene gave an initial toxicity of less than 50 percent of wormy plugs. In residual tests *p*-iodonitrobenzene lost most of its effectiveness in 5 or 6 days. The data obtained indicate no marked correlation between either the groupings involved or their relative position with regard to their toxicity to the codling moth larva."

Hybridization experiments with *Anopheles maculipennis*, M. BATES (Amer. Jour. Hyg., 29 (1939), No. 1, Sect. C, pp. 1-6).—The results of crosses of *A. maculipennis*, made in all cases with *A. atroparvus* males, are reported.

Pyrethrum and oils for protection against salt-marsh sand flies (Culicoides), J. B. HULL and S. E. SHIELDS. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 93, 94).—The results of laboratory and practical tests have shown the following to be the most effective combinations for ridding sand flies from houses: One part pyrethrum extract concentrate (20 to 1) and 20 parts lubricating oil (S. A. E. 5) or 1 part pyrethrum extract concentrate (20 to 1), 6 parts kerosene, and 12 parts lubricating oil (S. A. E. 10). "These combinations should be evenly and thoroughly applied to the door and window screens with a brush or rag. The rooms should then be well sprayed with standard pyrethrum extract spray, such as is commonly employed against flies and mosquitoes, to kill sand flies already inside."

The introduction into Puerto Rico of beneficial insects to aid in the control of the horn fly of cattle, K. A. BARTLETT (Puerto Rico Sta. Agr. Notes No. 88 (1939), pp. 6).—As an aid in the control of the horn fly, which is a serious pest of cattle and horses on the south coast of Puerto Rico, several of its natural enemies have been introduced into the island. These include a number of species of dung beetles, which destroy the breeding places of the horn fly, and a hymenopterous parasite, *Spalangia philippinensis* Full., from Hawaii, which attacks the puparia. The dung beetles introduced are *Canthon pilularius* and *Phaenus triangularis* from Texas and *Copris incertus prociudus* and *Onthophagus incertus* from Hawaii.

Mention is also made of several native parasites of the housefly and stablefly reared from field-collected hornworm puparia, namely, *Spalangia muscidarum* Rich., *Ashmeadopria* n. sp., *Pachycrepoideus dubius* Ashm., and *Muscidifurax raptor* Gir. and Sand.

The olfactory responses of flies in a new type of insect olfactometer.—II, Responses of the housefly to ammonia, carbon dioxide, and ethyl alcohol, J. O. G. WIERING and W. M. HOSKINS. (Univ. Calif.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 24-29, fig. 1).—In this further contribution (E. S. R., 72, p. 367) an olfactometer suitable for use with houseflies is described. "It depends upon streams of air heated to 41° C. to attract the flies to the test and check areas. Concentration of the substance to be tested is controlled by the use of flowmeters and saturating chambers. The results show that mixed groups having a sex ratio of approximately unity are attracted to ammonia at a concentration of 0.012 percent by volume but are strongly repelled at concentrations greater than 0.03 percent. Carbon dioxide has no appreciable effect up to about 2 percent. Ethyl alcohol attracts feebly at 0.012 percent and repels

above about 0.05 percent. With separated sexes, females are more strongly attracted than males to ammonia and the reverse is the case with ethyl alcohol."

The larvae of *Agromyzinae* [trans. title], J. C. H. DE MEIJERE (*Tijdschr. Ent.*, 80 (1937), No. 3-4, pp. 167-243, figs. 94; 81 (1938), No. 1-2, pp. 61-116, figs. 60).—A continuation of the account previously noted (*E. S. R.*, 73, p. 358).

A new method of feeding adult horn flies (*Haematobia irritans* L.) and stable flies (*Stomoxys calcitrans* L.), W. G. BRUCE and C. EAGLESON. (U. S. D. A.). (*Jour. Kans. Ent. Soc.*, 11 (1938), No. 4, pp. 144, 145, fig. 1).—A description is given of a rapid, inexpensive, and satisfactory method of feeding horn and stable flies that has been developed. It consists in providing blood in glass tubes and the utilization of the insects' positive phototropism.

[Contributions on the apple fruit fly], F. H. LATHROP (*Maine State Pomol. Soc. Ann. Rpt.*, 1934-35, pp. 12, 13, 38-41).—Contributions on The Apple Fruit Fly Problem (pp. 12, 13) and Investigation of the Apple Fruit Fly, 1935 (pp. 38-41) are presented.

The feather-legged fly, H. E. BRATLEY. (Fla. Expt. Sta.). (*Citrus Indus.*, 19 (1938), No. 9, pp. 13, 14).—A brief account of a tachinid parasite of plant bugs of economic importance in Florida.

Further fly parasites of *Dysdercus*, C. H. T. TOWNSEND (*Rev. Ent.*, 8 (1938), No. 3-4, pp. 347, 348).—Four species of dipterous parasites of cotton stainers in Brazil are described as new under the names *Paraphoranthia politana*, *Alophoropsis brasiliensis*, *Euphorantha dysderci*, and *Phoranthella mendesi*.

A nutritional study of the larva of *Dermestes vulpinus* F., F. J. GAY (*Jour. Expt. Zool.*, 79 (1938), No. 1, pp. 93-107, figs. 4).—It has been found that the hide beetle, which normally feeds on foods of high protein content, can be reared from the egg to adult stage on a diet of casein, cystine, cholesterol, yeast and salts, or yeast, cholesterol, and salts. Cholesterol is essential for normal growth. Vitamin B (undifferentiated complex) also appears to be necessary. The salts contained in brewers' yeast are satisfactory for growth. The hide beetle can develop on low concentrations of cystine.

Control of the flatheaded apple tree borer in Oklahoma, G. V. JOHNSON and F. A. FENTON. (Okla. A. and M. Col.). (*Jour. Econ. Ent.*, 52 (1939), No. 1, pp. 134-142).—The findings in control work with the flatheaded apple tree borer in Oklahoma are summarized as follows:

"Results from stomach poisons tested indicate that heavy applications of arsenical sprays are necessary to obtain good kills of the adult. Because of the activity of the beetles, it is believed spraying a small area will not protect trees. Repellent paints applied to growing apple trees reduced the number of parasitized borers by 33 percent. A method of testing repellent mixtures by exposing cuttings in trees frequented by the adult borers was devised. Walnut cuttings were more heavily infested with borers than apple cuttings exposed at the same time. Creosote, paradichlorobenzene, and carbolic acid were injurious to the bark of apple and walnut. Paraffin alone gave nearly as good repellence as paraffin and paradichlorobenzene, and did no injury to the wood. Most promising repellents are carbolineum preparations, paraffin, and a naphthalene-flour-soap preparation. Materials tried as fumigants to kill the borer in the larval stage were ineffective. Protecting trees with a paper wrap materially reduced the number of trees killed by borers, but when wraps were applied to the trunk the beetles shifted their attack to the limbs above the wrap. Paper wraps rotted away near the ground and needed attention at this point, especially when the trees were watered frequently."

Wireworm damage to potatoes in the Yakima Valley of Washington, K. E. GIBSON. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 121-124, fig. 1).—In the studies reported it was shown that wireworm injury to potatoes is in a general way related to the number of wireworms in the soil, although other factors than numerical abundance of these pests may have considerable effect on their depredations. "No definite forecast of the damage that may be incurred can be made on the basis of wireworm population, but it seems that with a population of 0.5 wireworm per square foot approximately 25 percent of the crop may be damaged. The injury will rise with increasing numbers of wireworms until after six or seven wireworms per square foot are found, when the added damage may be relatively little."

Trapping elaterid beetles as a control measure against wireworms, R. E. CAMPBELL and M. W. STONE. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 47-53, figs. 2).—Attempts to trap adults of elaterid beetles led to the conclusion that piles of plant material to provide traps for *Limonius californicus* cannot be used successfully as an aid in its control, at least not under conditions existing in southern California.

Larval development of the native elm bark beetle (*Hylurgopinus rufipes* (Eich.)) in Massachusetts, W. B. BECKER. (Mass. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 112-121, figs. 13).—It appears from the count made of cast larval skins in several galleries of the native elm bark beetle that there may be a variation in the number of stadia of this pest. "The results obtained, however, by plotting on graphs the size distribution of the head widths of one generation of larvae which were collected at approximately weekly intervals indicate that five stadia occurred most commonly under the conditions of the experiment. The results also indicate an overlapping in the sizes of the head widths of successive larval instars and allow for a variation from this number of instars for some of the larvae. In addition, because the species is monogamous and the sexes are almost equal in number and because there is a difference in the size distribution of the head widths of the male and female adults, the data suggest the possibility that a difference in size distribution due to sex may begin to become noticeable in the last two instars. The possibility of such a difference in size, however, is not determined by this experiment. Evidence of a more definite nature is required."

Effect of sun-light and of location of logs on the beetle infestations of elm logs, C. H. MARTIN. (Cornell Univ.). (*Bul. Brooklyn Ent. Soc.*, 33 (1938), No. 4, pp. 195-201, pls. 2).—It was found that *Hylurgopinus rufipes* (Eich.) and *Scolytus multistriatus* Marsham infestations in logs in a ladderlike arrangement and of logs suspended 35 to 40 ft. above the ground did not differ significantly, indicating that both species infest logs near the ground as readily as those high above it. "*H. rufipes* infestations of the logs of these two experiments did not differ significantly from those of the check logs which were 3 ft. off the ground and in less sunlight than the logs of the experiments, and it was inferred that the *H. rufipes* infestation depends to a greater extent upon the proximity of the log to the hibernating quarters of this species. On the other hand, when *H. rufipes* infestation was low, *S. multistriatus* infestations of the experimental logs did differ significantly from those of the check logs, indicating that an increase in sunlight caused a corresponding increase in the infestation of this species. The clearing of trees around a deep-shade station so as to increase the amount of sunlight falling on the logs brought about a marked increase in *S. multistriatus* infestation."

The native elm bark beetle (*Hylurgopinus rufipes* (Eichhoff)) in Connecticut, B. J. KASTON (*Connecticut [New Haven] Sta. Bul.* 420 (1939), pp. 39, figs. 19).—The results of work reported in earlier contributions by the author

(E. S. R., 76, pp. 64, 224; 77, pp. 75, 813; 79, p. 359; 80, p. 81) and later findings on the life history and habits of the native elm bark beetle, which is of importance as a disseminator of the causative fungus of Dutch elm disease and much more abundant in the State than the smaller European elm bark beetle, are first presented, the details being given in tables and figures. The natural factors of control and the associated fauna are then considered, followed by a brief summary and a bibliography of 41 references.

Studies in population physiology.—VIII, The effect of larval population density on the post-embryonic development of the flour beetle *Tribolium confusum* Duval, T. PARK (*Jour. Expt. Zool.*, 79 (1938), No. 1, pp. 51-70, figs. 3).—A further contribution in this series of studies (E. S. R., 78, p. 82).

Notes on the biology of the cotton pruner *Chalcodermus bondari* Marshall, L. PYENSON (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 80-83, figs. 4).—Report is made of observations of the biology of this cotton pest, which has been found damaging the crop throughout the State of Pernambuco, Brazil, and as far south as the Chaco region in Argentina.

Biology and control of the pea weevil in the Palouse area of Idaho and Washington, T. A. BRINDLEY. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 21-24).—Observations of the biology of the pea weevil and experiments on control measures in the Northwest are briefly reported. The results suggest that further "research on the relationship between the blossoming dates of the border and main field, on the type of plowing equipment used to bury the peas, and the use of insecticides in connection with the borders may make the use of border trap strips a valuable adjunct in pea weevil control."

A new species of *Calliephialtes* from Brazil, with a key to the Neotropical species (Hymenoptera: Ichneumonidae), R. A. CUSHMAN. (U. S. D. A.). (*Rev. Ent.*, 9 (1938), No. 1-2, pp. 11-13).—A parasite of the pink bollworm in São Paulo, Brazil, is described as new under the name *C. dimorphus*. A table for the identification of the seven species of this genus is included.

Suggestions for the control of sawflies on conifers, E. I. MoDANIEL (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 3, pp. 161-164, figs. 2).—Practical suggestions are given for the control of sawflies on conifers, particularly the larch sawfly, Abbott's sawfly *Neodiprion pinetum*, the red-headed pine sawfly, and the introduced pine sawfly.

The black widow spider and its parasites, W. D. PIERCE (*Bul. South. Calif. Acad. Sci.*, 37 (1938), No. 3, pp. 101-104, figs. 3).—A scelionid hymenopteron found to parasitize the egg balls of the black widow spider on the sand dunes at El Segundo, Los Angeles County, Calif., is described as *Baeus californicus* n. sp. Nine of the 38 egg balls collected in cactus clumps on the dunes were parasitized by this new species. Of the 2,420 eggs in the 9 balls 98.55 percent were attacked by this parasite.

Pear bud injury and the pear leaf blister mite, J. F. LAMTMAN. (Univ. Calif.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 40-43).—Studies of the biology and means of control of the pear leaf blister mite are reported. The habits of the bud form of this mite, which causes considerable losses in the pear-growing sections of California through winter destruction of fruit buds, are very different from the blister form, although no structural differences have been found. In some sections, especially in the Sierra foothills, harvest is so delayed that control measures cannot be applied before many of the mites have worked deep into the buds. In these areas the addition of 5 lb. of wettable sulfur to the early codling moth sprays was found to provide an adequate check on the activities of the bud form of the pear leaf blister mite.

Observations on the nature of bulb mite attack on Easter lilies, R. LATTA (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 1, pp. 125-128, figs. 5).—Investigations commenced in 1935 of the bulb mite, which tunnels the stems of Easter lily bulbs at the ground level causing them to lean or break at that point, are reported. In this work the mites failed to produce this injury even though it is often found in commercial practice. It was demonstrated that infestations of this mite are probably present in all lots of Easter lily bulbs. A definite association between mite injured stems and lack of stem roots was observed in thousands of lily plants. The work indicates that an unknown plant disorder is primary to mite injury on stems.

Eriophid studies, II, H. H. KEMER (Calif. Dept. Agr. Bul., 27 (1938), No. 3, pp. 301-325, figs. 18).—This contribution supplements that previously noted (El. S. R., 80, p. 236), with descriptions of 18 additional mites, 14 of which are new to science. A generic key to the Phyllocoptinae incorporates the two new genera proposed in this article, namely *Colepitrimerus* and *Caliphytoptus*.

ANIMAL PRODUCTION

[Livestock investigations in California] (*California Sta. [Bien.] Rpt.* 1937-38, pp. 60-67).—Studies for which results are briefly reported include the value of supplemental feeding of range cattle; the effect of maintaining pregnant heifers on very low protein rations; the effect of phosphorus deficiency in beef cattle rations; the value of stock beets for fattening lambs; the vitamin B requirements of hogs; the vitamin A requirements of hens; the requirements of poultry for various members of the vitamin B complex, vitamin K, and the anti-gizzard-erosion factor; the value of orange peel and pulp meal, chocolate meal, babassu meal, cull beans, and hempseed meal for poultry; the mode of inheritance of factors influencing egg production in chickens and turkeys; a comparison of various types of turkey rations; and the effect of fish oils and fish meals on the flavor of turkey flesh.

[Livestock investigations in Delaware], A. E. TOMHAVE (*Delaware Sta. Bul.* 214 (1938), pp. 14-19).—Progress reports (El. S. R., 78, p. 518) are briefly noted for the following studies: Dried distillers' and dried brewers' grains for growing fattening pigs, the value of forage crops for pigs, breeding poultry for high egg production and viability, with special reference to the methods of selecting males, protein levels in the rations of growing chicks, broiler production, and the value of artificial light for White Leghorn pullets.

[Experiments with livestock in Florida], A. L. SHEALY, W. G. KIRK, R. M. CROWN, R. B. BECKER, W. M. NEAL, P. T. D. ARNOLD, L. L. RUSOFF, R. W. KIDDER, W. F. WARD, M. E. HAMMOND, L. O. GRATZ, C. H. WILLOUGHBY, N. R. MEHRHOF, and M. W. EMMEL. (Partly coop. U. S. D. A. et al.). (*Florida Sta. Rpt.* 1938, pp. 62, 63, 64, 65, 66, 67, 68-72, 170-172, 173, 176-178, 181, 194, 195, 196-198).—Brief progress reports (El. S. R., 78, p. 519) are presented for the following lines of investigation: The value of purebred sires of various breeds mated to native cows for grading up beef herds and other beef and dual-purpose cattle; mineral deficiencies in feeds used in cattle rations; the feeding value of crotalarinas; the efficiency of the trench silo for the preservation of Florida forage crops; the digestibility and feeding value of dried citrus refuse; the comparative value of sugarcane silage, shocked sugarcane, and pasture when supplemented with cottonseed meal or cake for wintering beef cattle; the value of broken ear corn, corn-and-cob and shuck meal, velvetbeans in the pod, ground velvetbeans, and blackstrap molasses in steer fattening rations; the value of Napier grass for pasture purposes; comparative wool production of native, grade Hampshire,

and grade Columbia sheep; the deficiencies of peanut meal when used as a feed for swine; the utilization of citrus meal as a swine feed; and a comparison of various grazing crops for fattening feeder pigs.

From poultry investigations results are noted on breeding for increased livability and egg production, the vitamin content of shark-liver oil, the utilization of citrus byproducts for poultry, egg production and mortality of pullets reared under confinement v. range conditions, the importance of range rotation, the comparative efficiency of different types of brooder stoves, rations for feeding layers in batteries, and the use of peanut products for turkey rations.

[Livestock investigations in South Dakota], J. W. WILSON, B. AUNE, and W. E. POLEY (*South Dakota Sta. Rpt. 1938, pp. 13-16, 17-22, 40-47*).—Studies on which data are given include a comparison of protein supplements for fattening cattle, the use of sugar beet byproducts in lamb fattening rations when corn and barley were each fed as the principal grain, a comparison of rations for breeding ewes, a comparison of corn, heavy-weight, medium-weight, and light-weight barleys, and ground oats for fattening summer pigs, corn v. ground cane seed for fattening fall pigs, forage crops for spring pigs after weaning, the effect of pasture crop utilization by swine on the quality and palatability of pork, a comparison of high and lower grades of grain in poultry rations, and the relative values of the common grains and their effect on poultry carcass quality, the utilization of corn, wheat, oats, and barley in turkey rations, factors affecting hatchability of turkey eggs, capon production, and the value of millet grains in growing and fattening rations.

[Livestock investigations in Washington] (*Washington Sta. Bul. 368 (1938), pp. 23-25, 28, 29, 67-70*).—Progress results are briefly reported for the following studies (E. S. R., 79, p. 372): The value of cull peas in cattle feeding rations, by H. G. McDonald and H. Hackedorn; the nutritive value of fresh crested wheatgrass and of sweetclover hay, both by J. Sotola; rations for ewes, by Hackedorn and H. P. Singleton; alfalfa meal v. sweetclover meal for bred gilts and the nutritive value of second-year sweetclover forage, both by McDonald; meat storage in community cold-storage lockers, by Hackedorn and W. Burkitt; the protein requirements of laying hens and of chicks, the protein value of various concentrates, fish byproducts in poultry rations, the nutritive requirements of turkeys, and the vitamin requirements of poultry, all by J. S. Carver, E. I. Robertson, J. L. St. John, and J. W. Cook; the effect of heredity and environment on interior egg quality and the effect of storage conditions on egg quality, by L. A. Wilhelm and Carver; the pH of watery white in eggs, by St. John; and the light requirements of laying hens, by Carver and H. L. Garver.

The nutritive values of some forage crops of Puerto Rico.—II, Legumes, grasses, and a mixture, J. H. AXTMAYER, G. RIVERA HERNÁNDEZ, and D. H. COOK (*Jour. Agr. Univ. Puerto Rico [Col. Sta.], 22 (1938), No. 4, pp. 455-481*).—Continuing this line of investigation (E. S. R., 79, p. 668), the digestibility and biological value of Yaraguá and Merker (elephant) grasses and of soybeans and velvetbeans, each in the bloom and full-pod stages, and pigeonpeas in the pre-bloom stage, were determined in trials with sheep. The data are recorded in detail. The Yaraguá grass proved the least palatable of the various crops studied. The biological value of the proteins of the various legumes ranged from an average of 38 for soybeans in the bloom stage to 63 for soybeans and velvetbeans in the full-pod stage as compared with 84 for Yaraguá grass. The coefficient of digestibility of the different nutrients averaged higher and the nutritive ratio was much narrower for the legumes than for the Yaraguá. The pigeonpeas showed the highest fattening value of all the legumes studied, while the value of Merker grass was far below that of any of the legumes.

The nutritive values of Indian cattle foods and the feeding of animals, K. C. SEN (*Imp. Council Agr. Res. [India], Misc. Bul. 25 (1938), pp. [1]–39*).—This publication presents information on the chemical composition, digestibility, and nutritive value of a wide variety of Indian feeding stuffs.

Sweet clover silage, F. W. CHRISTENSEN (*North Dakota Sta. Bimo. Bul., 1 (1939), No. 4, pp. 6–8*).—General recommendations for the preparation of silage from sweetclover and from other legumes, grasses, and cereals are set forth. The results of a preliminary trial at the station indicated that the addition of 70 lb. of beet molasses per ton of green clover resulted in a well-preserved silage which was readily consumed by sheep.

The nutritive value of dried tomato pomace, W. B. ESSELEN, JR., and C. R. FELLERS. (Mass. Expt. Sta.). (*Poultry Sci., 18 (1939), No. 1, pp. 45–47*).—Assays of dried tomato pomace indicated the following vitamin potencies: Vitamin A, 6.8 International Units per gram; vitamin B₁, 8.7 Chase-Sherman units per gram, equivalent to about 4 I. U. per gram; vitamin B₂ (G), 3 Bourquin-Sherman units per gram and 2.8 Cornell chick units per gram; and vitamin C, 1.4 I. U. per gram. These data indicate that this material is a good source of vitamin B₁ and a fair source of vitamins A and B₂.

The vitamin A content of dried citrus pulp, M. C. FUTCH, L. L. RUSOFF, and R. B. BECKER. (Fla. Expt. Sta.). (*Jour. Dairy Sci., 22 (1939), No. 2, pp. 115, 116, fig. 1*).—Bio-assay of dried citrus pulp (largely from grapefruit canneries) indicated that this product contained less than 0.5 U. S. P. units of vitamin A per gram.

Stability of carotene in green grasses and alfalfa stored at five degrees Fahrenheit, D. W. BOLIN. (Idaho Expt. Sta.). (*Jour. Dairy Sci., 22 (1939), No. 2, pp. 111–113*).—Samples of green alfalfa, Kentucky bluegrass, orchard grass, meadow fescue, and bromegrass collected at intervals during the month of July were analyzed for carotene in the fresh state and after storage in the dark at 5° for 10 mo. The alfalfa showed a pronounced loss of carotene during storage (average loss 62.7 percent in one and 70 percent in another), while the grasses stored under like conditions lost little or no carotene, suggesting that a carotene-destroying factor active at 5° was present in alfalfa but not in the grasses.

The effect of different methods of drying on the biological value and digestibility of the proteins and on the carotene content of grass, S. BARTLETT, K. M. HENRY, S. K. KON, L. W. OSBORNE, S. Y. THOMPSON, and J. TINSLEY (*Biochem. Jour., 32 (1938), No. 11, pp. 2024–2030*).—In an experiment at the National Institute for Research in Dairying, the biological value and true digestibility were determined for the proteins of respectively, artificially dried grass (300°) as 67 and 66, for artificially dried grass (170°) 62 and 65, and for sun-cured grass 52 and 64. The differences in the biological value of proteins from artificially dried grasses and hay were highly significant, while other differences were not. Samples of the grass artificially dried at high temperature, at low temperature, and in a current of hot air, sun-cured, and dried without sun at air temperature contained 86.7, 78.1, 89.4, 25, and 31.5 percent, respectively, as much carotene as found in the fresh grass.

A comparative study of the metabolism of certain amino acids, with special reference to respiratory exchange and heat production, M. KRIS. (Pa. Expt. Sta.). (*Jour. Nutr., 17 (1939), No. 1, pp. 1–14, fig. 1*).—In a series of balance experiments with male albino rats, four groups of animals received a low nitrogen basal diet supplemented with 2.06 gm. of *D*-glutamic acid, 1.75 gm. of *D*-alanine, and 2.4 and 1.8 gm. of glycine per animal daily, respectively. These levels of amino acids supplied 7.5, 7.5, 7.4, and 5.6 kg. calories

of gross energy, respectively. The metabolizable energy of the glutamic acid was found to be 80.8 percent of its gross energy, that of alanine 65.68, and that of glycine 64.53 and 67.54 percent at the higher and lower levels. A comparison of these data with those previously presented for certain proteins (E. S. R., 78, p. 520) indicated that the proteins were more completely metabolized than were the single amino acids.

Lactic acid formation by muscles of scorbutic guinea pigs, O. RAHN. (Cornell Univ.). (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 2, pp. 334-336).—When excised muscles from guinea pigs showing severe scorbutic symptoms were suspended in phosphate buffer containing glucose, about one-half as much lactic acid was produced as by comparable muscle tissue from normal rats, indicating that scurvy had caused a pronounced injury of this enzyme complex. The addition of ascorbic acid directly to the minced muscle had no effect, either in normal or scorbutic muscle, upon the rate or final amount of lactic acid produced.

A study of glycine toxicity, A. R. PATTON. (Univ. Ark.). (*Poultry Sci.*, 18 (1939), No. 1, pp. 31-34, fig. 1).—Glycine proved toxic to chickens when the level of ingestion reached a certain point, 1 gm. per day being fed for an extended period without symptoms of toxicity, while 4 gm. per bird daily caused toxicosis within a few days. When 25 gm. of glycine suspended in water was introduced into the crop of a hen, coma and frequently death resulted within 24 hr. Glycine toxicity was not due to high intake of soluble organic matter or soluble nitrogen, as evidenced by the fact that 30 gm. of either glucose or urea were easily tolerated. Other qualitative tests indicated that it was not due to oxalic acid, methylamine, acidosis, alkalosis, or increased glycine in the blood. The probable cause was an excessive intake of soluble amino nitrogen, since identical toxicity was observed when similar amounts of *DL*-alanine were administered. Symptoms of toxicosis were accompanied by a marked increase in urinary nitrogen, a pronounced decrease in liquid excretion, an increase in concentration of purines, and an increase in size of kidneys with accompanying damage.

The stability of vitamins A and D in mixed feed ingredients.—I, Vitamin D, F. D. BAIRD, A. T. RINGROSE, and M. J. MACMILLAN (*Poultry Sci.*, 18 (1939), No. 1, pp. 35-39).—When fortified cod-liver oil was mixed in the chick ration and stored at summer room temperature, assays conducted after 2, 4, 8, 12, 16, and 32 weeks of storage failed to indicate any measurable destruction of vitamin D.

Estimation of the antihæmorrhagic vitamin, H. J. ALMQUIST, E. MECCHI, and A. A. KLOSE. (Univ. Calif.). (*Biochem. Jour.*, 32 (1938), No. 11, pp. 1897-1903, fig. 1).—Continuing this line of investigation (E. S. R., 78, p. 377), it was found that the blood clotting time of the chick varies with age, the vitamin K reserve of the chick, and the vitamin K content of the ration. It tended to reach a maximum at 2 weeks of age, while at 3 weeks of age the chick achieved a balance of blood clotting power with respect to the vitamin K content of the ration. The reciprocal of the blood clotting time was found to be a simple linear function of the logarithm of the vitamin K level in the ration, over a practical range of values. An improved assay technic for vitamin K based on these findings is described.

Continuous grazing at Invershiel, H. MACRAE ([*Wilmington, N. C.: Author*, 1938, pp. 15, figs. 6]).—This booklet describes the use of a succession of annual crops which have provided year-round grazing for cattle under conditions prevailing in eastern North Carolina.

An experiment in beef production in western Canada, A. M. SHAW and J. W. G. MACLEWAN (*Sci. Agr.*, 19 (1938), No. 4, pp. 177-198, figs. 9).—This experiment was initiated in 1930 with 40 cows each of the Galloway, Shorthorn, Hereford, and Aberdeen Angus breeds. All cows were mated to Angus bulls the first year, Herefords the second, Shorthorns the third, and Galloways the fourth, so that purebreds and crossbreds of each group were available for comparison. The Galloway bulls withstood the hardships of the range much better than the other breeds, followed in order by the Herefords, Angus, and Shorthorns. There was little difference in the fertility or in the depreciation due to death and sterility for the four groups of cows. Calves from the Angus cows averaged heaviest at weaning time, followed in order by Shorthorns, Herefords, and Galloways. No single breed or cross was outstanding in feedlot performance, the Galloway breed consistently making the poorest showing. The crossbreds had a definite advantage over the purebreds in rate of gain and quality of carcass. Reciprocal crosses produced cattle of similar color markings and of about equal quality and utility. Heifer calves of all breeds finished about 30 days earlier than steer calves. Data are reported on an experimental shipment of chilled beef to Great Britain, indicating that this practice offers certain great advantages but that further investigation is needed to overcome many obstacles before such trade could be established.

Wintering steers on different planes of nutrition from weaning to 2½ years of age, W. H. BLACK, J. R. QUESENBERRY, and A. L. BAKER. (Coop. Mont. Expt. Sta.). (*U. S. Dept. Agr., Tech. Bul.* 667 (1939), pp. 20, figs. 5).—Experiments were conducted at the U. S. Range Livestock Experiment Station, Miles City, Mont., comparing the total gains and feed costs of steers from weaning time to approximately 2½ yr. of age when weaned on three different planes of nutrition. The average gains per steer during the 193 days of winter feeding were 169, 93, and 39 lb. Average gains during the 485 days on summer and fall range were 477, 522, and 571 lb., and total feed and range costs per 100 lb. of gain were \$3.11, \$2.20, and \$1.78 for steers on the high, medium, and low planes, respectively. Thus, while significantly greater gains were attained by steers wintered on a high plane of nutrition, significantly cheaper gains and greater gains during the grazing season were made by steers wintered on the low plane of nutrition.

Cardiovascular and other lesions in calves fed diets low in magnesium, L. A. MOORE, E. T. HALLMAN, and L. B. SHOLL. (Mich. Expt. Sta.). (*Arch. Path.*, 26 (1938), No. 4, pp. 820-838, figs. 7).—Calves used in previously described experiments (*E. S. R.*, 73, p. 673), which developed a tetany due to magnesium deficiency in the diet, were further investigated for histopathological symptoms. The principal pathological alterations consisted of a deposition of calcium salts in the yellow elastic fibers of the endocardium, of the aorta, jugular vein and larger arteries, of the surfaces of the diaphragm, and of the trabeculae and capsule of the spleen. Degeneration and calcification of the Purkinje fibers were also noted, along with various degrees of inflammation of the liver and kidneys. A possible relationship of low magnesium intake to arteriosclerosis of human beings is suggested.

The sugar and total ketone content of the blood of ewes and of their new-born lambs, L. C. SNOOK and W. GODDEN (*Biochem. Jour.*, 32 (1938), No. 11, pp. 2037-2039).—In a study at the Rowett Research Institute, blood samples from normal and ketonemic ewes prior to and shortly after lambing and from newborn lambs were analyzed for sugar and total ketones. A marked rise in blood sugar level at parturition was noted in both normal and hypoglycemic ewes, with some evidence that post partum there is a fairly rapid return to

the normal level. Hypoglycemia in the pregnant ewes was reflected in a much lower blood sugar level at parturition and lower blood sugar in the newborn lambs than for normal ewes. The blood of the newborn lamb contained a higher sugar level than that of its dam bled at the same time. Newborn lambs from ketonemic ewes showed complete freedom from ketone bodies in their blood.

The influence of cobalt on pine disease in sheep, H. H. CORNER and A. M. SMITH (*Biochem. Jour.*, 32 (1938), No. 10, pp. 1800-1805).—The Edinburgh and East of Scotland College of Agriculture secured evidence that the pine disease of sheep, which is prevalent in the Cheviot region of Scotland, is a nutritional anemia which is not due to a deficiency of iron, copper, or manganese and which can be cured or prevented by the administration of cobalt salts. The administration of 1 mg. of cobalt per head daily for 14 days proved sufficient to prevent the disease for 6 mo. when sheep were confined to land commonly producing this disorder. A similar dosage was also effective as a cure.

[The progress of swine improvement in Canada] (*Sci. Agr.*, 19 (1938), No. 3, pp. 138-176, pl. 1 figs. 2).—The following listed papers were presented before a symposium held in Ottawa in June 1938 at the annual meeting of the eastern section of the Canadian Society of Animal Production: Advanced Registry For Pure Bred Swine, by A. W. Peterson (pp. 139-142); Test Station Operation, by R. G. Knox (pp. 143-146); Results of Station Testing in Canada, by J. G. Lefebvre (pp. 147-154); The Analysis and Interpretation of Hog Carcass Data, by E. W. Crampton (pp. 155-161); A Study of Factors Influencing Swine Carcass Measurements, by J. G. Stothart (pp. 162-172); and The Market Value of Canadian Bacon, by L. W. Pearsall (pp. 173-176).

Fish meal for bacon hogs, S. A. HILTON (*Sci. Agr.*, 19 (1938), No. 3, pp. 121-137).—This report from the Dominion Experimental Farm, Nappan, N. S., briefly summarizes the results of a series of feeding trials comparing whitefish meal with skim milk, tankage, and other supplements as a source of protein for bacon hogs. On the basis of average daily gains, feed required per unit of gain, and carcass grade, the fish meal compared very favorably with the other supplements tested. A bibliography of 152 references is appended.

Transit shrinkage of fasting pigs ([*Gt. Brit.*] *Bacon Devlpmt. Bd. Bul.* 3 (1938), pp. 36, figs. 2).—The transit shrinkage of groups of pigs shipped by rail from distances ranging from 33 to 300 miles and lasting from 1½ to 42 hr. was studied. The decrease in carcass weight of fasting pigs during transit was found to progress at a rather constant rate, averaging approximately 3 lb. per head per 24-hr. period. This loss was greater in the trimmed sides than in the head, backbone, feet, and other bony parts of the carcass, indicating that the tissue wastage occurred mainly in the muscular and/or fatty tissues, probably due to abnormal water losses from such tissues. The duration of transit did not appreciably affect the conformation or quality of the carcass, its suitability for tank curing, or the net yield of tank bacon per 100 lb. of carcass weight. There was a tendency for an increase in thickness of the flank with increasing length of the transit period. Pigs moved by fast carrier lost less than pigs fasted for the same period and moved over the same distance by slower train.

25 years' stallion enrollment in Indiana (*Indiana Sta. Circ.* 240 (1938), pp. 52, figs. 14).—A brief résumé of the activities of the Indiana stallion enrollment board over the past 25 yr. is presented, along with a directory of enrollments and renewals issued from January 1 to December 31, 1938, classified by counties (*M. S. R.*, 79, p. 378).

The meat requirements of fox vixens during the reproductive period, C. F. BASSETT. (U. S. D. A.). (*Amer. Fur Breeder*, 11 (1939), No. 8, p. 10).—A comparison of the reproduction records of groups of vixens maintained on rations containing 40 and 60 percent of raw meat, respectively, indicated that the former is fully as desirable as the latter.

Breeding for poultry viability, D. R. MARBLE (*Pennsylvania Sta. Bul.* 377 (1939), pp. [2]+38, figs. 8).—A 5-yr. program of selection of breeders from the most viable families of Single Comb White Leghorns and Barred Plymouth Rocks has resulted in improved viability in the rearing flock and a 50-percent reduction in mortality in the laying flock, with only a slight decrease in chick viability. Greater viability of adult birds was obtained among birds hatched from eggs produced by hen breeders than from those by pullet breeders. Definite family differences were established in the extent to which resistance to the fowl paralysis complex developed. Subsequent laying flock mortality of 5-month-old pullets showing gray-eye condition was considerably greater than for pullets possessing normal eyes. Laying flock mortality was distributed rather uniformly over the laying year. Increased viability was obtained without significant losses in egg production, egg size, age at sexual maturity, and body weight.

Influence of fattening foodstuffs and temperature on the fowl's body fat [trans. title], T. TAKITA (*Bul. Sci. Fakult. Terkult., Kjušu Imp. Univ., Fukuoka, Japan.*, 8 (1938), No. 1, pp. 1-15; *Eng. abs.*, pp. 14, 15).—When one-half of the ration of fattening fowls was variously supplemented by ground Italian millet, ground corn, ground great millet, soybean hulls, wheat flour mixed feeds, and ground buckwheat over a 30-day fattening period, no significant differences were found in the physical or chemical characters of the body fat as a result of the ration. A comparison of fowls fattened in winter (average temperature 5° C.) and in summer (average temperature 27°) indicated that the body fat of the former contained only about one-fourth as much free fatty acid but more liquid fatty acid than that of the latter. Reichert-Meissl, Polenske, iodine, and thiocyanogen values were all materially higher at the winter temperature. From these facts it is inferred that animals placed in a disadvantageous environment require relatively unstable compounds for their preservation.

Fluctuations of phosphatase and inorganic phosphorus in the blood of the laying hen during the period of egg formation, W. J. PETERSON and D. B. PARRISH. (*Kans. Expt. Sta.*). (*Poultry Sci.*, 18 (1939), No. 1, pp. 54-58).—Blood samples from hens which had been laying for 9 mo. and from pullets which had just come into lay, collected immediately after and at approximately 12 and 26 hr. after oviposition of the previous egg, were analyzed for phosphatase and inorganic phosphorus. In the former group the average plasma phosphatase was 30 percent higher and the inorganic plasma phosphorus 15 percent higher at the time of active shell deposition than at the start of the 20-hr. egg cycle. In the latter group there was an increase of 35 percent in phosphatase and 39 percent in inorganic phosphorus at the period of active shell deposition. The possible role of phosphatase in eggshell formation was discussed.

Phosphatase and inorganic phosphorus in the plasma and whole blood of the fowl, W. J. PETERSON and D. B. PARRISH. (*Kans. Expt. Sta.*). (*Poultry Sci.*, 18 (1939), No. 1, pp. 59-62).—The average plasma phosphatase values of 5-month-old cockerels and pullets were found to be 20 and 22.9 units, respectively, while corresponding values in the whole blood were 16.5 and 17.2 units. For birds of corresponding breed and sex at 16 weeks of age the plasma contained 8.8 and 9.7 units and the whole blood 7.8 and 10.4 units, respectively.

There was no significant difference in the inorganic phosphorus content of the plasma and whole blood in either sex.

The effect of resecting the so-called "chalaziferous region" of the hen's oviduct on the formation of subsequent eggs, B. R. BURMESTER and L. E. CARD. (Univ. Ill.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 138-145, fig. 1).—In an effort to obtain additional information on the mechanism of chalaza formation in eggs, 31 hens were surgically altered by the removal of sections of the oviduct from 2 to 7 cm. long from the chalaziferous region of the infundibulum. Of the 25 hens surviving the operation, 12 laid normal eggs, and dwarf or yolkless eggs were laid by 19. Some laid nothing but yolkless eggs, others laid dwarf eggs alternately with normal eggs, and 7 laid one or more yolkless eggs when first coming into production and only normal eggs thereafter. With 9 hens laying a sufficient number of normal eggs after the operation to allow a comparison of pre- and postoperative eggs, there was no significant change in the weight of the chalaza, total egg weight, or proportions of the egg white layers, even though the percentage of the chalaziferous region removed ranged from 44 to 88. A normal-appearing chalaza in the inner thin white surrounded by a thick firm white layer was found in most of the dwarf eggs. The correlation between the weight of the chalaza and that of the inner thin white was lower in the yolkless eggs than in the normal ones.

A comparison of dry milk, meat and bone meal, and combinations of both as protein supplements for egg production and a critique of methods, E. W. HENDERSON. (Iowa Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 106-113).—Employing the all-mash method of feeding, the influence of eight different protein supplements on the egg production of White Leghorn pullets and hens was measured by three different statistical procedures. The various supplements included dried milk at 15, 10, and 5 percent levels, meat-and-bone meal at 10 and 5 percent levels, and combinations of dried milk and meat-and-bone meal at 5 and 5, 9 and 5, and 5 and 8 percent levels. An analysis of variance of the average annual egg production (October 1 to September 30) of pullets failed to show any significant differences between the various pens. However, when the October production records were omitted and the production records for the remaining 11 mo. were similarly analyzed, significant differences appeared. When yearling hens were distributed among the pens with respect to the previous year's production, highly significant differences were obtained by the three methods of calculation. The average egg production (11 mo.) was 152, 139, and 121 eggs, and the percentage production per hen days was 45, 42, and 37 for the milk, the combination, and the meat-and-bone meal groups, respectively.

The effect of certain mineral salts on the amount and severity of perosis, R. M. SHERWOOD. (Tex. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 165-167).—In a comparison of the effect of eight experimental rations on the incidence of perosis in chicks, it was found that the basal diet containing 9 p. p. m. of manganese, 420 p. p. m. of aluminum, 98 p. p. m. of iron, 1.41 percent of calcium, and 0.72 percent of phosphorus gave very poor protection against this disorder. Increasing the aluminum and iron content of the diet only slightly improved the degree of protection. Substituting 20 percent of wheat gray shorts for an equal amount of milo in the diet increased the total manganese to 21 p. p. m. and afforded almost complete protection, as did the addition of 37 p. p. m. of manganese to the basal diet. Adding the ash of 20 percent of wheat gray shorts to the diet was less effective than when this amount of shorts was incorporated in the diet.

The amount of manganese required to prevent perosis in the chick, W. D. GALLUP and L. C. NORRIS. (Cornell Univ.). (*Poultry Sci.*, 18 (1939), No. 1, pp. 76-82).—When New Hampshire chicks were reared on a low manganese basal diet, perosis developed in approximately 80 percent of the cases. When the manganese content of the diet was increased to 50 p. p. m. by additions of chemically pure $MnCl_2$, $MnSO_4$, $KMnO_4$, $MnCO_3$, and MnO_2 , the incidence of perosis was reduced to about 4 percent, with evidence that these various salts were equally effective. In trials to determine the minimum amount of manganese required to prevent perosis, graded levels of manganese intake from 20 to 100 p. p. m. were provided by additions of $MnCO_3$. A level of 30 p. p. m. completely prevented perosis in White Leghorns, while 50 p. p. m. reduced perosis to 7 percent in a normal strain of New Hampshires and to 18 percent in a highly susceptible strain of New Hampshires, thus indicating breed differences. A diet containing 1,000 p. p. m. of manganese was fed over a period of 20 weeks with no toxic effect.

The effect of a deficiency of manganese in the diet of the hen, W. D. GALLUP and L. C. NORRIS. (Cornell Univ.). (*Poultry Sci.*, 18 (1939), No. 1, pp. 83-88).—Groups of New Hampshire pullets were fed rations containing 13, 53, 200, 500, and 1,000 p. p. m. of manganese, respectively. As the manganese intake increased over this range the manganese content of the eggs progressively increased from 0.045 to 0.342 mg. per 100 gm. of dry yolk. The lower level of manganese intake resulted in low egg production and high mortality of embryos, with such deaths generally occurring late in the incubation period. Production was slightly lower, but hatchability was as good at the 53 p. p. m. level of intake as at the higher levels. The minimum manganese requirement of the developing embryo was found to be about 0.005 mg., which represented approximately 70 percent of the manganese in the egg. Chicks hatched from low-manganese eggs and having a low initial manganese reserve were no more susceptible to perosis than those hatched from high-manganese eggs.

Beryllium rickets in chickens, H. D. BRANTON, F. F. TISDALL, and T. G. H. DRAKE (*Poultry Sci.*, 18 (1939), No. 1, pp. 66-69, figs. 4).—In tests by the Ontario Agricultural College et al., the growth and bone development of chicks receiving a normal ration and others receiving a similar diet supplemented with 0.5, 1, and 2 percent beryllium carbonate were compared. The chicks tolerated 0.5 percent over the 10-week experimental period with no evidence of rickets or abnormal bone development, but those receiving the 1 and 2 percent levels developed beryllium rickets as evidenced by low levels of inorganic plasma phosphorus, subnormal percentages of ash in the leg bones, and poor bone calcification. Individual birds varied somewhat in their response to the higher levels, but, in general, chickens are deemed more resistant to beryllium rickets than are rats.

Cereals and rickets.—IX, The availability of phytin-P to the chick, J. T. LOWE, H. STEENBOCK, and C. H. KRIEGER. (Wis. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 1, pp. 40-44).—Continuing this series of studies (E. S. R., 78, p. 577), chicks were fed a low-calcium, low-phosphorus basal diet variously supplemented with calcium carbonate, disodium phosphate, phytin, and cod-liver oil, involving 15 combinations in all. The addition of phytin in sufficient quantities to increase the phosphorus content of the basal diet 50 percent did not improve the calcification of the bones of chicks, while addition of an equivalent amount of phosphorus as disodium phosphate raised the bone ash approximately 10 percent. Additions of calcium carbonate or cod-liver oil did not significantly influence the utilization of phytin phosphorus. The point is stressed that cal-

cium: phosphorus ratios may be poor criteria of the proper mineral balance of a ration, since total phosphorus needs bear no relation to available phosphorus.

The effect of chondroitin sulfuric acid on gizzard erosion and growth in chicks, L. A. CRANDALL, JR., F. F. CHESLEY, R. E. GRAY, and H. E. ROBINSON (*Jour. Nutr.*, 17 (1939), No. 1, pp. 53-61).—A series of tests was conducted with chicks to determine the growth-promoting and gizzard-erosion-preventing activity of both commercial and purified chondroitin sulfuric acid when added at 3-percent levels to a commercial chick mash and to three different types of basal diets used by other investigators to experimentally produce gizzard erosions. No evidence was obtained to indicate that either preparation exerted any specific protective action against gizzard erosions. Under certain conditions they did exert a favorable effect on growth, leading to the suggestion that any slight influence upon gizzard erosion might be the result of a general nutritional improvement rather than the action of a specifically protective substance.

The production of goiter in chickens, A. R. PATTON, H. S. WILGUS, JR., and G. S. HARSHFIELD. (Colo. Expt. Sta.). (*Science*, 89 (1939), No. 2303, p. 162).—The production of experimental goiter in chicks by feeding a ration containing 0.145 mg. of iodine per kilo and the prevention of goiter by the addition of 5 mg. of iodine per kilo to the same ration are reported. Thyroid weights of chicks fed the basal diet were 130, 240, and 294 percent of those of the control group at 6, 12, and 18 weeks of age, respectively. The histopathological conditions of the enlarged thyroids are described.

The determination of vitamin A in the hen's egg, C. A. BAUMANN, J. SEMB, C. E. HOLMES, and J. G. HALPIN. (Wis. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 1, pp. 48-53).—Vitamin A was determined in eggs from White Leghorns which had received varying amounts of sardine or cod-liver oils as supplements to a standard poultry ration for 7 mo. Spectrophotometric determinations on egg yolks indicated a range from 5.4 μ g. of vitamin A per gram for those birds on a sardine-oil diet to 9.2 μ g. for those birds on a diet containing 2 percent cod-liver oil. Eggs from birds receiving 1 percent sardine oil and 0.5 and 2 percent cod-liver oil were incubated, and the newly hatched chicks were assayed colorimetrically or placed on a low vitamin A diet and allowed to succumb to the effect of the deficiency. The vitamin A content of the chicks, as well as the period of their survival, varied with the amount of vitamin A in the yolk, satisfactory agreement being obtained for the 3 technics. Four μ g. of vitamin A in the yolk extended the life of the chick for 1 day.

Breed differences in resistance to a deficiency of vitamin B₁ in the fowl, W. F. LAMOREUX and F. B. HUNT. ([N. Y.] Cornell Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 4, pp. 307-316, figs. 2).—In each of four experiments comparing chicks of the White Leghorn and Rhode Island Red breeds, the former showed a greater ability to survive on diets deficient or lacking in vitamin B₁ than the latter. Chicks of the White Leghorn and Rhode Island Red breeds survived an average of 12.9 and 10.8 days, respectively, when fed the deficient basal diet from hatching, 22.1 and 16.9 days when similarly treated except that they received an adequate diet on the third day only, and 34.1 and 29 days, respectively, when fed a normal diet to 2 weeks of age and the deficient diet thereafter. When chicks were fed a normal diet to 3 weeks of age and a deficient diet thereafter the percentages of chicks surviving to 13 weeks of age were 32, 20.5, and 8 for the White Leghorns, Rhode Island Reds, and Barred Plymouth Rocks, respectively. The superior resistance of the Leghorns to this deficiency was shown to be independent of body size and was not caused by differential mortality from other causes than polyneuritis. F₁ progeny of a Leg-

horn male \times Rhode Island Red females were intermediate between the parent strains in resistance to this vitamin deficiency.

The effect of the level of protein intake on the growth and feed utilization of turkeys, J. C. HAMMOND and S. J. MARSDEN. (U. S. D. A.). (*Poultry Sci.*, 18 (1939), No. 1. pp. 11-18, figs. 7).—Seven lots of Bronze turkeys, totaling 1,379 individuals, were reared to 28 weeks of age on poor grass range with ad libitum feeding of both mash and grain. The mash rations varied in protein content from about 18 to 30 percent by 2-percent increments. Mortality, malformation of legs or breastbones, and quantity of feed required per unit of gain were not significantly affected by either the protein content or calcium and phosphorus contents of the mash. During the first 16 weeks the average live weight of the lots was approximately in the same order as the quantity of protein fed. Birds fed the 28-percent mash weighed the most at all ages after 12 weeks, attaining an average weight of 15 lb. in 164 days, while birds receiving the 18-percent mash weighed the least at all ages and reached a 15-lb. average in 188 days. Under ad libitum feeding the birds ate more grain and less mash as the protein content of the mash increased, although the protein intake was not stabilized until the protein content of the mash reached 26 to 30 percent. The birds receiving the 18-percent mash were the most efficient on the basis of total protein and of animal protein required per pound of gain. Between 21 and 28 weeks of age the protein consumption of all groups was approximately the same, averaging about 16 percent.

Artificial incubation of some upland game birds' eggs, A. L. ROMANOFF, G. BUMP, and E. HOLM (N. Y. State Conserv. Dept. and Col. Agr. Bul. 2 (1938), pp. 44, figs. 9).—These studies were conducted to determine the optimum environmental conditions applicable to the practical incubation of pheasant, grouse, and quail eggs and to establish recognizable symptoms by which the cause of unsuccessful hatches might be determined. When the agitated-air-type incubator with separate hatcher was used, an incubation temperature of 99.5° F. and a relative humidity of from 63 to 68 for pheasants and from 60 to 65 for grouse and quail during the first 20 days of incubation proved most satisfactory. After the twentieth day a slight decrease for both in the case of quail eggs proved desirable. Higher incubation temperatures were required in the still-air-type than in the agitated-air-type machines. Turning eggs from 3 to 4 times a day and incubating them in a horizontal position are recommended. Other practical suggestions are outlined.

DAIRY FARMING—DAIRYING

Proceedings [of the] twenty-fourth annual meeting, western division, American Dairy Science Association (*Amer. Dairy Sci. Assoc., West. Div., Proc. Ann. Mtg.*, 24 (1938), pp. [3]+92, figs. 6).—The following listed papers are published in full in the proceedings of the meetings held at Portland, Oreg., October 2, 1938 (E. S. R., 79. p. 96): Some Experiences With Idaho Cooperative Bull Associations, by D. L. Fourn and I. H. Loughary (pp. 17-22) (Univ. Idaho); The Fertilization of Irrigated Pastures, by I. R. Jones, H. P. Ewalt, and J. R. Haag (pp. 30-34) (Oreg. State Col.); The Dry Matter Consumption of Holstein Cows on Roughage Rations, by J. C. Knott and R. E. Hodgson (pp. 35-38) (Wash. State Col.); A Comparison of Nutrient Requirements With Nutrient Consumption by Cows on All Roughage Rations, by R. E. Hodgson and J. C. Knott (pp. 39-43) (U. S. D. A., Wash. State Col., and West. Wash. Expt. Sta.); Variations in Reproductive Efficiency of Dairy Cattle, by A. Spielman and I. R. Jones (pp. 44-49) (Oreg. State Col.); Acid Values and

Acid Ratios as Related to the Keeping Quality of Salted Butter, by H. A. Bendixen (pp. 50-60) (Wash. State Col.); The Magnitude of the Volume Change Accompanying Water Sorption in Dry Milk Solids, by E. L. Jack (pp. 61-67) (Univ. Calif.); A Study of the Seasonal Changes in the Properties of Milk Fat From an Alfalfa Feeding Area of Eastern Oregon, by R. E. Stout and R. W. Stein (pp. 68-75) (Oreg. State Col.); and The Influence of Lighting Conditions on the Accuracy of the Babcock Milk Test, by D. R. Theophilus and D. C. Barnett (pp. 76-79) (Univ. Idaho).

[Experiments with dairy cattle and dairy products in California] (*California Sta. [Bien.] Rpt. 1937-38, pp. 98-100*).—Findings are briefly described on the effect of heat on dairy cows, methods of preventing off-flavors in milk, and improved methods for the manufacture of casein.

[Experiments with dairy cattle and dairy products in South Dakota], T. M. OLSON (*South Dakota Sta. Rpt. 1938, pp. 26-30*).—Records of dairy cattle investigations include the comparative returns from sweetclover, alfalfa, Sudan grass, and permanent pasture mixtures, the effect of direct sunlight on the growth, reproduction, and production of dairy cattle, the influence of fineness of grinding grains on the coefficients of digestion on dairy cows, the effect of vitamin D deficiency on mature dairy cows, the influence of roughages on the vitamin D potency of milk, and the relative efficiency of dairy breeds in transferring and converting vitamin D in the feed to milk.

Studies with dairy products include the relationship between the lipolytic and proteolytic micro-organisms in butter and the development of specific flavor defects, and the bacterial content and keeping quality of butter after removal from cold storage.

[Investigations with dairy cattle and dairy products in Washington]. (Partly coop. U. S. D. A.). (*Washington Sta. Bul. 368 (1938), pp. 30-36*).—Progress reports of dairy cattle studies (E. S. R., 79, p. 382), by R. E. Hodgson, J. C. Knott, H. K. Murer, R. R. Graves, E. L. Overholser, and K. Baur, include the nutritive value of home-grown hay and silage rations and of alfalfa hay rations for milking cows, a comparison of roughages alone v. roughages and limited amounts of concentrates for dairy cattle, methods of measuring pasture returns, the effect of type of construction on the losses and nutritive value of stack silage, the effect of apples in the ration on milk production, and the proving of dairy sires.

Reports of dairy products studies, by H. A. Bendixen, C. C. Prouty, E. V. Ellington, N. S. Golding, E. C. McCulloch, Murer, and G. H. Farrah, include the correlation of cream quality with butter quality; the manufacture, ripening, and development of foreign varieties of cheese; the gas requirements of certain strains of *Penicillium roqueforti*; bacterial development in milk from udder quarters infected with mastitis; and chemical factors affecting the quality of dried milk solids for baking purposes.

Live weight and milk-energy yield in the Wisconsin dairy cow competition, W. L. GAINES. (Ill. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 1, pp. 49-53, figs. 2).—A report by Brody and Cunningham (E. S. R., 75, p. 831) indicated that the gross efficiency of milk production in cows is independent of live weight. In a further analysis of the same data the author has shown that the milk-energy yield per unit of live weight is also independent of live weight. From the above findings it has been deduced that the feed energy required for working maintenance is proportional to live weight. The point is stressed that in considering the genetics of milk yield in dairy cows a distinction should be made between the size of the animal which may be measured by live weight

and proclivity to lactation which may be measured by milk-energy yield per unit of live weight.

The level of inorganic phosphorus in the blood of dairy cattle, S. R. JOHNSON. (Pa. Expt. Sta.). (*Jour. Nutr.*, 17 (1939), No. 1, pp. 15-21).—Data are presented on the inorganic phosphorus content of the whole blood of over 200 cattle, mostly cows and heifers, in normal health and nutrition. Values for immature cattle decreased with advancing age in an approximately regular manner, averaging from 6.42 mg. per 100 ml. for calves under 7 mo. to 4.7 mg. for calves from 25 to 30 mo. of age. There was relatively little difference in the values for milking cows at younger ages, but aged cows showed significantly lower values than middle-aged ones. No influences of breed or type of roughage fed on the blood phosphorus values were observed, and the effect of the level of milk production was questionable. Average values for milking cows, dry cows, and all cows were 4.28, 4.35, and 4.29 mg., respectively.

Calcium, phosphorus, and magnesium requirements in the nutrition of lactating cows, C. W. HOLDAWAY. (Va. Expt. Sta.) (*Va. Acad. Sci. Proc.*, 1938, p. 63).—Mineral balance trials with milking cows indicated that as the alfalfa hay intake was increased to provide large excesses of calcium there was a progressive increase in the calcium in the excreta above the increased amounts fed until a point was reached where the calcium in the excreta exceeded the amount ingested. Widening the calcium:phosphorus ratio by feeding excessive amounts of calcium did not affect the utilization of phosphorus. Monosodium phosphate as a supplement caused marked elimination of phosphorus in the excreta so that no phosphorus was retained for maintenance or productive purposes.

Observations on specific nutritional factors in lactation, S. J. FOLLEY, E. W. IKIN, S. K. KON, and H. M. S. WATSON (*Biochem. Jour.*, 32 (1938), No. 11, pp. 1988-1999, fig. 1).—In the first experiment described, female rats were fed a basal ration of ground rice, purified casein, butter, salt mixture, and yeast, either alone or supplemented with fresh liver, liver extract, or additional yeast, through gestation and lactation periods. Most of the rats on the basal diet nursed and weaned a high percentage of their young, and the performance of the rats on the supplemented diets was in no way superior to the ones on the basal ration. In a second trial, whitefish muscle meal replaced the casein in the basal diet. A high percentage of the rats on this diet nursed their young normally with good resulting growth. Stock colony rats which failed to rear their first litters proved more likely to lose their second litters than those which had successfully reared their first litters. The subcutaneous implantation of pig pituitary tissue into such rats after the second parturition had no influence on their ability to raise their young. No evidence was obtained to indicate the existence of specific dietary factors stimulating lactation which are qualitatively different from those normally required by nonlactating individuals.

The site of fat synthesis in the mammary gland, P. L. KELLY and W. E. PETERSEN. (Minn. and Ark. Expt. Stas.). (*Jour. Dairy Sci.*, 22 (1939), No. 1, pp. 7-16, figs. 5).—The results of three lines of investigation are summarized. Attempts to trace the course of milk fat synthesis by giving the cows feed heavily stained with Sudan IV gave entirely negative results. In all cases the fat in the alveolus was unstained. Biochemical analyses of 10 mammary glands from cows in various stages of lactation indicated the presence of quite large quantities of free fatty acid in the actively secreting glands, while resting glands contained much smaller amounts and glands undeveloped by pregnancy contained only a trace of free fatty acid. Histochemical studies with various

stains to differentiate between free fatty acid and neutral fat indicated the presence of free fatty acid in the secretory cells of the mammary gland, particularly in their basal portion, while neutral fats were concentrated near the distal portions of the alveolus. The free fatty acids did not occur as particles but apparently were present in the molecular or colloidal state.

Studies in the secretion of milk fat, I, II (*Biochem. Jour.*, 32 (1938), No. 10 pp. 1856-1876, figs. 6).—Two parts of this investigation are noted.

I. *The effect of inanition on the blood lipoids of the lactating cow*, J. A. B. Smith.—Using the same experimental cows previously described (*E. S. R.*, 81, p. 100), it was found that over a 12-day fasting period only slight decreases occurred in the lipid levels in the corpuscles, whereas reductions of from 40 to 50 percent occurred in the lipid content of the plasma, and this low level persisted even 6 weeks after liberal feeding was resumed. No appreciable change was noted in the nature of the lipoids in either the corpuscles or plasma as a result of fasting. Only fractional amounts, if any, of water-soluble fatty acids were present in the nonphosphatide fraction of the plasma of lactating cows.

II. *The effect of inanition on the yield and composition of milk fat*, J. A. B. Smith and N. N. Dastur.—As previously noted, the fat content of the milk increased sharply, but a steady decline in total fat secretion occurred, with advance of the fasting period. A marked change in the composition of the butterfat was noted, characterized by oleic acid largely replacing the lower acids up to and including C_{14} . The probable significance of this phenomenon is discussed. A modified procedure for the analysis of butterfat by fractional distillation is described.

Carotene balance and blood-carotene levels in heifers and lactating dairy cows, and their relation to the production of off-flavor milk, C. H. WHITNAH, W. J. PETERSON, F. W. ATKESON, and H. W. CAVE. (Kans. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 53 (1939), No. 5, pp. 343-355).—Spectrographic carotene determinations were made on the rations, blood, and feces of groups of dairy heifers and lactating cows receiving various types of rations to provide carotene intakes ranging from 0.003 to 2.51 mg. per kilogram of body weight. With two groups of heifers on a straw-molasses-cottonseed meal basal ration, one group receiving silage ingested about 5 times as much carotene but excreted only 3.2 times as much as the nonsilage group. The carotene content of the blood and feces of cows was extremely variable, with average blood serum levels ranging from 0.027 to 1.42 mg. per 100 ml., and the percentage of ingested carotene in the feces ranging from 75 to 1,470. The response of cows and heifers to carotene supplement following various feeding regimes suggested that feeding histories for several months may be an important consideration in tests involving carotene metabolism. Low carotene intake was regularly associated with milk susceptible to the development of oxidized flavor, while high carotene levels prevented or remedied this condition. It appeared that the optimum level of carotene intake was many times greater than the minimum required to prevent recognizable deficiency symptoms.

[Dairying experiments in New York] (*New York State Sta. Rpt. 1938*, pp. 11, 16, 17).—Results are briefly noted for the following studies: Methods of improving the quality of certain surface-ripened cheeses, the importance of mastitis in relation to the sanitary production of market milk, effect of plane of nutrition on milk flavor, and the practicability of the phosphatase pasteurization test.

Milk losses in milk plants are an important problem, A. C. DAHLBERG (*Farm Res. [New York State Sta.]*, 5 (1939), No. 2, pp. 9, 10).—A survey of milk

losses occurring in a number of well-managed milk plants gave evidence that about 0.1 percent of the milk received was lost through incomplete emptying of milk cans, while the total losses averaged 0.5 percent. The possibility of utilizing recovered milk for manufacturing purposes and the relation of uncovered milk to the sewage disposal problem are presented.

Manual for milk and cream testers in Maryland, C. W. ENGLAND (*Maryland Sta. Bul.* 423 (1938), pp. 121-160, figs. 12).—This is a revision of parts 1 and 3 and supersedes Bulletin 401 (E. S. R., 77, p. 242).

The calculation of fat corrected milk by means of a nomograph chart, F. B. HEADLEY. (Nev. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 1, pp. 41, 42, fig. 1).—A nomograph chart, based on the conversion factors of Perkins (E. S. R., 77, p. 534), is presented by which it is possible to determine quickly the 4-percent fat-corrected weight equivalent of lots of milk of any given fat content without mathematical computation.

The status of pasteurization of milk and milk products, M. J. MACK ET AL. (*Milk Plant Mo.*, 28 (1939), No. 2, pp. 29-32).—In this report of the milk and dairy products committee of the American Public Health Association, a résumé of the present status of pasteurization deals particularly with the food value of raw v. pasteurized milk, the effect of pasteurization on certain dietary essentials, the pasteurization of milk products, changing trends in pasteurization equipment and methods, and tests for efficiency of pasteurization. Forty-six references are cited.

Prevention of destruction of vitamin C during pasteurization by carbon dioxide, A. D. PRATT. (Va. Expt. Sta.). (*Va. Acad. Sci. Proc.*, 1938, p. 64).—Milk pasteurized in an atmosphere of carbon dioxide was not only a more potent source of vitamin C than milk pasteurized in the presence of air but was also more potent than the raw milk, suggesting that the reversibly oxidized ascorbic acid is converted by the reducing action of carbon dioxide to physiologically active L-ascorbic acid.

Effects of high voltage on the bacterial content of milk, I. J. SANDORF (Nev. Engin. Expt. Sta. Bul. 3 (1938), pp. 14, figs. 9).—A study of the effect on the bacterial content of milk of applying successive "shots" of high-voltage electricity indicated that the use of high electric gradients of the order of 25,000 v. per centimeter resulted in considerable reduction in average bacterial count.

Irradiation of milk: Factors affecting antirachitic response, H. H. BECK, H. C. JACKSON, and K. G. WECKEL. (Wis. Expt. Sta.). (*Indus. and Engin. Chem.*, 30 (1938), No. 6, pp. 632-639, figs. 10).—The apparatus used in this investigation was arranged so that film area and capacity, radiation intensity, and distance of the radiation source from the film might be controlled and varied. Radiation was provided by a Hanovia quartz mercury-vapor arc. In trials with fresh milk, maximum vitamin D synthesis occurred when the arc was 6 in. distant from the center of a flowing film. All effective radiation was utilized by a film whose width was no more and length no less than twice the perpendicular distance to the arc. The vitamin D potency of irradiated milk had a parabolic relation to the amount of active radiation applied, whereas a hyperbolic relation was found to exist between vitamin D content and film capacity. Variations in vitamin D potency of the milk irradiated in a thin vertical film were only from 50 to 60 percent as great as the responsible combined variations in intensity and film capacity when the variations were expressed as percentage deviations from a mean. The evidence indicated that the data obtained with fresh milk are equally applicable to evaporated milk.

Sanitary problems in connection with the use of the homogenizer, W. J. CORBETT. (Univ. Ill.). (*Milk Dealer*, 28 (1939), No. 4, pp. 42, 44, 46).—A comparison of the bacterial counts of regular and homogenized milks at different seasons of the year showed a consistently higher count in the homogenized samples. Increases in counts due to homogenization were somewhat greater at the beginning than in the middle or at the end of the run. Homogenization of sterile milks indicated some "pick up" of organisms from the homogenizer, but not nearly as much as the increase in count when high-count milk was homogenized. The increase in count was much greater when these types of organisms existing in clumps were present than in the case of those existing singly or in pairs. These increases occurred regardless of whether homogenization took place before or after pasteurization. Normally, bacterial growth occurred much more rapidly in homogenized than in normal milk. However, when each type of milk was sterilized and reinoculated with pure cultures the growth rate was similar in each, suggesting that during homogenization some rapid growing organisms are picked up which multiply very rapidly when milk is stored at temperatures above 50° F.

Determination of carotene and vitamin A in milk, F. R. OLSON, D. M. HEGSTED, and W. H. PETERSON. (Wis. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 2, pp. 63-66).—Results obtained by an extraction method for determining the carotene and vitamin A in whole milk which is fully described were in close agreement with those secured when butterfat was used as the starting material. Comparative assays of fresh, stored, and frozen milks indicated that milk can be stored at low temperature or frozen for considerable periods without affecting its carotene or vitamin A content.

Vitamin A activity of milk fat, L. A. MOORE (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 3, pp. 169-174).—Monthly milk samples from (1) mixed creamery milk, (2) a Holstein cow receiving pasture in season, and (3) a Holstein cow continuously confined to a ration of alfalfa hay and grain were assayed for vitamin A activity. The samples from sources 1 and 2 showed marked seasonal variation, having the least vitamin A activity in the late spring before pasture was available, increasing very rapidly after the animals were turned on pasture, and reaching greatest potency in the late summer months. The addition of A. I. V. alfalfa silage or A. I. V. oat and pea silage to winter rations more than doubled the vitamin A activity of the milk produced. On the average, 1 qt. of milk per day had sufficient vitamin A activity to meet the minimum vitamin A requirements of an adult person.

The quantitative determination of vitamin C in milk, C. A. KNIGHT, R. A. DUTCHER, and N. B. GUERRANT. (Pa. State Col.). (*Science*, 89 (1939), No. 2304, pp. 183-185, fig. 1).—A method and apparatus for collecting milk samples directly from the cow's udder in a carbon dioxide atmosphere without exposure to light or air are described, also a method of preparing a stable titrating solution of 2,6-dichlorobenzeneindophenol. Titration of untreated milk samples collected by this method and of samples treated with hydrogen sulfide gave ascorbic values in close agreement, indicating that the ascorbic acid in milk collected in this manner was in the reduced form. No adsorption of ascorbic acid by the milk proteins could be demonstrated.

Ascorbic acid content of milk of various species as influenced by ascorbic acid injection and diet, R. RASMUSSEN, R. BOGART, and L. A. MAYNARD. (Cornell Univ.). (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 3, pp. 502-505, fig. 1).—The ascorbic acid content of the milk of the ewe, cow, mare, and guinea pig was studied. The ascorbic acid values for ewes' milk, determined at intervals during the lactation period, ranged from 25 to 40 mg. per quart.

With both ewes and cows, intravenous injections of ascorbic acid resulted in a temporary sharp rise in the vitamin C content of the milk. Samples of mares' milk ranged from 27 to 115 mg. of ascorbic acid per quart, with evidence that feed was a factor in the wide variations noted. Milk from guinea pigs receiving a ration of oats and hay with a limited amount of green grass contained about 110 mg. per quart as compared with nearly 400 mg. per quart for guinea pigs receiving green grass ad libitum and 711 mg. per quart for one receiving green grass plus 40 mg. of ascorbic acid daily, thus indicating the marked effect of feed on the ascorbic acid content of the milk from this species.

A study of breed and seasonal variations in the ascorbic acid content of certified milk from Guernseys and Holsteins, A. D. HOLMES, F. TRIPP, E. A. WOELFFER, and G. H. SATTERFIELD. (Univ. N. C. et al.). (*Jour. Nutr.*, 17 (1939), No. 2, pp. 187-198, fig. 1).—Samples of raw certified milk collected from Guernsey and Holstein herds at bimonthly intervals for 1 yr. were assayed for ascorbic acid content by the direct titration method. Guernsey samples ranged from 17.76 to 23.37 mg. per liter (average 20.54) and Holstein samples from 15.72 to 20.44 mg. (average 18.17). Considerable seasonal variation was noted for both breeds, the greatest concentration occurring in February while the second slightly lower peak occurred in late fall. No effect of ration or period of lactation on the ascorbic acid content of the milk could be established.

Relation of vitamin C, lecithin, and carotene of milk to the development of oxidized flavor, G. H. BECK, C. H. WHITNAH, and W. H. MARTIN. (Kans. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 1, pp. 17-29, figs. 2).—Individual samples of milk collected at monthly intervals from cows of the Jersey, Guernsey, Holstein, and Ayrshire breeds were scored for flavor and analyzed for vitamin C, lecithin, and color intensity of the milk fat. Oxidized flavor occurred in 11 percent of all samples studied. The development of oxidized flavor bore no apparent relationship to the vitamin C content of the fresh sample, to the amount of vitamin C lost during 3 days' storage, or to the lecithin content of the milk. There appeared to be a relation between the color intensity of milk fat as produced by the different breeds and the development of oxidized flavor. This color defect was detected in 6.1, 7.8, 15.8, and 19.4 percent of the Jersey, Guernsey, Holstein, and Ayrshire samples, respectively. Moreover, the average color intensity of oxidized samples in each breed group averaged consistently lower than that of nonoxidized samples from this same breed. Feeding relatively small amounts of carotene to cows which had consistently produced milk with oxidized flavor overcame this defect.

Oxidized flavor in milk.—VI, A study of the relation of titratable acidity to metal-developed oxidized flavor in milk, W. C. BROWN and R. B. DUSTMAN. (W. Va. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 1, pp. 31-35, fig. 1).—Continuing this series (E. S. R., 78, p. 243), a study was made of 220 individual cows' samples of milk, in which oxidized flavor was induced by the addition of 1.3 p. p. m. of copper after pasteurization. No relationship was found to exist between the acidity of the freshly drawn samples and the intensity of oxidized flavor development, both normal and oxidized flavored milk occurring in the low acid and high acid milks in approximately the same proportion. Standardization of the acidity of fresh mixed herd milk to 0.13 percent had no effect in preventing the development of oxidized flavor when copper was added after pasteurization. Possible reasons for the variation in these findings and those reported by the [Connecticut] Storrs Experiment Station (E. S. R., 78, p. 390) are discussed.

Distribution of flavors in milk at the receiving platform, G. M. TROUT (Michigan Sta. Quart. Bul., 21 (1938), No. 3, pp. 228-250).—Flavor studies made

on 920 cans of milk in late summer, representing a large number of producers, showed 44.9 percent of the samples to possess a clean, pleasant flavor. Of the various types of off-flavors found in the remaining samples, feed flavors were most common, making up 43.2 percent of the total, while musty flavors were encountered in 19.9, high acidity in 14.4, and unclean in 11.4 percent, with barny, cowy, oily, or miscellaneous off-flavors making up the balance. Suggestions are offered for overcoming the various types of off-flavors encountered.

Preserving cream with salt (*Natl. Butter and Cheese Jour.*, 30 (1939), No. 3, pp. 26, 28).—A method of preserving cream by the addition of salt, for which a public service patent has been granted O. E. Williams of the U. S. Department of Agriculture, is fully described.

The phosphatase test: Its application to sour cream and sour cream butter, E. H. PARFITT and W. H. BROWN. (Purdue Univ.). (*Natl. Butter and Cheese Jour.*, 30 (1939), No. 1, pp. 12-14).—The authors briefly summarize the available information on the application of the phosphatase test to sour cream and sour cream butter, and present original data to indicate that this test is a good tool to use in controlling the pasteurization of cream for butter making and in detecting butter made from inadequately pasteurized cream but that in the present state of development it should not be considered as a control instrument.

Production of diacetyl from citric acid in butter cultures, E. A. PRILL and B. W. HAMMER. (Iowa Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 2, pp. 67-77, figs. 8).—A study of the changes occurring in the diacetyl and acetylmethylcarbinol contents of butter cultures under varying conditions gave evidence that the addition of a small amount of citric acid (about 0.15 percent) to the starter milk, agitation and aeration of the culture, decreasing the pH of the ripened culture by the addition of small amounts of citric acid or even sulfuric acid, and holding the ripened culture at a practical temperature for from 9 to 15 hr., all favored a high diacetyl content in the starter. In general, the same conditions favored a high acetylmethylcarbinol content, although the increase of this component at low temperature was slower than for diacetyl.

Changes in the diacetyl and the acetylmethylcarbinol contents during the manufacture of butter, E. A. PRILL and B. W. HAMMER. (Iowa Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 2, pp. 79-88).—The diacetyl and acetylmethylcarbinol contents were determined in creams at various stages of processing and in the butter during various stages of manufacturing. Marked but inconsistent changes in the diacetyl content occurred during the neutralization and pasteurization of sour cream, while changes in the acetylmethylcarbinol content were relatively small. Progressive increases in diacetyl occurred after additions of either regular butter culture, aerated culture, or modified aerated culture to pasteurized cream (either sweet or sour), after holding the mixtures at low temperature overnight, and after partial churning of the mixtures. The content of the acetylmethylcarbinol increased somewhat during the holding period. There was no close relationship between the diacetyl content of the butter culture added to the cream and that of the resulting butter. High diacetyl cultures gave butter of higher diacetyl content than did regular cultures, although not in proportion to the contents in the respective cultures. On the average 8.8 percent of the diacetyl and 4.5 percent of the acetylmethylcarbinol plus diacetyl in the churning mixture were retained in the butter.

Pasteurization of milk for cheesemaking, W. V. PRICE. (Univ. Wis.). (*Natl. Butter and Cheese Jour.*, 29 (1938), Nos. 21, pp. 16, 17, 33-37; 22, pp. 20, 21).—Practical reasons for the widespread adoption of pasteurization of milk for cheesemaking are summarized, with 57 references to the literature.

Milk and starters for brick cheese, W. LANGHUS, P. R. ELLIKER, and W. V. PRICE. (Univ. Wis.). (*Jour. Dairy Sci.*, 22 (1939), No. 2, pp. 101-106.)—In a study at 12 Wisconsin factories the cheese milk graded poor in the majority of cases and seldom better than fair, indicating that more careful selection of the milk would result in better cheese. The starters varied greatly in quality and predominating type of organism. It appeared that the cheese was usually no better than the quality of starter used in its manufacture and that improved methods of propagating starters in cheese factories were needed.

Identification of Roquefort cheese, I. D. GARARD, A. MINSKY, J. H. BAKER, and V. PASCALE. (Rutgers Univ. et al.). (*Indus. and Engin. Chem.*, 29 (1937), No. 10, pp. 1167-1171, figs. 2).—Numerous authentic samples of ewe's milk Roquefort cheese and cow's milk blue cheese were analyzed in the course of this study. Polenske values for fat extracted from the Roquefort cheeses varied from 3.6 to 5.95, whereas values from the cow's milk cheeses did not exceed 2.9 and were usually below 1.8, leading to the conclusion that a Polenske value of less than 3 for blue-mold cheese is conclusive evidence that the cheese is not Roquefort. Fat melted from Roquefort cheese was invariably white or pale yellow with a green tinge, while fat from cow's milk cheese was always yellow in color.

The relation of the quality of milk to the grade of Swiss cheese, L. A. ROGERS, R. E. HARDELL, and F. FEUTZ. (U. S. D. A., Ohio State Univ., and Univ. Wis.). (*Jour. Dairy Sci.*, 22 (1939), No. 1, pp. 43-48, figs. 2).—Data collected on more than 500 cheeses in 20 factories in Ohio and Wisconsin indicated a close relationship between the quality of cheese milk as measured by the methylene blue reduction test and the quality of the resulting Swiss cheese. When the methylene blue reduction time was under 3 hr. there was only about one chance in three of the cheese grading A or B, while if the reduction time was over 3 hr. two out of three cheeses could be expected to be of A or B grade. When the culturing and manufacturing processes were so adjusted as to give a pH between 6.35 and 6.51 at dipping time, a high percentage of cheeses could be expected to grade A or B, while a pH of over 6.51 greatly reduced the chance of producing high-grading cheese. When the pH at dipping fell below 6.3, it was generally attributable to active thermophilic coccus organisms which developed even during cooking time, and the defective cheese could be attributed directly to the abnormally high acidity.

Effects of the cold storage temperature, heat treatment, and homogenization pressure on the properties of frozen condensed milk, R. W. BELL. (U. S. D. A.). (*Jour. Dairy Sci.*, 22 (1939), No. 2, pp. 89-100).—Homogenization pressures ranging from 1,000 to 4,000 lb., pasteurization temperatures ranging from 61° C. for 30 min. to 82° for 15 min., and storage temperatures of from 0° to -17° were employed in these studies. Heating the milk to a temperature sufficiently high to destroy the enzyme hazards prior to other processing steps was essential to prevent the development of rancid flavor. In order to retard oxidized flavor development the milk should be exposed to as severe a heat treatment as possible without impairing its body and flavor. A temperature of 76.5° for 8 min. proved most satisfactory in these trials. Homogenization proved desirable in preventing the formation of an undesirable layer of fat on the surface of the frozen condensed milk and also aided in retarding oxidized flavor development. Pressures of from 2,000 to 3,000 lb. proved most desirable. The unsterilized condensed samples kept better in frozen storage than at 0°, and other conditions being equal the samples stored at -17° were more susceptible to oxidized flavor development than those at -7°. It was shown that under

favorable circumstances market milk could be satisfactorily preserved as homogenized frozen condensed milk for a considerable period.

Preserving the freshness of ice cream through the use of antioxidants, A. D. BURKE and R. M. NEWMAN. (Ala. Polytech. Inst.). (*Ice Cream Rev.*, 22 (1939), No. 7, pp. 50, 86-88, 90, 92).—This report essentially confirms previous findings by the Pennsylvania, Massachusetts, and Illinois Experiment Stations (E. S. R., 78, pp. 245, 693; 79, p. 102) on the retardation of oxidized flavor development in ice cream by adding 0.5 percent of oat flour to the ice cream mix. When the normal percentage of gelatin in the mix was slightly reduced this level of oat flour did not impair the body and texture of the ice cream but did impart a slight oat flour flavor.

Protection of ice cream against contamination after pasteurization, F. E. NELSON. (Kans. Expt. Sta.). (*Ice Cream Rev.* 22 (1939), No. 7, pp. 46, 69, 70).—The studies reported indicate that the phosphatase test may be effectively used for detecting the efficiency of pasteurization of ice cream mixes, and that samples negative to the test and showing the presence of the *Escherichia-Aerobacter* group of organisms are indicative of contamination after pasteurization. Various sources of contamination are discussed, and suggestions offered for the care of the ice cream manufacturing and packaging equipment.

VETERINARY MEDICINE

[Report of work in animal parasitology and pathology] (*California Sta. [Blen.] Rpt.* 1937-38, pp. 67-77).—The work of the biennium 1937-38 with diseases and parasites of livestock referred to (E. S. R., 76, p. 848) includes pullorum disease, swell head, and *Hexamita* infection in turkeys, paratyphoid infection of chicks and poults, vaccination for fowl pox, infectious coryza of chickens and other causes of poultry mortality, bovine trichomoniasis, bovine tuberculosis, Bang's disease, mastitis in cows, studies on bovine anaplasmosis, the development of a new and effective hog cholera vaccine, caseous lymphadenitis and enterotoxemia of sheep, stomach worm (*Ostertagia circumcincta*) of sheep, flies (*Lucilia sericata* and *Phormia regina*) that produce myiasis in livestock, and roundworm (*Trichostrongylus axei*) of cattle and sheep.

[Work in animal pathology by the Florida Station] (*Florida Sta. Rpt.* 1938, pp. 61, 65, 66, 67, 68).—The work of the year (E. S. R., 79, p. 534) again relates to investigations by D. A. Sanders of hemorrhagic septicemia in cattle and swine (E. S. R., 80, p. 251) and of enzootic broncho-pneumonia in calves; the etiology of fowl paralysis, leukemia, and allied conditions in animals, by M. W. Emmel (E. S. R., 80, p. 400); and a study of plants poisonous to livestock in Florida, by Sanders, Emmel, and E. West, including *Ambrosia ambrosioides* and *Lupinus angustifolius*.

[Work with livestock diseases and parasites by the South Dakota Station] (*South Dakota Sta. Rpt.* 1938, pp. 22-26, 37-39, 50).—The work of the year (E. S. R., 79, p. 535) reported upon includes alkali disease (selenium poisoning), forms of selenium in the soil, sulfur-selenium studies, selenium content of various plants at different stages of growth, selenium as a stimulant to plant growth, distribution of selenium in germinated seeds, toxicity of several forms of organic selenium, and the relationship of arsenic to selenium poisoning, all by O. E. Olson; a study of the properties of the oil of chenopodium obtained by cross-fertilization of *Chenopodium ambrosioides* with a wild variety, as well as the study of the anthelmintic value of the oil obtained from this

cross in the treatment of ascarids, by F. J. LeBlanc and T. R. Wright; and hemorrhagic septicemia, by J. B. Taylor.

[Work in animal pathology by the Washington Station], E. C. McCULLOCH (*Washington Sta. Bul.* 368 (1938), pp. 70-72).—The work of the year reported upon (E. S. R., 79, p. 391) relates to the development and spread of bovine mastitis, the efficiency of farm disinfectants, lamb dysentery, and hard liver disease of swine.

Report of the veterinary division, 1937, H. V. M. METIVIER (*Trinidad and Tobago Dept. Agr. Rpt.*, 1937, pp. 60-65).—The work of the year, particularly on disease control and briefly on research operations, is reported.

[Contributions on animal pathology and parasitology] (*Onderstepoort Jour. Vet. Sci. and Anim. Indus.*, 10 (1938), No. 2, pp. 243-277, 365-441, figs. 33).—Among the contributions presented are: Variation in the Colony Form of the Anthrax Bacillus, by M. Sterne (pp. 245-250); South African Helminths—II, Some Taenias From Large Wild Carnivores, by R. J. Ortlepp (pp. 253-277) (E. S. R., 80, p. 539); Some Physiological Aspects of the Genus *Tribulus*, by M. Henrici (pp. 367-392); On the Constitution of the Bitter Principle "Geigerin"—I, The Isolation of Various Degradation Acids, by H. L. De Waal (pp. 395-410); The Detection of Strychnine in Carcasses and Corpses, by D. G. Steyn (pp. 411-418); Quantitative Studies Upon Porphyrin Excretion in Bovine Congenital Porphyrinuria (Pink Tooth), I, by C. Rimington, G. C. S. Roets, and P. J. J. Fourie (pp. 421-429); A Further Case of Congenital Porphyrinuria (Pink Tooth) in a Living Grade Friesland Cow in South Africa (Cedara Case), by P. J. J. Fourie and C. R. Rimington (pp. 431-436); and A Rapid Phase Test for Distinguishing Between Carotinoid and Bile Staining of Fat in Carcasses, by C. Rimington and P. J. J. Fourie (pp. 439-441).

A textbook of medical bacteriology, D. L. BELDING and A. T. MARSTON (*New York and London: D. Appleton-Century Co.*, [1938], pp. XXXVIII+592, pl. 1, figs. 43).—This concise, yet comprehensive, work, prepared in collaboration with S. B. Hooker, S. C. Dalrymple, J. P. Bill, and M. A. Derow, is presented in several sections, as follows: 1, general bacteriology (pp. 1-124); 2, medical bacteriology (pp. 125-199); 3, pathogenic eubacteriales (pp. 201-289); 4, the pathogenic actinomycetales (higher bacteria) (pp. 291-327); 5, the pathogenic fungi (pp. 329-371); 6, the spirochaetes (pp. 373-397); 7, the viruses, rickettsiae, and bacteriophages, by S. C. Dalrymple (pp. 399-437); 8, immunity, by M. A. Derow and S. B. Hooker (pp. 439-486); and 9, sanitary and economic bacteriology (pp. 487-549). Special methods of staining are dealt with in an appendix (pp. 551-566).

[Contributions on bacteriology and therapeutics] (*Jour. Bact.*, 36 (1938), No. 6, pp. 665, 666, 668, 669, 670).—Abstracts from contributions presented are: Some Cultural Characteristics of the Genus *Corynebacterium*, by R. F. Brooks (p. 665) and Cultural Characters of Certain Food-Poisoning Micrococci, by W. C. Haynes (p. 666) (both N. Y. State Expt. Sta.); Allergic Skin Tests for *Brucella* Infection, by D. R. Cordy (p. 668) and *Brucella* Agglutinins in Horses, by W. S. Stone (pp. 668, 669) (both Cornell Univ.); The Bacteriostatic Action of Sulfanilamide Upon Hemolytic Streptococci of Human Origin, by E. Neter (p. 669); and The Effect of Thyroid Activity on the Production of Agglutinins for *Streptococcus pyogenes*, by L. Marshak (pp. 669, 670).

Poisonous plants of the United States, W. C. MUENSCHER (*New York: MacMillan Co.*, 1939, pp. XVII+266, figs. 75).—A manual in which information on the principal plants is brought together in concise form. Part 1 (pp. 1-18) is devoted to the nature and classification of poisonous plants and to plants poisonous or injurious under special conditions. Part 2 (pp. 19-239) presents

concise accounts of specific plants, the arrangement being by families. An 11-page list of references to the literature cited is included.

The alkaloids of *Senecio* species.—I, The necines and necic acids from *S. retrorsus* and *S. jacobaea*. II, Some miscellaneous observations. III, *Senecio integerrimus*, *S. longilobus*, *S. spartioides*, and *S. riddellii*. IV, *Erechtites hieracifolia* (L.) Raf., R. H. F. MANSKE (*Canad. Jour. Res.*, 5 (1931), No. 6, pp. 651-659; 14 (1936), No. 1, Sect. B, pp. 6-11; 17 (1939), No. 1, Sect. B, pp. 1-9).—Studies of species of *Senecio* here reported are of importance because the alkaloids found present appear to be rather toxic and produce cumulative effects when ingested by livestock in small doses over extended periods.

Snake bites among domestic animals, R. L. DITMARS (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 383-388, figs. 5).—Recommendations are made for the treatment of domestic animals, particularly dogs, which are frequently bitten by poisonous snakes. These include "(1) suction by simple, inexpensive, and specifically designed apparatus which is readily available, and (2) neutralization of poison by veterinary antivenin. The administration of antivenin may be intramuscular, or intravenous (the latter in case of rapidly progressive or advanced symptoms) and the amounts of injection should be contingent to the size of the animal (larger amounts for smaller animals) and to the size of the snake and amount of poison injected. The latter point is indicated by the gravity of the symptoms. The combination of both treatments is advisable."

Anaphylaxis as related to biologic prophylaxis and treatment of animals, J. REICHEL (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 418-420).

The mode of action of drugs of the sulphonamide group, J. MCINTOSH and L. E. H. WHITBY (*Lancet* [London], 1939, I, No. 8, pp. 431-435).—The authors find that these drugs do not stimulate leucocytic or phagocytic activity; do not affect the speed of production or the quantity and quality of specific immune bodies; both in vivo and in vitro are not instantly active, and there is a quantitative relationship between the effective dose of the drug and the bacteria affected; are active on highly virulent organisms and those in the logarithmic phase of multiplication; are inactive on rough organisms; and are not germicides. It is considered probable that they act by neutralization of some metabolic function or enzymatic activity.

Sulfanilamide therapy of bacterial infections, R. R. MELLON, P. GROSS, and F. B. COOPER (*Springfield, Ill.: Chas. C. Thomas*, 1938, pp. XIII+398, figs. 16).—This work, presented in four sections and an addenda, relates to the therapy of diseases caused by hemolytic streptococci, pneumococci, meningococci, and gonococci. A bibliography of 305 titles is included.

Some diseases of the eyes of lower animals: Methods of examination, diagnosis, and treatment, C. F. SCHLOTTHAUER (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 404-408).

Skin diseases occurring in both man and animals, H. FOX (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 398-403).

An annotated check list of the parasites of animals in Puerto Rico, H. L. VAN VOLKENBERG (*Puerto Rico Sta. Circo*, 22 (1939), pp. 12).—The parasites of domestic animals in Puerto Rico with their hosts are listed systematically under the headings Arthropoda, Protozoa, Platyhelminthes, Nematelminthes, and exotic species. A bibliography of these parasites in Puerto Rico containing 49 titles is included.

Ixodes marmotae: A new species of tick from marmots (Acarina: Ixodidae), R. A. COOLEY and G. M. KOHLIS (*Pub. Health Rpts. [U. S.]*, 53 (1938), No. 49, pp. 2174-2181, figs. 20).—A description is given of a new species

of tick that is of common occurrence on marmots in northwestern United States under the name of *I. marmotae*. It has been collected in Idaho, Montana, Oregon, Wyoming, and Washington. It is not known to attack man.

The tick problem, J. MACLEOD (*Vet. Rec.*, 50 (1938), No. 39, pp. 1245-1249, 1250, figs. 3).—A discussion of the control of the British sheep tick *Ixodes ricinus* L.

Longevity of the tick *Ornithodoros turicata* and of *Spirochaeta recurrentis* within this tick, E. FRANCIS (*Pub. Health Rpts.* [U. S.], 53 (1938), No. 51, pp. 2220-2241, pls. 3, figs. 6).—The author reports having found that the tick *O. turicata* collected in dry caves in Texas and naturally infected with virulent *S. recurrentis* after 5 yr. of starvation transmitted it to a monkey on which it fed. Ticks which infected a monkey after 4 yr. of starvation infected a second monkey by feeding 2.5 yr. later, thus demonstrating 6.5 yr. of natural infection in ticks.

"Of 119 *O. turicata* ticks collected in caves in Texas in 1931, 14 are still living at the end of 7 yr., all of which are females. Hereditary transmission of relapsing fever spirochetes was obtained through the eggs from naturally infected ticks and from ticks artificially infected to larvae and first nymphs of the next generation, which by feeding infected mouse, monkey, and man. Transmission was successful when white mice ate bedbugs infected with *S. recurrentis* but failed when mice were bitten by infected bedbugs (*Cimex lectularius*). Spirochetes could not be demonstrated in monkey lice during the first 16 days of subsistence on spirochete-positive relapsing fever monkey blood but were demonstrated daily after the seventeenth day. These infected lice failed to infect a monkey on which 1,550 of them were liberated. Immunity to relapsing fever could not be demonstrated in mouse or monkey 9 mo. to a year after their original infection. Neoarsphenamine failed to show specific therapeutic value in three human cases infected with the Texas strain of relapsing fever."

A list is given of 20 references to the literature.

A filter-passing infectious agent isolated from ticks, I-IV (*Pub. Health Rpts.* [U. S.], 53 (1938), No. 52, pp. 2259-2282, fig. 1).—In the first of the four contributions on a filter passer here presented G. E. Davis and H. R. Cox report upon its isolation from *Derma-centor andersoni*, reactions in animals, and filtration experiments (pp. 2259-2267); in the second R. R. Parker and G. E. Davis report on its transmission by *D. andersoni* (pp. 2267-2270); in the third H. R. Cox gives a description of the organism and cultivation experiments (pp. 2270-2276); and in the fourth R. E. Dyer deals with human infection by it (pp. 2277-2281).

Acquired immunity to ticks, W. TRAGER (*Jour. Parasitol.*, 25 (1939), No. 1, pp. 57-81, figs. 8).—It has been found that a single infestation of guinea pigs or rabbits with larvae of the American dog tick induces an acquired immunity which effectively prevents subsequent batches of larvae from engorging. "In guinea pigs, the immunity develops fully within 2 weeks after the start of the first infestation and lasts at least 3 mo. Guinea pigs first infested with either *D[erma-centor] variabilis* or *D. andersoni* show a cross immunity to larvae of the other species. Similarly, rabbits first infested with either *D. variabilis* or *Haemaphysalis leporis-palustris* show cross immunity to larvae of the other species. Deer mice become relatively resistant to larvae of *D. variabilis* after two or three infestations. The repeated infestation of guinea pigs with nymphs or adults of *D. variabilis* results in a marked reduction in the amount of blood taken by ticks of the later batches. The immunity of guinea pigs to larvae of *D. variabilis* can be produced artificially by the intracutaneous inoculation of an extract of larval ticks. It can be passively transferred by the

intraperitoneal inoculation of serum from guinea pigs hyperimmunized by repeated infestations with nymphs."

A list is given of 35 references to the literature.

A study of hemolytic streptococci with reference to the correlation between their group specific substances and biochemical characteristics. M. C. HEOHLER and M. A. FARRELL (Pa. State Col.). (*Jour. Infect. Diseases*, 63 (1938), No. 3, pp. 225-231).—A study made of the serological and biochemical properties of 42 strains of hemolytic streptococci is reported upon. By means of the precipitin test 37 of the 42 strains were classified into the 7 serological groups of Lancefield. "Five of the 7 serological groups, in a large majority of cases, show a definite relation to the source of the strains. The biochemical and cultural characteristics of all strains within a group are somewhat variable although predominant group reactions are noted. Certain correlations are indicated between the group specific substances and fermentative reactions."

Combined serum and sulphanilamide in the treatment of streptococcal infections in mice, H. LOEWENTHAL (*Lancet* [London], 1939, I, No. 4, pp. 197-199).—The author reports having found that a single dose of sulfanilamide administered at the time of infection with hemolytic streptococci will protect only a minority of normal mice. When administered to mice which have received from 16 to 18 hr. before infection a dose of antiserum incapable by itself of preventing death it protects the majority of them. Mice infected with hemolytic streptococci can be effectively treated with a combination of sulfanilamide and antiserum even if this treatment is begun as long as 18 hr. after infection, when the animals are already severely ill. Since neither sulfanilamide nor antiserum alone can achieve this result it appears that these two therapeutic agents act in a different but complementary manner.

Use of yolk sac of developing chick embryo as medium for growing rickettsiae of Rocky Mountain spotted fever and typhus groups, H. R. COX (*Pub. Health Rpts.* [U. S.], 53 (1938), No. 51, pp. 2241-2247).—Description is given of a technic whereby the yolk sac of the developing chick embryo is used for the cultivation of rickettsiae. By this method the rickettsiae of Rocky Mountain spotted fever, endemic typhus, European (epidemic) typhus, boutonneuse fever, Brazilian spotted fever, and an unidentified rickettsial disease recently isolated from *Amblyomma maculatum* (ticks) have been readily maintained in serial passage. The yolk sac suspensions of spotted fever and endemic typhus have been as a rule 100 to 1,000 times more infective than mammalian tissues or other tissues of the developing chick and approach the limits reported for tick tissues. In addition, in all the diseases studied, with the possible exception of the *A. maculatum* infection, yolk sac suspensions have produced a more severe infection with a shortened incubation period. Rickettsiae of all the diseases studied, with the exception of European typhus, were readily and consistently found in the yolk sacs.

Further studies on biochemical and serological varieties of *Salmonella typhi-murium*, P. R. EDWARDS and D. W. BRUNER (Ky. Expt. Sta.). (*Amer. Jour. Hyg.*, 29 (1939), No. 1, Sect. B, pp. 24-31).—The authors have found that the behavior of cultures of *S. typhimurium* in the biochemical tests described can be utilized to distinguish epidemiologically related strains. All cultures from a single outbreak of disease are alike in possessing or lacking antigen I of the Kauffmann-White classification. All the cultures included in this study were isolated from pigeons lacking antigen V of the Kauffmann-White schema. It is suggested that the "ammonia weak" strains of Hohn and Hermann constitute a single biochemical type of the IV variant found in pigeons.

A list is given of 22 references to the literature.

Observations on the bionomics of strongyloid larvae in pastures.—I, The duration of infection in pasture herbage, E. L. TAYLOR (*Vet. Rec.*, 50 (1938), No. 40, pp. 1265-1272, figs. 9).—Observations on the longevity of strongyloid larvae in grass grown in boxes and kept in the open field are considered. They suggest that considerable benefit may result from resting a pasture even for a few weeks, during which time a considerable reduction in the number of larvae may have occurred.

Specificity of artificial acquired immunity to *Strongyloides ratti*, A. J. SHELDON (*Amer. Jour. Hyg.*, 29 (1939), No. 2, Sect. D, pp. 47-50).—The previous report (E. S. R., 77, p. 851) of artificial immunization of rats against infection with *S. ratti* as a result of serial injections of heat-killed larvae is confirmed. "The specificity of this immunity is established, in that it was not possible to immunize rats against infection with *S. ratti* by means of serial injections of heat-killed larvae of *S. stercoralis*. Although these two forms are closely related and are morphologically and biologically very similar, they appear to be, nevertheless, immunologically different."

Studies on age resistance against trypanosome infections, I-III (*Amer. Jour. Hyg.*, 29 (1939), No. 1, Sect. C, pp. 13-43, fig. 1) —Part 1 of this contribution, by M. H. Kolodny, deals with the resistance of rats of different ages to infection with *Trypanosoma cruzi*, with a list of 83 references to the literature (pp. 13-24); part 2, by C. J. Duca, with the resistance of rats of different age groups to *T. lewisi* and the blood response of rats infected with this parasite, with a list of 12 references (pp. 25-32); and part 3, by J. T. Culbertson and W. R. Kessler, with vaccination of rats against *T. lewisi* with special reference to the response of different age groups, with a list of 15 references (pp. 33-43).

Studies of age resistance against trypanosome infections.—IV, The activity of Germanin (Bayer 205) upon *Trypanosoma equiperdum* infections in rats of different age groups, J. T. CULBERTSON (*Amer. Jour. Hyg.*, 29 (1939), No. 2, Sect. C, pp. 73-77).—In continuation of the above studies the author reports having observed a difference in the time required for disappearance of *T. equiperdum* from the blood of infected rats of different age groups after treatment with Germanin.

The serum potassium level in *Trypanosoma equiperdum* infection in rats: The role of potassium in death from this infection, R. L. ZWEMER and J. T. CULBERTSON (*Amer. Jour. Hyg.*, 29 (1939), No. 1, Sect. C, pp. 7-12, fig. 1).—The authors report that the serum potassium level of rats dying of *T. equiperdum* infection is markedly increased, this increase being initiated about 24 hr. before death. It is suggested that this elevated serum potassium is a significant factor in the cause of death of the infected animals.

The effect of splenectomy and blockade on the protective titer of antiserum against *Trypanosoma equiperdum*, L. R. KUHN (*Jour. Infect. Diseases*, 63 (1938), No. 2, pp. 217-224, fig. 1).—The author has found that the protective titer of sheep anti *T. equiperdum* serum, when injected intraperitoneally in mice, is appreciably reduced provided the mice are splenectomized and blockaded with India ink or normal serum and injected subcutaneously with from 2,500 to 3,000 trypanosomes, but is not reduced if the mice are only splenectomized or if the mice are splenectomized and blockaded with specific (i. e., sheep anti *T. equiperdum*) serum. Furthermore, it is only slightly reduced in mice splenectomized and blockaded with India ink and injected subcutaneously with from 1,200 to 1,600 trypanosomes. Splenectomy plus blockade appears to have no effect upon the resistance of mice to trypanosomes specifically sensitized in vitro. The effect of splenectomy and blockade upon

the protective titer of trypanocidal serum cannot, therefore, be due to inhibited phagocytosis, decreased complement, or reduced opsonin, but it may be due to interference with the concentration of passively acquired antibodies in macrophage tissues.

Progress of tuberculosis eradication in Canada, O. HALL (*Canad. Jour. Compar. Med.*, 3 (1939), No. 2, pp. 47-50).

Susceptibility of animals to endemic typhus virus, G. D. BRIGHAM (*Pub. Health Rpts. [U. S.]*, 53 (1938), No. 47, pp. 2078, 2079).—In further work (E. S. R., 78, p. 250) the gray squirrel, fox squirrel, cottontail rabbit, swamp rabbit, chipmunk, and skunk were found to be susceptible to the virus of endemic typhus fever. The gray fox was not susceptible.

Chronic ulcerative cecitis in the rat, B. F. JONES and H. L. STEWART (*Pub. Health Rpts. [U. S.]*, 54 (1939), No. 5, pp. 172-175).—A brief description is given of a spontaneous disease of rats characterized by chronic ulcerative cecitis and chronic lymphangitis, lymphedema, and lymphoid hyperplasia of the lymph nodes of the mesentery.

The diseases of dairy cattle, S. J. EDWARDS (*Jour. Dairy Res. [London]*, 9 (1938), No. 3, pp. 356-377).—This review of progress in the knowledge of mastitis (pp. 356-363), contagious abortion (Bang's disease) (pp. 363-368), and bovine tuberculosis (pp. 368-374), and means for their control, is presented with a list of 137 references to the literature.

Induced cases of traumatic gastritis and pericarditis in dairy cattle, R. W. DOUGHERTY. (Oreg. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 357-362).—In the studies conducted marked changes were noted "in three cows in which foreign bodies were inserted through the wall of the reticulum so that they extended into the peritoneal cavity. The foreign bodies were carried into the reticulum through rumen fistulae. Hemocytological changes occurred in 4 to 6 hr. after the foreign bodies were inserted. Blood changes included an increase in the total white count, an increase in 'stab' cells, the appearance of myelocytes and juveniles in the blood stream, and a relative decrease in lymphocytes. An increase in sedimentation rate was noted in one animal, in which symptoms of pericarditis were induced by forcing the foreign body through the diaphragm until it touched the heart. This animal showed considerable distress. Rumenal contractions decreased as early as 2 hr. after the foreign bodies were inserted. Animals on which the procedure was repeated showed very few visible symptoms. The blood response, however, was quite marked. A comparison between blood pictures and clinical findings on 30 cases indicated that blood examinations are of great value in prognosing as well as diagnosing traumatic gastritis and traumatic pericarditis."

A bacteriologic study of liver abscesses in cattle, I. E. NEWSOM. (Colo. Expt. Sta.). (*Jour. Infect. Diseases*, 63 (1938), No. 3, pp. 232, 233).—Examinations of a series of 100 abscesses from as many different cattle slaughtered at Denver packing houses are reported upon. The findings have led the author to conclude that most liver abscesses observed in slaughter cattle are due to the invasion of *Actinomyces necrophorus*, although occasionally *Corynebacterium pyogenes* and a white coccus may also be present.

Studies on the variation of the blood cells of cattle in health and during Brucella infections, F. N. BELL and M. R. IRWIN. (Wis. Expt. Sta. and U. S. D. A.). (*Jour. Infect. Diseases*, 63 (1938), No. 3, pp. 251-262, figs. 6).—In the experimental work reported, groups of cows which, following an induced infection, "either aborted their fetuses (i. e., susceptible group) or produced living calves at full term (i. e., resistant group), showed the following changes in their peripheral blood cell pictures for the period preceding the infection as con-

trasted with that of the acute stages of the disease: Both resistant and susceptible groups had a significant drop in the average number of leucocytes per cubic millimeter of blood for the period of the counts following the infection. A reduction in mean number was also noted for the red blood cells of each group. Each group of animals, subsequent to infection, showed a definite increase in the average percentage of polymorphonuclear cells. In the resistant group there was a slight, but not significant, rise in the average percentage of monocytes; a very marked increase in the mean proportion of this type of cell was noted in the susceptible animals. Likewise, the reactor individuals possessed a higher percentage of these cells than the normal group, this percentage being practically the same as that of the susceptible individuals during the acute stages of the infection. The average percentage of lymphocytes at all times was in almost direct inverse proportion to that of the polymorphonuclear cells. No significant changes in the average percentages of either basophiles or eosinophiles were noted. The resistant and susceptible groups varied between themselves, in the average percentage of eosinophiles, in the same manner and to the same extent before and during the infection. It was not possible in these studies to eliminate the contribution that other infections than that of *B. abortus* may have made on the variations in the total number or in the proportions of the different types of the cells."

The interrelationships of the blood cells of cattle in health and during *Brucella* infections, M. R. IRWIN and F. N. BELL. (Wis. Expt. Sta. and U. S. D. A.). (*Jour. Infect. Diseases*, 63 (1938), No. 3, pp. 263-268).—In studies of normal and *Brucella*-infected cattle made in connection with the work above noted, "the total number of leucocytes was positively, but not always significantly, correlated with the total number of erythrocytes. Only in infected, not at all in normal cattle, was there an appreciable association of the total number of white blood cells with the proportion of any type of these cells, and in such cattle with the percentage of but one type of cell, the monocyte. The proportions of the polymorphonuclear cells, lymphocytes, and eosinophiles were consistently and negatively intercorrelated, but with coefficients of correlation of varying magnitudes between the proportions of these different types of cells. Although in normal cattle the proportion of monocytes was not consistently correlated with that of any other type of leucocyte, in the infected animals it was negatively associated with the percentage of eosinophiles and in the group of susceptible animals with the polymorphonuclear cells. No significant coefficients of correlation were found of the percentage of basophiles with that of any other type of cell."

The relation between the presence of *Brucella abortus* and agglutinins in milk in cattle showing a blood agglutination titer of 1-200 or higher, D. B. MEYER and I. F. HUDDLESON. (Mich. Expt. Sta.). (*Cornell Vet.*, 28 (1938), No. 4, pp. 293-295).—Report is made of a cultural and serological study of the milk of 1,976 cows in 58 herds, representing 4 breeds and various crossbreds that extended over a period of 6 yr. An average of three milk samples was taken from each cow at intervals varying from 4 to 18 mo., although samples were taken from many cows but once. Of the total number of cows from which samples were taken 35.6 percent had shown a blood agglutination titer of 1:200 or higher. The blood samples were taken at an average interval of 4 mo.

The authors have found that in the majority of the animals studied *B. abortus* appears in the milk before agglutinins are detected therein. It may be present in the udder for a long period without the presence of agglutinins. *B. abortus* and agglutinins may occasionally be present in the udder in the absence of agglutinins in the blood. Approximately 12 percent of animals showing agglutinins in the milk in a titer of 1:100 or higher and positive milk culture become negative to

the former or the latter or to both. These data show that oftentimes there is little, if any, correlation between the presence of *Brucella* in the milk and the presence of agglutinins in the milk.

Resistance to Bang's disease of cattle that have passed through an artificially induced outbreak and recovered, B. A. BEACH. (Wis. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 374, 375).—In studies conducted, approximately 28 percent of 2 herds containing 14 and 7 cows, respectively, that were artificially infected with Bang's disease recovered as shown by the fact that the blood titers returned to normal. "Eighteen of 19 such cows proved resistant to an artificial *Brucella* infection that caused abortions in 36 of 47 controls (76 percent). One cow that had passed through a natural outbreak of Bang's disease and recovered is included in the 18 cows mentioned above. She behaved in exactly the same manner as the others, as far as could be determined."

Methods for the diagnosis and control of bovine mastitis, L. W. SLANETZ and J. NAGHSKI (*New Hampshire Sta. Tech. Bul.* 72 (1939), pp. 14).—In an attempt to determine the most practical and reliable tests for the routine diagnosis of mastitis a comparison was made of the value and efficiency of the strip-cup, bromothymol, Hotis, Burri agar slant, blood agar plate, microscopic examination of incubated sample, and Edwards' medium methods. The value of these tests for a mastitis control program and also for the detection of staphylococcal mastitis was considered. It is concluded that the strip-cup, bromothymol blue, and Hotis tests cannot be relied upon for an accurate diagnosis of infection. "The Burri agar slant method was approximately as efficient as the blood agar plate test, but it did not permit any observations on the hemolysis of the organisms, nor was it satisfactory for the isolation of pure cultures. The blood agar plate test when compared to the microscopic test detected 92 percent of the quarters and 97.2 percent of the cows infected with mastitis streptococci. The microscopic test is valuable for the detection of streptococcal mastitis. However, this test offers no information regarding the types of streptococci present and is of little assistance in the diagnosis of staphylococcal mastitis. The leucocyte count is not changed by incubation at 37° C. for 16 to 20 hr. Smears prepared from incubated samples can be used to determine the number of leucocytes per cubic centimeter. A combination of tests is necessary for a complete and accurate diagnosis of mastitis. The examination of milk samples by the blood agar plate method, microscopic test, and Edwards' medium proved very satisfactory for the detection of infected animals. Composite samples can be employed for the detection of mastitis infection. A program which provides for the periodical laboratory examination of samples and segregation with gradual replacement of infected animals appears necessary for the control of bovine mastitis."

A list is given of 34 references to the literature.

Bovine mastitis: Studies on a simplified method of diagnosis, T. L. JONES and F. W. SCHOFFIELD (*Canad. Jour. Compar. Med.*, 3 (1939), No. 2, pp. 54-57).

A method of preparing bovine udders for the study of the pathology of mastitis, O. W. SCHALM and C. M. HARING. (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 372, 373, figs. 2).—A description is given of a method whereby the entire bovine udder may be preserved permanently in formalin without material change. "By means of an electrically driven meat-slicer, it can be reduced to serial slices of from 3 to 5 mm. in thickness, making possible a minute examination of all portions of the gland. The method is particularly suitable for use in the collection and long-time preservation of normal and pathological mammary glands for teaching purposes."

Differential staining of sections of unpreserved bovine udder tissue affected with mastitis, W. T. MILLER and H. W. JOHNSON (*U. S. Dept. Agr. Circ. 514* (1939), pp. 4, pl. 1).—A description is given of a method by which unpreserved sections of bovine udder tissue can be stained to facilitate examination for indications of mastitis lesions. By this method the connective tissue is stained while the normal glandular tissue remains unstained, the presence and extent of the induration in the udders being demonstrated. A cross section of half an udder can be stained in this way without preliminary fixation. The intensity of the staining corresponds to the degree to which the disease has developed.

Pathology of calf pneumonia, W. T. S. THORP and E. T. HALLMAN. (Mich. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 365-371, figs. 16).—A report is made of 40 cases of calf pneumonia, gross and microscopic examinations of which were made for pathological changes. Of these 26 were studied bacteriologically. "Three variations were noted in the pathology of these cases: (1) An acute pneumonia, which progresses very rapidly, with the animal dying within several days, without evidence of any productive tissue changes but usually with a serofibrinous exudate filling the alveoli, (2) an acute pneumonia superimposed on a chronic bronchiolitis or chronic bronchopneumonia in which a large part of both lungs is consolidated, accompanied by a marked fibrinous pleurisy, and (3) the cases in which large numbers of abscesses and necrotic areas are present in the lung." That the pneumonia was consistently bilateral is considered well established. "It was shown by the gross and microscopic studies that the pneumonia usually begins in the apical lobes and that the pneumonia is consistently of longer duration in the left lung than in the right. Evidence in a large number of cases suggests that accompanying injury to the respiratory bronchioles is prior to a bronchitis of the small and large bronchi. Streptococci of the beta type and *Escherichia communior* were considered as probable causative agents in the disease."

Actinobacillosis in sheep, H. MARSH and H. W. WILKINS. (Mont. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 363, 364, figs. 3).—Report is made of a pyogenic infection of the face met with in Montana in the spring of 1937 in a band of some 2,000 ewes that had been fed hay during the winter. Of these about 60 died as an indirect result of the disease. The authors are led to conclude that the affection encountered is probably identical with that described by M. Christiansen in 1917* and others in Europe as caused by *Bacterium purifaciens*, apparently identical with *Actinobacillus lignierii*.

Chemical changes in the blood of swine infected with hog cholera, D. F. EVELLETH and L. H. SCHWARTZ. (Iowa State Col.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 411-417).—In the course of a study of experimental cholera in swine, the authors found certain changes in the blood chemistry, particularly in the phosphorus fractions and the total plasma calcium. The details of the work are given in eight tables. A list of 19 references to the literature is included.

The antibody response to swine influenza, C. T. ROSENBUSCH and R. E. SHOFF. (*Jour. Expt. Med.*, 69 (1939), No. 4, pp. 499-505, figs. 7).—It was found that antibodies that neutralize swine influenza virus became detectible in the serum of swine on the sixth or seventh day after infection with swine influenza. "Their appearance corresponded rather closely with clinical recovery. In swine with the milder filtrate disease, neutralizing antibodies did not appear

*Maanedsskr. Dyrlaeger, 29 (1917), No. 17, pp. 449-458, fig. 1.

until sometime between the seventh and tenth days. The maximum antibody titers ranged from 1:60 to 1:160 and were attained on from the fourteenth to the twenty-seventh days after infection."

The Moscow 2 strain of equine encephalomyelitic virus as compared with other strains of equine encephalitic viruses, B. F. HOWITT. (Univ. Calif.). (*Jour. Infect. Diseases*, 63 (1938), No. 3, pp. 269-286, figs. 5).—Report is made of a study of one (Moscow 2) of the four groups of equine encephalomyelitis viruses recognized as occurring in and received from the Union of Soviet Socialist Republics. "The eastern and western American and the Moscow 2 varieties of the virus of equine encephalomyelitis show distinct differences in their incubation periods, temperature curves, and in the clinical behavior in guinea pigs. All three strains infect the horse and the same types of experimental animals, although the rabbit is less susceptible for the western form than the guinea pig or the mouse. The eastern American variety may easily infect animals intracutaneously in high dilutions, while the others are less invasive by this route. The Russian form is most infective when given through the central nervous system and does not readily invade by other routes unless in comparatively large doses. Virus may be recovered from the blood serum and the tissues of animals infected with the American strains but not when infected with the Moscow 2, except from the central nervous system and occasionally from the salivary glands. The Moscow 2 strain may survive 7 weeks in the icebox when diluted in water but not if in saline. It also resists heating for 10 min. at 70° C. and can withstand freezing with solid CO₂. The eastern strain can withstand a higher hydrogen-ion concentration than the other two, but all three are destroyed by high acidity. The filtrability and also the viability of all three strains are affected by the type of diluting fluid employed. The Moscow 2 strain has a larger size than the other two, has not so far been cultivated in vitro nor on the chorioallantoic membranes of the developing chick, does not confer immunity on young guinea pigs born of immune parents, and is serologically and immunologically distinct from the American strains as shown by the complement fixation and the neutralization tests and by cross inoculation of immune animals. Brain tissue also contains certain intracytoplasmic inclusions peculiar to this form. The Moscow 2 strain may therefore be considered as a distinct variety of the group of viruses causing equine encephalomyelitis."

Infectious equine encephalomyelitis in Venezuela: Advance data concerning the causative agent, V. KUBES and F. A. RIOS (*Canad. Jour. Compar. Med.*, 3 (1939), No. 2, pp. 43, 44).—It is concluded from comparative studies conducted both in vivo and in vitro "that the Venezuelan encephalomyelitic virus is wholly different both from the American western virus and from the Argentine one, with which it has no immunobiological connection; that [it] also differs immunobiologically from the American eastern strain virus with which, however, it has some connection on account of its high virulence, pathogenicity, etc.; that the immunizing power of the protective vaccine made from autochthonous virus surpasses by far that of the American bivalent vaccine, prepared from both eastern and western viruses; [and] that the Venezuelan encephalomyelitic serum neutralizes the corresponding specific virus, not only in vivo, but also in vitro. Thanks to these studies the causative agent of infectious equine encephalomyelitis has been demonstrated for the first time in Venezuela. It is presumed that the agent in question constitutes a *sui generis* strain, different from the encephalomyelitis viruses described up to now. The writers are about to finish a complete report on these researches which will be published in due course of time."

Infectious equine encephalomyelitis: Mid-winter case, O. L. OSTEEEN. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 441, 442).—The death of a horse at Ocala in Marion County, Fla., on January 13, 1939 (in which locality mosquitoes may be active in January) from an affection that produced clinical symptoms resembling those of equine encephalomyelitis is reported. The presence of the eastern type of the virus of that disease was revealed by inoculation of guinea pigs and a typing test.

Marsh's disease, A. SAVAGE and J. M. ISA (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 431, 432).—Under the name Marsh's disease the authors record the appearance in Manitoba during the past 2 yr. of the peculiar disease of horses described by Marsh in 1937 from Montana (E. S. R., 78, p. 108).

Hookworm disease in dogs, J. W. LANDSBERG (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 389-397).—This contribution is presented with a list of 47 references to the literature.

The immunization of dogs against hookworm, *Ancylostoma caninum*, by subcutaneous injection of graded doses of living larvae, G. F. OTTO and K. B. KERE (*Amer. Jour. Hyg.*, 29 (1939), No. 1, Sect. D, pp. 25-45, figs. 4).—The authors conclude that not only does the phenomenon of actively acquired immunity operate in the host parasite relationship of the canine host and the hookworm *A. caninum*, but it is apparently by far the most important natural means of host control of the infection. They were unable to find any conclusive evidence that the so-called age resistance is an entity in itself.

A comparative study of distemper inclusions, R. G. GREEN and C. A. EVANS. (Univ. Minn. and U. S. D. A.). (*Amer. Jour. Hyg.*, 29 (1939), No. 2, Sect. B, pp. 73-87, figs. 4).—The authors have found that canine distemper and epizootic fox encephalitis can be differentiated with certainty by their respective inclusion bodies. The virus of canine distemper produces morphologically identical inclusion bodies in dogs, foxes, minks, and ferrets, but there are minor differences in the distribution of inclusions in the several species. A list of 17 references is included.

A virus disease of cats, principally characterized by aleucocytosis, enteric lesions, and the presence of intranuclear inclusion bodies, W. D. HAMMON and J. F. ENDEES (*Jour. Expt. Med.*, 69 (1939), No. 3, pp. 327-352, pl. 1).—A description is given of an acute, highly fatal epizootic disease of cats characterized by fulminating and extreme leucopenia involving all types of "white blood cells, aplasia of the bone marrow, including both the granulocytic and the erythrocytic series and occasionally the megakaryocytes, aplasia of lymphoid tissue, and characteristic intranuclear inclusion bodies in the cells of the intestinal mucosa and in certain cells of the spleen, lymph nodes, and bone marrow. The infection has been induced in healthy cats by means of bacteria-free filtrates of emulsions of the spleen of infected animals. Collateral evidence supports the conclusion that the disease is due to a virus. The pathogenicity of the infectious agent has proved thus far to be strictly limited to the natural host."

Botulism in foxes, N. J. PYLE and R. M. BROWN (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 436-439).—The poisoning of foxes fed on spoiled fish found to contain *Clostridium botulinum* type A toxin is reported.

Anthrax in farm-raised mink in Oregon, C. R. HOWARTH and L. SEGNETTI. (Oreg. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 433, 434).—A sporadic outbreak of anthrax in mink in Oregon is reported.

Coccidiosis in muskrats influenced by water levels, J. E. SHILLINGER. (U. S. D. A.). (*Jour. Wildlife Mgmt.*, 2 (1938), No. 4, pp. 233, 234).—It is pointed out that coccidiosis seldom becomes serious in muskrats in normal con-

ditions, but that in partially dried marshes where the droppings are not washed away heavy infestations take place. "Lesions found in muskrats affected with coccidiosis may be described as grayish-white granular areas in the liver and inflammation in the small intestine. According to the writer's observations, the enteritis may not be as important as the destruction of liver tissue. Although either of these lesions alone, when sufficiently extensive, may cause death, most of the deaths observed seemed more properly ascribed to the coccidiosis of the liver." It is thought that muskrat coccidiosis can be controlled by manipulation of the water level where this is feasible.

Coccidiosis of the chicken, with special reference to species, W. T. JOHNSON (*Oregon Sta. Bul. 358 (1938), pp. 33, figs. 15*).—This bulletin, which has been written by the widow of the late author from rough manuscript notes and tables prepared over a considerable period of research at the station, describes and deals with six species of coccidia infecting the chicken. These are *Eimeria tenella* Raill. and Lucet, *E. maxima* Tyzzer, *E. acervulina* Tyzzer, *E. mitis* Tyzzer, *E. praecox*, and *E. necatrix*, the last two of which are described as new. The contribution, with a list of 21 references to the literature cited, is summarized as follows: "The average measurements in microns of 50 sporulated oocysts for each species were 13.7 by 15.0 *E. mitis*, 13.8 by 18.0 *E. acervulina*, 17.5 by 23.7 *E. tenella*, 20.6 by 23.8 *E. praecox*, and 22.9 by 30.4 *E. maxima*. The average measurements in microns of 9 schizonts of *E. necatrix* selected from a large number were 49.2 by 63.1. *E. tenella* proved pathogenic with 24 hr. or less sporulation, *E. acervulina* in 18 to 24, *E. mitis* and *E. praecox* in 24 to 36, and *E. maxima* in 36 to 48. The minimum prepatent period observed for *E. praecox*, *E. acervulina*, *E. mitis*, *E. maxima*, and *E. tenella* was 4, 4, 5, 6, and 7 days, respectively. Self-limitation of infection occurred with *E. mitis*, *E. acervulina*, *E. praecox*, *E. maxima*, and *E. tenella*. Immunity or a high degree of resistance was established against *E. mitis*, *E. acervulina*, *E. praecox*, *E. maxima*, and *E. tenella*.

"Distinct susceptibility was demonstrated to *E. tenella*, *E. maxima*, *E. praecox*, *E. acervulina*, and *E. mitis* in the same fowl, inoculated in the order named. A second fowl, inoculated in reverse order, showed distinct susceptibility to all except *E. tenella*, which was probably due to previous accidental infection with this species. With large dosage, *E. necatrix* and *E. tenella* showed extensive hemorrhage from the small intestine and ceca respectively; *E. maxima* showed slight hemorrhage and considerable viscid mucus from the small intestine; [and] *E. mitis* and *E. praecox* showed slight and moderate amounts, respectively, of viscid mucus from the small intestine. Laboratory-reared fowls between 2 and 3 yr. of age were distinctly susceptible to *E. mitis*, *E. acervulina*, *E. praecox*, *E. maxima*, and *E. tenella*. Infection was accompanied by loss of appetite and markedly abnormal small-intestine feces when inoculated with *E. acervulina* and *E. maxima*. The data offer discouragement to the practice of raising fowls to maturity free of coccidiosis."

Two new *Salmonella* types isolated from fowls, P. R. EDWARDS and D. W. BRUNER. (Ky. Expt. Sta.). (*Jour. Hyg. [London], 38 (1938), No. 6, pp. 716-720*).—Studies of cultures of *Salmonella* led to recognition of the two species here described as new. The first of these was isolated from a 3-weeks-old poult which came from a turkey farm in Minnesota and is named *S. minnesota*. Its antigenic formula is XXI: 6-12-13-14. The second species, to which the name *S. worthington* is given, was isolated from a young turkey which came from a hatchery at Worthington, Minn. (hence the specific name), and also from a chick, the origin of which is unknown. Its antigenic formula is I XIII XXIII: 10-12-13-14.

Avian tuberculosis infections, W. H. FELDMAN (*Baltimore: Williams & Wilkins Co., 1938, pp. IX+483, figs. 109*).—Following an introductory discussion, the several chapters of this work consider the biologic characteristics of *Mycobacterium tuberculosis avium*; isolation and culture; diagnosis in chickens, laboratory procedures for demonstrating tuberculous infections in mammals and fowl; the pathologic anatomy of tuberculosis in chickens; experimental tuberculosis in chickens; pathogenicity of avian tubercle bacilli for fowl other than chickens, certain mammals other than man, cattle, swine, and human beings; tuberculin and the tuberculin test; and dissemination and control of avian tuberculosis. Lists of references to the literature accompany the several chapters.

The occurrence of avian tubercle bacilli in dressed poultry, W. H. FELDMAN (*Jour. Infect. Diseases, 63 (1938), No. 3, pp. 332-336, fig. 1*).—A report is made of the results of examinations of spleens of 125 dressed poultry by culture methods for tubercle bacilli. Four of the spleens examined were found to contain tubercle bacilli. Each strain of the micro-organism secured was identified by tests for pathogenicity. These findings indicate that "dressed poultry originating from districts where tuberculosis of fowl is prevalent may harbor avian tubercle bacilli of standard virulence even though recognizable morbid changes be absent, and tubercle bacilli may be present in apparently normal-appearing fowl reared in an infective environment. These findings suggest that the correction of the situation consists in rearing fowl in a nontuberculous environment. No practical method of post-mortem inspection will disclose the presence of tubercle bacilli in the absence of gross lesions."

Poultry sanitation and disease control, B. F. KAUFF and R. C. SURFACE (*Chicago: Authors, 1939, pp. 420, figs. 82*).—This practical work, intended to be a complete guide to sanitation and treatment of diseases of poultry, is presented in 21 chapters.

Sulfured soil for poultry yards, M. W. EMMEL (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc., 94 (1939), No. 4, pp. 409, 410*).—The findings in experiments on various uses of sulfur in connection with poultry raising, conducted during the past 3 yr., have shown sulfured soil to be of assistance in the control of diseases met with on premises in which birds must be confined in the same yards continuously. Commercial flour sulfur, consisting of ground run-of-mine sulfur grading 90 percent through 80-mesh screen, obtainable at about half the price of commercial flowers of sulfur, was used. It was broadcast over the surface of the soil at the rate of 800 lb. per acre and mixed with top soil by the use of a rake. The action of soil bacteria on sulfur produces sulfuric acid, which renders the soil acid in reaction, tests having shown that approximately 2 to 2½ mo. are required for the maximum acidity of a pH of 2.0 to 2.2 to be reached in surface soil. Soils sulfured to a depth of 6 in. remain at the maximum acidity for 1 yr., at the end of which free sulfur could still be found. The increased acidity results in the disappearance of all of the intermediate hosts of poultry tapeworms, including snails, slugs, earthworms, etc., whose life cycle definitely is associated with the soil. The life cycle of the common roundworm, whose egg must undergo incubation over a period of time on the ground, apparently is retarded. Pathogenic bacteria probably do not remain viable as long as the pH values of sulfured soil as in cases in which the soil is not so treated.

Paratyphoid and trichomonas infection in pigeons, W. E. NIEMEYER (*Jour. Amer. Vet. Med. Assoc., 94 (1939), No. 4, pp. 434, 435*).—The author records the isolation of *Trichomonas columbae* and *Salmonella typhimurium*—type IV variant—from diseased pigeons in southern California.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the California Station] (*California Sta. [Blen.] Rpt. 1937-38, pp. 81-83, 92-94*).—Briefly noted under the heading of improving the mechanics of crop production are a nutcracking device whereby walnuts are carried over a circular slotting saw, filled from jets in a guide rib with explosive gas mixture, and dropped through a burner so that the meats fall into a center container within a larger receiver for exploded shell, the percentage of whole or half meats being much greater than in hand cracking; a new seed-bean thresher; development of sugar beet machinery; new citrus dusting equipment; orchard-heating problems (fuel, fueling, and burner studies); blowers for frost protection; precooling truck crops for eastern shipment; and poultry house cooling.

[Agricultural engineering investigations by the South Dakota Station], R. PARRY (*South Dakota Sta. Rpt. 1938, pp. 6, 7*).—Progress results are briefly presented of investigations on field machinery hitches for tractors and large horse teams, corn harvesting machinery, protective covering and the life of steel fence posts, and rammed earth for farm building walls.

Surface water supply of the United States, 1937.—Part 5, Hudson Bay and upper Mississippi River basins (*U. S. Geol. Survey, Water-Supply Paper 825 (1938), pp. VIII+334, pl. 1*).—This report presents measurements of flow made on streams in these basins during the year ended September 30, 1937.

[Water control investigations at the Everglades Substation], B. S. CLAYTON and J. R. NELLER (Coop. U. S. D. A.). (*Florida Sta. Rpt. 1938, pp. 154-156*).—Records on cost of pumping were continued, also those on effect of water table depths on crop yields; evaporation and transpiration from sugarcane, saw grass, bare soil, and mulched ground; the subsidence of peat soils; and the surface irrigation of sugarcane.

Public Roads, [March 1939] (*U. S. Dept. Agr., Pub. Roads, 20 (1939), No. 1, pp. [1]+19+[1], figs. 17*).—This number of this periodical contains data on the status of Federal-aid highway, secondary or feeder road, and grade-crossing projects, all as of February 28, 1939, and the following articles: A Study of Sand-Clay-Gravel Materials for Base-Course Construction, by C. A. Carpenter and E. A. Willis (pp. 1-12, 16, 17); and Simplified Computation of Hydrometer Test Data for Soil, by E. S. Barber (pp. 13-16).

New building materials, C. B. JENNI. (*W. Va. Univ. (W. Va. Univ. Bul., 38. ser., No. 3-II (1937), pp. 108-114*).—The author briefly outlines the nature, method of manufacture, and uses of several of the newer building materials, such as fiber building boards, insulating materials, cellulated clay, gypsum products, fabricated asbestos-cement compositions, concrete including prefabricated forms, glass including translucent masonry blocks, synthetic plastics, and metals.

The use of electricity in agriculture, L. J. SMITH, H. N. COLBY, and H. L. GAEBER (*Washington Sta. Bul. 368 (1938), p. 10*).—Studies on comparative cost of cooking with various sources of heat, cost of drying hay, cost of electric heating of water, placement of heating cables in hotbeds, and the use of electric light in stimulating egg production are very briefly reported.

Electric milk refrigeration at the farm, J. EL. NICHOLAS and R. U. BLASINGAME (*Pennsylvania Sta. Bul. 375 (1939), pp. [2]+38, figs. 29*).—Detailed air temperature and performance data concerning several milk-can cooling arrangements electrically refrigerated were obtained in the milk houses of four farms in the warmest part of Pennsylvania (highest 24-hr. average milk house air temperature 83.4° F.)

Milk cools more rapidly and uniformly in farm electric coolers when the bath water is agitated, and agitation of the cooling water should continue for at least 1 hr. The cooling water should be agitated during the cooling of both morning and evening milk. The average temperature of the evening milk after 12 hr. of cooling with sufficient water may be as low as 33.1° and as high as 40.1°, depending on the amount of refrigeration initially available and the setting of the thermostat. When agitation with sufficient water is employed the average temperature of the morning milk after 1 hr. of cooling may be as low as 42.8° and as high as 49.3°, depending on the amount of refrigeration initially available. A can of milk cools more in the first hour than it does in 11 succeeding hours. With sufficient water level but no agitation of the bath the average temperature of milk after 1 hr. of cooling was 52.5°. When the milk in the cans was stirred and the bath water was not, the average temperature of the milk was not below 50° at the end of the first hour even with a large ice bank on the coils at the start. Milk cools more rapidly under the same thermostat limits with a water:milk ratio of 5 than with a ratio of 3, and more rapidly when some ice is on the coil. The ice maintains the bath water at a low temperature during the first hour of cooling when milk transfers the greatest portion of its heat. If the bath water is agitated and the cans have insufficient water for complete submersion of the milk, the portion which is above the water level will cool slowly. When raining, spraying, or sprinkling of the bath at milk height is practiced, with incomplete submersion of the cans, the average milk temperature is below 50° in the first hour. When a large ice bank is used the water:milk ratio may be small. A pound of ice in melting and warming to 38° is as effective in cooling milk as 150 lb. of water increasing in temperature from 37° to 38°. Milk cools most rapidly when a large ice bank is used with sufficient water level and the water is agitated. If sufficient water and agitation with or without ice on the coil are used the average temperature of the milk is below 50° in the first hour of cooling.

The evening load will warm on the outside of the cabinet in an 82° to 85° room temperature approximately as much as it will if it remains in the cabinet during the cooling of the morning load. At the end of an hour the evening load standing unprotected on the floor in the morning in an 82° to 85° room will average from 12° to 51° colder than the morning milk cooled 1 hr.

Performance coefficients were determined under various operating conditions, the lowest value obtained being 2.11 kw.-hr. per degree Fahrenheit per gallon, the highest 3.09. In an appendix it is shown by calculation of thermal relations that some ice on the coils at the beginning of cooling will give the best results. An equation for heat transfer through ice under the conditions of milk cooling equipment is also set up and integrated.

The refrigerating data book, I (*New York: Amer. Soc. Refrig. Engin., [1939], 4. ed., vol. 1, pp. [91]-527, figs. [292]*).—This reference book, previously revised at from 2- to 3-yr. intervals, has now been divided into two volumes on refrigerating principles and machinery and on applications of refrigeration, respectively. The first volume, here noted, is scheduled for revision each 4 yr. from 1939, the second for revision each 4 yr. from 1941.

Of this first volume, part 1 takes up principles of refrigeration, basic processes, and data; part 2, refrigerants; part 3, heat flow and insulation; part 4, air conditioning; part 5, properties of foods; part 6, domestic-commercial machinery; part 7, industrial machinery; and part 8, controls and power.

Effect of cleaning seed cotton on lint quality and ginning efficiency, F. L. GERDES, A. J. JOHNSON, and C. A. BENNETT. (Coop. Ga. Coastal Plain, La., Miss., and N. C. Expt. Stas., et al.). (*U. S. Dept. Agr., Tech. Bul. 663 (1939)*,

pp. [2] + 64, pls. 9. *figs. 13*).—With hand-picked cottons of wide range of foreign-matter content and staple length, the authors tested a huller front and extractor-feeder with a plain stand, a cylinder cleaner and extractor, and a combination of the cleaner and extractor with a huller stand. The cottons used were practically all below 12 percent in moisture content and were mostly of $1\frac{1}{32}$ -in. staple or less. Cleaning tests on hand-picked and snapped cottons with equipment ranging from minimum to elaborate combinations of cleaning and extracting devices with a huller gin were also made.

Bale-weight decreases due to cleaning and extracting were not so great as the weights of foreign matter removed. The "fluffed" cotton from the cleaning machines could be ginned closer, offsetting part of the trash-weight loss by increased weight of the ginned lint.

Improvements of grade as a result of cleaning the seed cotton by the various methods were closely related to foreign-matter removal by the cleaning units. Greater enhancements in grade generally resulted with the shorter than with the longer cottons and with the cottons of higher than with those of lower foreign-matter content. The measurements of brilliance of the samples gave relationships generally similar to those shown for grade. When the cleaner and extractor were employed singly or in tandem on the cottons of higher foreign-matter content, the quality of the lint ginned with a loose seed roll was increased by an average of one-half of a grade with the shorter and almost one-third of a grade with the longer cottons. The beneficial effects of these units were less with the tight than with the loose seed roll. When cleaning the cotton of low foreign-matter content, changes in grade for the longer staple cotton were negligible, but for the shorter staple cottons the set-ups with the extractor showed some small enhancements. For the third series of tests the improvements from cleaning for the snapped cottons were almost three times those for the hand-picked cottons and increased with the additional cleaners and extractors from 0.5 of a grade with the six-cylinder cleaner set-up to 1.6 grades with the set-up having three cleaners and two extractors. Although the cleaners and extractors greatly improved the grade of lint ginned from the snapped cottons, the most elaborate combination gave an average grade still about one-third of a grade lower than the average grade of the lint ginned from the picked cottons handled by the simple control set-up.

The grade of lint was not affected by increasing or decreasing the speed 100 revolutions per minute from the manufacturer's recommended speed with either the extractor-feeder or the air-line or out-of-air cleaners. The use of air-line and out-of-air cleaners gave similar grade results.

Differences in ginning time between uncleaned and cleaned, picked cotton were generally small except when, in a few instances, the cleaning units so fluffed the cotton that adequate quantities were not fed to the seed-roll box. With the snapped cotton the use of an extractor caused reductions in the ginning time that averaged about 40 percent. The removal of burs made possible a continuous gin-stand operation. Energy consumption of the gin stand showed only small increases when cleaning the picked cotton but indicated economies of 16 percent or larger when the snapped cotton had been extracted.

Industrial waste treatment processes and plant design, E. F. ELDRIDGE (*Mich. Engrin. Rpt. Sta. Bul. 82* (1938), pp. 103, *figs. 31*).—Part 1 deals generally with industrial waste pollutions. Parts 2 to 11 take up, respectively, beet sugar, milk products, metal treating and plating, canning, meat packing, tannery, textile, laundry, and pulp and paper mill wastes and the effect of industrial wastes in sewage treatment plants.

Insofar as the necessary information has been available, the present bulletin takes up not only the treatment processes but also the structures and equipment required for full-scale practical operation of the process. "In some cases the treatment processes are so . . . defined as to allow exact drawings and dimensions to be given. Even cost data . . . [are] possible in a few cases."

AGRICULTURAL ECONOMICS

[Articles and notes on agricultural economics] (*Jour. Farm Econ.*, 20 (1938), No. 4, pp. 741-869, figs. 6).—Included are articles as follows: Some Fundamentals of Agricultural Policy, by O. B. Jesness (pp. 741-752) (Univ. Minn.); Agricultural Planning and the Agricultural Economist, by O. V. Wells (pp. 753-764) (U. S. D. A.); Theme of Plant and Animal Destruction in Economic History, by C. O. Sauer (pp. 765-775) (Univ. Calif.); Intensity and Land Rent—An Overlooked Aspect of Rent Theory, by C. H. Hammar (pp. 776-791) (Univ. Mo.); Price Discrimination for Agricultural Products, by G. Shepherd (pp. 792-806) (Iowa Expt. Sta.); Lessons from Public Control in Milk Marketing, by J. M. Tinley (pp. 807-822) (Univ. Calif.); and Economic Relationships of Public Lands and Privately Owned Grazing Lands in the Western States, by M. H. Saunderson (pp. 841-853) (U. S. D. A.). Notes are included as follows: A Special Case Consumption-Ratio Formula for the Determination of a Limit on the Price Incidence of a Duty, by C. F. Wells and A. M. DuPré, Jr. (pp. 854-856), and Joint Stock Land Banks in Retrospect, by V. W. Bennett (pp. 857-865) (both U. S. D. A.); and How Should Farm Management be Taught? by W. G. Murray (pp. 865-869) (Iowa State Col.). Also included is the reply to W. A. Morton (Univ. Wis.) by H. Schultz and the rejoinder to this reply by Morton, on the Economic Theory of the Wisconsin Tariff Research Committee (pp. 823-840).

[Investigations in agricultural economics by the California Station, 1936-38] (*California Sta. [Buen.] Rpt. 1937-38*, pp. 113-122).—In addition to results previously noted, some general findings are reported for studies of the number of cattle and shipments into and from the State of stockers, feeders, and finished cattle; of the production, prices, marketing outlets, etc., of prunes; of the shipments and prices of canned asparagus, and results of the new developments in the financial structure of the Poultry Producers of Central California.

[Investigations in agricultural economics by the Florida Station, 1937-38] (*Florida Sta. Rpt. 1938*, pp. 35-38).—Included are tables by H. G. Hamilton and C. V. Noble showing the principal reasons why farmers' cooperative associations in Florida have ceased to operate and the proportion of the total State volume of leading fruit and vegetable crops sold through cooperative associations, 1936-37, and a table by Z. Savage and Noble showing the average costs and returns by years, 1932-33 to 1936-37, for late orange groves from 15 to 17 yr. of age.

Current Farm Economics, [February 1939] (*Oklahoma Sta., Cur. Farm Econ.*, 12 (1939), No. 1, pp. 32, figs. 9).—Included are the usual tables of indexes of prices, demand deposits, and purchasing power of Oklahoma farm products, and articles on The Agricultural Situation, by M. Hill and A. L. Larson (pp. 2, 3); The Cash Farm Income Situation, by P. Nelson (pp. 3-7); Agricultural Cooperation in Oklahoma, by A. L. Larson (pp. 8-12); The Reciprocal Trade Agreement Program in Relation to Southern Economy, by R. D. Thomas (pp. 12-18); and Cotton Sold in the Seed in Oklahoma, by M. Hill and P. Nelson (pp. 19-27).

Local government in two rural Ohio counties, H. R. MOORE. (Coop. U. S. D. A.). (*Ohio Sta. Bul.* 597 (1938), pp. 48, figs. 6).—Analysis is made of the receipts by sources and expenditures for different purposes by the counties, townships, school districts, and villages in Noble County, representative of the southeastern hill section of the State, and Putnam County, representative of western Ohio. The data for the counties and townships cover the period 1932-36, inclusive, those for school districts, from 1931-32 to 1935-36, inclusive, and those for villages, 1932-34, inclusive, and 1936. The various receipts and expenditures and their trends are discussed.

Kansas oil property taxation in relation to farm taxes, L. F. MILLER (*Kansas Sta. Circ.* 195 (1938), pp. 27, figs. 6).—Data as to total oil production for the tax year March 1935-February 1936, gravity of oil, assessed value of leasehold and equipment, and price of oil were obtained from the records of county clerks, assessors, and superintendents of schools, and the State Corporation Commission. The oil industry in the State and the present method of assessing oil-producing properties are described, and comparison is made with tax rates on such properties in other States. Comparison is made of the value of the product and assessed value of producing property and the average tax rates on oil and agricultural property in the State. Proposed bills, 1915-37, for a severance tax and the proper relationship of a severance tax to present taxes, methods of allocating a severance tax to taxing units, the incidence of such a tax, and its probable effect on oil production, conservation of oil, and probable financial results of such a tax are discussed. "In Kansas, the tax per \$100 of gross income from oil-producing property in 1936 was \$1.50, while on \$100 of gross income from farm property the tax was \$8.04. . . ."

"It seems that little, if any, of a severance tax in Kansas would be shifted to the consumer of the refined products of the crude oil. This would tend to be true because the speculative nature of crude oil production would tend to prevent reduction in the supply and, therefore, any increase in price. With no appreciable reduction in the supply, a severance tax would have little effect on the conservation of oil.

"The volume of production, the price of crude oil, and the tax rate, all affect the yield of a severance tax. The revenue from a 3-percent severance tax in Kansas would be \$2,625,000 if the total production were 70 million barrels and the average price for crude oil was \$1.25 per barrel."

Agricultural credit, G. LUNDY (*South Dakota Sta. Rpt.* 1938, pp. 4, 5).—A table showing the number of farm foreclosures instituted in the organized counties in 1936 and 1937, and a brief statement as to the reduction in the acreage mortgaged and debt per acre from 1930 to 1935 in five counties being studied in cooperation with the W. P. A., are included.

Michigan farm business summary—1937, H. A. BEER and C. O. MAY (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 3, pp. 215-225, figs. 5).—The farm accounts for 1,163 farms for 1937 are summarized in tables showing by type-of-farming areas the acreages, investments, cash receipts and expenses, changes in inventory, net cash and farm income, operator's labor and management wage, percentages of land in different crops, numbers, kinds, and returns from livestock, and labor, machinery, and improvement costs. Other tables and charts make comparisons of the financial returns on Michigan farms 1932-37, and show the number and percentage of farms receiving different operator's labor and management wages in 1937 and percentages of different items of total investments, receipts, and expenses.

Foreign Agriculture, [March 1939] (*U. S. Dept. Agr., Foreign Agr. Serv., Foreign Agr.*, 3 (1939), No. 3, pp. 85-126, figs. 7).—Included are articles on The

Hog Industry in France, by H. E. Reed (pp. 87-98), and The Land Problem in Mexico, by C. H. Barber (pp. 99-120); and notes on recent developments in foreign agriculture as follows: More government aid to British agriculture expected (pp. 121, 122), government of Java intervenes to prevent collapse in kapok prices (pp. 122-124), Venezuela's National Coffee Institute reorganized (pp. 124, 125), German-Irish trade agreement extended (pp. 125, 126), and Poland adopts grain-storage program (p. 126).

Contributions from Iowa Corn Research Institute (*Contrib. Iowa Corn Res. Inst. [Iowa Sta.], 1 (1939), No. 2, pp. 163-207, 228-256, 259-279, figs. 15*).—Included are papers with discussions presented at the conference held at Ames, Iowa, May 9 and 10, 1938, and participated in by 60 representatives of wet milling, dry milling, and fermentation industries, farmers' organizations, the Federal Government, and research organizations of various States. In addition to the address of welcome by C. E. Friley and several papers noted elsewhere in this issue, formal papers were presented as follows: The Probable Effect of the 1938 Agricultural Adjustment Act Upon the Supply and Price of Corn: An Introductory Analysis, by O. V. Wells (pp. 165-174) (U. S. D. A.); The Probable Effect of the Agricultural Adjustment Act for 1938 on the Wet-Milling Industry, by F. J. Hosking (pp. 177-190); The Use of Corn in the Fermentation Industries, by L. M. Christensen (pp. 192-201); Effect of the 1938 Agricultural Adjustment Act Upon the Agricultural Industry, by C. Gregory (pp. 202-207); The Effect of Imports Upon the Agricultural and Industrial Demand for Corn: Introductory Analysis, by A. E. Taylor (pp. 228-236); The Effects of Tapioca and Sago Imports Upon the Corn Wet-Milling Industry, by A. E. Staley, Jr., (pp. 237-246); Analysis of the Interests of Dry Millers, by H. Hunter (pp. 248-256); Barriers to Trade Resulting From State Regulations, by F. V. Waugh (pp. 259-262) (U. S. D. A.); and The Effect of Food Laws on Dextrose Utilization, by J. B. Newman (pp. 263-268).

An economic study of farm organization and operation in the High Plains cotton area of Texas, B. H. THIBODEAUX, C. A. BONNEN, and A. C. MAGLE. (Coop. U. S. D. A.). (*Texas Sta. Bul. 568 (1939), pp. 75, figs. 4*).—This is the first of a series of bulletins based on a farm management study of 127 to 141 farms in Dawson, Lynn, Lubbock, Hockley, and Lamb Counties each year 1931-35, inclusive. Detailed financial reports were kept by cooperating farmers with the assistance of a field man, and supplemented by data as to practices used in the crop and livestock enterprises. The topography, soils, climate, agriculture, etc., of the area are described.

The average operator's earnings for the 5 yr. were \$223 in 1931, \$124 in 1932, \$1,808 in 1933, \$254 in 1934, and \$980 in 1935. Approximately 63 percent of the variations in earnings in 1931 and 1932 were caused by six factors, size of farm, percentage of land in cotton, number of produce animals per 100 acres, acre yield of cotton, return per \$100 feed fed to produce livestock, and productive work days per man. Operator's earnings ranged from —\$487 on farms below the average in all factors to \$1,090 for those above the average in all factors. Size of farm generally was not closely associated with earnings, the net effect of adding 1 acre being to lower the earnings by 54 ct. One percent increase in proportion of farm land in cotton increased earnings \$12.80, and an increase of 1 lb per acre in yield increased earnings \$3.62 on an average. Earnings were lowered on an average by \$7.18 for each animal unit of produce livestock per 100 acres of farm land, and increased \$1.67 by each increase of \$1 in the average returns per \$100 worth of feed fed. Each additional day of productive man labor, excluding harvesting, was associated with an increase of \$3.15 in earnings.

The tobacco industry in Puerto Rico, C. E. GAGE (*U. S. Dept. Agr. Circ. 519* (1939), pp. 54, figs. 18).—The physiography and climate of the island are described. The types of tobacco grown, cultural practices, diseases, insect pests, grading, preparation for marketing, marketing channels, possible marketing reform, exports and imports of unmanufactured tobacco, tobacco manufactures and consumption, and need for research are discussed.

Trends of yield in major wheat regions since 1885, I, II, M. K. BENNETT (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 14* (1937), No. 3, pp. [2]+69-102, figs. 10; 14 (1938), No. 6, pp. [2]+223-261, figs. 17).—This contribution is presented in two parts.

Part 1, General considerations and rising trends.—This study analyzes the specific influences that seem to have determined the trends of wheat yield in the five regions of rising trend. Initial levels of yield seem to have been relatively unimportant. Some of the trend-increase in all regions resulted from "accidental" influences—either the sequence of stretches of bad and good weather for wheat or statistical inaccuracies, or both. In three regions increase of yield was hampered by internal shifts of acreage, but in two the shifting was favorable to yields. The major part of the trend-increase in yield in all five regions seems assignable to man-made improvement of agricultural technics. Wider use of fertilizers and the development and spread of improved wheat varieties seem to have dominated.

Part 2, Irregular, stable, and declining trends.—This study deals similarly to part 1 with trends in nine other regions. Measured by weighted 9-yr. moving averages of annual data, the trends were irregular in four regions and about horizontal in two, while in three they declined. With rough allowance for statistical inaccuracies and vagaries of the weather, it appears that over the major and more recent part of the past half-century the basic trend was upward in two regions, broadly horizontal in four, and downward in three.

In a "world" made up of all these 14 regions and not including Russia and China, the basic trend of yield was upward in the first part of the past half-century and downward in the second part. Agricultural technic has improved with only temporary or local interruption and rapidly enough to overcome persistent drain on soil fertility in most parts of the world. The reversal of trend rests heavily upon the altered distribution of wheat acreage, with large increases mainly in essentially low-yielding territory.

The world wheat situation, 1937-38: A review of the crop year, J. S. DAVIS (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 15* (1938), No. 4, pp. [2]+181-258, figs. 23).—Scarcity continued to mark the crop year 1937-38, but it was met without severe strain and was significantly tempered by increasing assurance of large wheat crops in 1938. In consequence, the course of wheat prices was downward, in striking contrast to the advances through most of 1936-37. A normal harvest in the United States, the first in 5 yr., accounted for most of the substantial net increase in world wheat production in 1937. Severe crop damage in Canada and Argentina and mediocre out-turns in many other countries were offset by large crops in Australia, Rumania, Italy, and several minor producers. The Union of Soviet Socialist Republics, from big grain crops, exported more than for several years past. International trade in wheat and flour was light, net exports of net-exporting countries totaling only 553,000,000 bu.

Wheat utilization, in the aggregate, was held down by fairly high wheat prices and in many countries by government measures, old and new. The world carry-over consequently rose to a figure equal to the average in the presurplus period. Most of the increase was in the United States and in Germany. Even where

carry-overs were below average they were generally ample in view of the abundance that was in sight by the middle of 1938.

World wheat survey and outlook, September 1938 [and January 1939], H. C. FARNSWORTH and H. WORKING (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 15 (1938), No. 1, pp. [2]+1-47, figs. 10; 15 (1939), No. 5, pp. [2]+259-296, figs. 9).*—These numbers continue the series (E. S. R., 79, p. 408).

Shipping and freight rates in the overseas grain trade, V. D. WICKIZER (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 15 (1938), No. 2, pp. [2]+49-120, pl. 1, figs. 15).*—World trade in grain is still the most important employment for that branch of shipping devoted to transport of bulk goods which must move at low cost. Due largely to advances in technology and organization, the trend of ocean freights has been downward for decades, especially in relation to commodity prices generally. Important interruptions to this trend occurred during the World War and in briefer periods before and since, most recently in 1936-37.

Rate variations over briefer stretches of years and fluctuations over periods of months continue to influence the course of trade and international price spreads in grain. Except temporarily, such influences are now overshadowed by those exerted by nationalistic policies which affect agriculture, commerce, and shipping directly and indirectly.

Wheat futures prices and trading at Liverpool since 1886, H. WORKING and S. HOOS (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 15 (1938), No. 3, pp. [2]+121-180, pls. 2, figs. 2).*—The average price of all wheat imported into the United Kingdom seems the most broadly representative of the various price series. For short-period comparisons, prices of Liverpool wheat futures are best of all. Comparisons among these series show that the futures prices are representative of the general level of prices of British imported wheat and are useful for long-period as well as for short-period comparisons. The history of the Liverpool futures contract is one of progressive improvement. A prime objective in the evolution of the contract has been adaptation to the needs for hedging wheat in channels of international trade. "From the standpoint of volume of trading or volume of open contracts, the Liverpool futures market ranks far below Chicago and Winnipeg. It is pre-eminent in balanced reflection rather than in generation of price influences. A large proportion of its business originates with hedgers and with speculators who take a long view of the price outlook. Although peculiarly vulnerable to 'corners' and 'squeezes,' Liverpool has succeeded remarkably in avoiding such manipulation."

The crab apple, commercially considered, E. H. BJORNSETH (*Michigan Sta. Quart. Bul., 21 (1939), No. 3, pp. 191-202, figs. 4).*—This study in Allegan County was made in cooperation with the Fennville Fruit Exchange. Tables and charts are included and discussed.

The gross income from crab apples was 4.4 percent of the total gross income from the sale of all kinds of fruit by the exchange. No other fruit crop yielded as regular an income as crab apples. The percentage of U. S. No. 1 crab apples was 72.5 in the period 1931-33 for all members of the exchange and 86.7 in 1934-36 for the principal crab apple growers, as compared with 55.9 for pears, 52 for peaches, and 40 for apples. Prices for crab apples were more or less independent of those for other fruits, following somewhat the prices of other fruits but with less variation from year to year. The total market cost for crab apples varied from 29 ct. per bushel in 1932 to 38½ ct. in 1936. The net income per acre for crab apples was \$44.50 in 1935 and \$111 in 1936, and averaged \$63.66 for the period 1931-36. The demand for crab apples is about the same from year to year, and consequently increase of acreage is not advisable.

Cherry production costs for eight Michigan orchards, 1935-1937, G. N. MORRIS (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 3, pp. 203-213, fig. 1).—Tables show the labor, power, and spray used per acre, the costs of production by items up to harvest, the cost for harvesting and marketing, overhead costs, the total production costs, and income and profits per acre and per pound. Production costs on the most profitable and the least profitable orchard and the prices received per pound for red cherries by years 1916-37 are compared.

Home-grown farm produce used by the farm household, F. M. ATCHLEY and H. A. BERG (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 3, pp. 179-183).—Tables show for 156 farms in the southern part and 70 farms in the northern part of lower Michigan, and 29 farms in the upper peninsula the average quantities and value of different farm products used by the farm households during 1937. Another table shows the average amounts used on from 51 to 284 farms in the years 1929-37. The average total values of products used in the three areas were \$289.60, \$331.63, and \$333.55, respectively, and the allowances for house rents \$213.38, \$139.63, and \$157.19, respectively. The annual value of products used during the years 1929-37 ranged from \$233.53 in 1933 to \$372.47 in 1929, averaging \$295.18. Allowances for house rent ranged from \$179.60 in 1935 to \$222.29 in 1930, averaging \$200.12.

Barriers to internal trade in farm products, G. R. TAYLOR, E. L. BURTIS, and F. V. WAUGH (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1939, pp. VI+104, figs. 2).—This is a special report to the Secretary of Agriculture by the Bureau of Agricultural Economics. The study was made in cooperation with the various State departments of agriculture, national trade associations, and other organizations. The subject is dealt with in sections on dairy products, margarine, alcoholic beverages, railroad and motor-vehicle regulation, merchant truckers, grades, standards, and labeling, quarantines, and State-financed advertising of farm products. The principal Federal and State laws and regulations and important local regulations are described, and their interference with free trade between States is discussed.

Marketing fruits and vegetables cooperatively, M. C. GAY (*Farm Credit Admin.* [U. S.], *Coop. Div., Circ. C-110* (1938), pp. IV+78, figs. 9).—The production areas, factors affecting production, distribution processes and problems, and the growth of cooperative marketing of fruits and vegetables are described. The functions of the cooperative marketing association, the essentials for success, and the organization and operation of such associations are discussed. Appendixes include the Capper-Volstead Act authorizing the association of producers of agricultural products, and proposed organization forms—organization and marketing agreements, articles of incorporation, bylaws, certificates of membership, etc.

Marketing Michigan vegetable crops, H. P. GASTON (*Michigan Sta. Circ.* 169 (1939), pp. 26, figs. 7).—This circular, which is of a popular nature, is based on detailed studies made in the Detroit markets. Most of the material was obtained by studies of actual cases, and the conclusions and recommendations are based on what at least a few growers did or are doing. The material is presented under the headings of growing what the public wants, present grading practices, grading makes selling easier and more profitable, making the pack more attractive, the package, the load, salesmanship, it pays to grow produce which will grade out well, plan production so that sales can be made when prices are high, the chain store outlet, and meeting competition.

The Wilmington market, H. S. GABRIEL (*Delaware Sta. Bul.* 214 (1938), pp. 10, 11).—Some preliminary findings are given as to preference for killed

and drawn fowls, and breeds and number of chickens and turkeys used by restaurants as shown by a survey of 197 consumers, 51 stores, and 21 restaurants.

Refrigerated food lockers: A new cooperative service, L. B. MANN (*Farm Credit Admin.* [U. S.], *Coop. Div.*, *Circ. C-107* (1938), pp. [1]+30, figs. 8).—Information as to the organization, financing, operating costs, plant layouts, and the possibilities and limitations of cooperative locker plants and associations is given. The study was limited largely to plants in the Middle West, and information was obtained chiefly from operators of private and cooperative local plants, county agents, banks, and manufacturers of equipment.

Crops and Markets, [March 1939] (*U. S. Dept. Agr., Crops and Markets*, 16 (1939), No. 3, pp. 49-68, fig. 1).—Included are reports showing the production of citrus fruits, average 1927-36, 1937, and indicated 1938; mohair and wool production, 1938; prices received by farmers by States for different products, February 15, 1938 and 1939; the prospective plantings for 1939 by States of different crops, with comparison with acreages planted 1938 and average 1929-38; and the usual market reports for cotton, dairy and poultry products, feeds, seeds, grain, and livestock and livestock products.

A graphic summary of farm animals and animal products, O. E. BAKER (*U. S. Dept. Agr., Misc. Pub.* 269 (1939), pp. 88, figs. 148).—This publication continues the series previously noted (*E. S. R.*, 80, p. 407). The maps and charts are based largely on data obtained in the Federal Census of 1930 and 1935.

RURAL SOCIOLOGY

[Investigations in rural sociology by the South Dakota Station], W. F. KUMLER. (Coop. U. S. D. A. et al.). (*South Dakota Sta. Rpt.* 1938, pp. 48-50).—The subjects discussed are a social history of the population changes, annual changes of population, and a survey of the aged.

The hop industry, a social and economic problem, P. H. LANDIS (*Econ. Geog.*, 15 (1939), No. 1, pp. 85-94, figs. 12).—The pre-war period production of hops totaled around 52 million pounds per year but decreased during prohibition to approximately 28 million pounds annually. Since repeal, production has rapidly increased to meet the domestic demand. The price received by the farmer has fluctuated almost as violently as production. The cost of growing hops varies greatly with conditions, but the average in Yakima, Wash., during the 1936-37 season was approximately 19 ct. per pound. Hops, much more than most agricultural crops, require a great deal of hand labor during the harvest, which lasts approximately 1 mo. In the Yakima Valley it has been estimated that at the peak of the harvest season 33,000 full-time workers, working 10 hr. a day 6 days a week, were required, and that from 20,000 to 30,000 workers must be drawn from great distances. During the 1935 season, the average wage earned there by men, women, and children was \$1.25 per day. Studies in 1937 showed that the average daily earnings of male heads of families were approximately \$2, while family members averaged slightly over \$1.50. The average rate per pound picked in 1935 was 1.5 ct., in 1937 it was 2 ct.

Hop pickers are acquiring the stigma of a lower class, and this cuts down the supply of local workers. The hop picking population is a very conglomerate group, including some old people, too feeble to engage in more strenuous tasks, and city dwellers chiefly out for a vacation.

Some of the larger growers must employ during the harvest season 3,000 or more workers, which means that a small town must be set up almost over night. Even in the best kept camps it is difficult to maintain sanitary conditions over a period of 3 or 4 weeks, and dysentery and typhoid are a constant threat to the workers and to the community.

The hop industry is a social liability to the community in which it is located in that it attracts a large number of people whom no community wants. The attempt to develop satisfactory market agreements is possibly a step in the right direction. Cooperation among hop growers should help the entire industry. The U. S. D. A. Farm Security Administration working with the State Department of Public Health and the California Medical Association has developed a socialized medical program for all agricultural groups that are unable to pay for medical care. In addition, the Farm Security Administration has been developing on an experimental basis transient labor camps for the migratory laborers who follow the harvest up and down the coast, where the laborers can pitch their tents on clean floors and be assured of clean streets, a pure water supply, a place to bathe, and sanitary toilet facilities. It seems unlikely that the wages of the migrants to the hop harvest will improve materially until the hop grower sees better days.

Minnesota farms and farm jobs: A manual of information for farm placement workers ([St. Paul]: Minn. State Dept. Ed., 1937, pp. [4]+98).—Production areas, types of Minnesota farms, seasonal farm work requiring additional labor, etc., are discussed.

Replacement requirements of gainful workers in agriculture in Ohio, 1930-1940, C. E. LIVELY (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul.* 109 (1938), pp. [1]+19, figs. 3).—This bulletin consists of estimates of the number of male gainful workers aged 20 yr. or over in 1930 and engaged in agriculture that will be lost to the industry through death or retirement during the decade 1930-40 for the State and for its subareas; the number of rural-farm males that will live to reach the age of 20 yr. during this decade and who, therefore, may be regarded as potential gainful workers in agriculture; and of the proportion of these potential workers that will be required for replacements.

Race consciousness as reflected in the Negro press, T. G. STANDING (Okla. A. and M. Col.). (*Southwest. Social Sci. Quart.*, 19 (1938), No. 3, pp. 269-380).—The author discusses the history, content, and function of the Negro press.

Rural youth: Their situation and prospects, B. L. MELVIN and E. N. SMITH (*Works Prog. Admin.* [U. S.], Div. Social Res., Res. Monog. 15 (1938), pp. XX+167, [pls. 24], figs. 13).—The authors show that rural youth need education and guidance as never before, and also economic, social, and recreational opportunities. "While continuation and expansion of governmental programs for youth are earnestly to be desired, the increased development of nongovernmental programs is equally as urgent."

Out-of-school rural youth in Pennsylvania, C. S. ANDERSON (*Pennsylvania Sta. Bul.* 374 (1939), pp. [2]+34, figs. 6).—This analysis of the high school and post high school records of 185 rural boys who dropped out of high school before graduation is based on data obtained for Bulletin 342 previously noted (E. S. R., 78, p. 419), information obtained from boys attending the Pennsylvania State College who were former classmates, and interviews with members of the 1933 graduating classes of the high schools included in the previous study. The characteristics of the group are analyzed and discussed, as well as the reasons for leaving school as shown by information furnished by classmates and by the principals of the schools. The study was made 9 yr. after the group entered high school and from 4½ to 8½ yr. after the boys withdrew from school. A little data is included as to girls who withdrew. Some suggestions are made as to means of meeting some of the problems of withdrawals from school.

The mean intelligence quotient of the group leaving school was 83.9 as compared with 94.2 for those completing school, and 53.1 percent of them were definitely retarded. The mean age of the out-of-school boys at the time of entering school was 15.48 yr. (as compared with 14.11 for boys who completed school), and when leaving 17.85 yr. Age retardation correlated definitely with early elimination from school and age acceleration with continuance in school. Approximately 25 percent of those who dropped out of school were reported to have been disciplinary problems. The group dropping out of school had pronounced preference for the study of agriculture and farm shop work and the least preference for academic subjects, particularly languages and mathematics. The group had a very narrow range of recreational interests, 62 percent did not participate in extracurricular high school activities and practically none in intellectual extracurricular activities, and 56 percent were not interested in any known hobby. Occupational preferences while in school had practically no relationship to later employment. About 92 percent of the boys who had dropped out of school were working in 1938, 24.3 percent being in agriculture, 22.6 percent common laborers, and 13 percent doing mechanical work. The reasons given for the withdrawal from school were employment 25.7 percent, scholastic failure 22.8, disinterest 18.9, social maladjustments 7.6, inaccessibility to schools 7.1, home and family influences 6.9, conduct and discipline 4.1, physical difficulties 3.6, past age of compulsory attendance 2.5, and miscellaneous 1 percent.

Human and physical resources of Tennessee.—XXVII, Education: Public and private. XXVIII, Illiteracy, reading habits, libraries, C. E. ALBRED, S. W. ATKINS, and F. M. FITZGERALD (*Tenn. Agr. Col., Agr. Econ. and Rural Sociol. Dept. Monog. 81 (1938), pp. [I]+VII+ 418-460, figs. 11*).—Continuing this series of monographs (E. S. R., 80, p. 416), a study is reported of public and private education, the prevalence of illiteracy, reading habits, and libraries.

"Tennessee is handicapped in providing educational opportunities since she has only a small number of adults in proportion to children of school age, relatively low per capita income and per capita wealth. . . . Rural elementary schools are the most poorly equipped of any class of public schools in the State, their average value ranging in 1930 from the \$17 per pupil in Hancock County to \$122 in Shelby County. The value of school property per pupil enrolled in colored schools was less than one-half that for whites, or \$45 and \$96, respectively. The number of consolidated schools in Tennessee has increased rather rapidly during recent years due to the combination of many of our smaller rural schools.

"Approximately 7.2 percent of the total population in Tennessee in 1930 could not read or write. This was a decrease of 32 percent since 1880. Males had a higher percentage of illiteracy than females, with 8.4 percent and 6 percent, respectively. However, the proportion of illiterates among Negroes is nearly 3 times that of native whites. A higher rate of illiteracy is found among people 21 yr. of age and over since educational opportunities were not so prevalent formerly as at present. The rural population in Tennessee in 1930 had 8.8 percent illiteracy which was twice that of the urban population. Areas in the State relatively low in total illiteracy are those with either a low ratio of Negro population or a high per capita wealth, or both.

"Tennessee and the South rank low in the extent to which the people read. In 1931 Tennessee ranked fortieth, with an average of 122 magazines circulated per 100 families. . . . In 1932 Tennessee had 48 public libraries containing 650,765 books, exclusive of governmental publications. These libraries are located in 48 towns and cities in 42 counties. Most of the city residents in this

State have access to public libraries but only a small percentage of the rural residents have this advantage."

Recreational development of the Southern Highlands Region: A study of the use and control of scenic and recreational resources ([*Knorrville*]: *Tenn. Valley Authority* [U. S.], *Dept. Regional Planning Studies*, 1938, pp. XIII+61, [pls. 21, fig. 1]).—The Southern Highlands Region, it is stated, includes an area of 44,400 sq. miles in 106 counties of 7 States possessing scenic and recreational resources of such quality as to make it potentially one of the major recreational regions of the United States.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Agricultural education programs (*U. S. Dept. Int., Off. Ed. Monog.* 19 (1938), pp. V+21).—This monograph makes suggestions for the further development of vocational education in agriculture under the National Vocational Education Acts. It incorporates the results of the discussions and conferences of a committee appointed by the American Vocational Association.

A basis for the improvement of education in rural Monroe County, Indiana, H. L. SMITH and F. R. NOFFSINGER (*Ind. Univ., School Ed. Bul.*, 12 (1936), No. 2, pp. 165, figs. 37).—This bulletin contains the findings in a survey made in 1934 by the School of Education, Indiana University, in cooperation with the U. S. Civil Works Administration. Monroe County and the development of education in it are described. The data as to teachers, school districts, and buildings, administrative organization of the schools, daily programs, age, grade placement, intelligence, and progress and achievement of children are analyzed and discussed. The adjustment of the school to pupils is also discussed, and suggestions are made for the improvement of educational conditions in the county.

Agricultural education for adolescents in Pennsylvania, H. G. BUCHER (*Diss., Temple Univ., Philadelphia*, 1937, pp. 198, figs. 9).—This is a dissertation presented to Teachers' College of Temple University. The several chapters deal with the status of agriculture, development of agricultural education, legal provisions relating to agricultural education, agricultural education in relation to school costs and school attendance, need for reorganization of agricultural education, determinants for agricultural education, and summary and conclusions. An appendix (pp. 171-192) deals with significant considerations related to the reorganization of agricultural education, and another includes the author's specific recommendations as to school administration and organization, instruction, pupil activities, and general policy (pp. 193-198).

Homemaking education program for adults, M. S. LYLE and R. VAN HORN (*U. S. Dept. Int., Off. Ed., Vocat. Ed. Bul.* 195 (1938), pp. VI+125, fig. 1).—The practices and procedures for organizing and conducting adult programs in homemaking are discussed. Illustrations are given from local communities and States in chapters dealing with the place of such education in the adult education movement; types of State, city, and small-town programs; the preparing of teachers and leaders; procedures for classes; and illustrations of material on organization, programs, lessons, etc.

An exploratory study of the teaching of botany in the colleges and universities of the United States, E. L. STOVER ET AL. ([*Ithaca, N. Y.*]: *Bot. Soc. Amer.*, 1938, pp. [2]+46).—This is the report of a committee on the teaching of botany in colleges and universities appointed by the Botanical Society of America in 1936. It considers certain general features of a questionnaire study and the objectives, content, procedure, and methods of the study, and

an evaluation of student achievement. Lists of supplementary readings are appended.

Teaching the control of loose smuts of wheat and barley in vocational agriculture classes, W. A. ROSS and R. J. HASKELL (Coop. U. S. D. A.). (*U. S. Dept. Int., Off. Ed., Vocat. Div. Leaflet 3, rev. (1938), pp. IV+11, figs. 4.*)—This leaflet includes illustrative material, an analysis of operative training content for the job of treating seed, information in connection with instruction as to seed treatment, and a suggested teaching plan.

4-H club insect manual, M. P. JONES (*U. S. Dept. Agr, Misc. Pub. 318 (1939), pp. 63, figs. 133.*)—This manual is planned on the basis of 1 to 3 years' work in 4-H clubs, the first on the identification of insects, the second a study of life histories and control, and a third on demonstrations, exhibits, and surveys. A monthly calendar of club activities is outlined for each year.

Animal pathology and hygiene, R. GRAHAM and J. SAMPSON (*Springfield: Ill. State Dept. Agr., [1938], pp. 133, [pl. 1], [figs. 67].*)—The cause and methods of prevention and control of common diseases of animals are discussed in 60 lessons for vocational students in agriculture.

Introduction to agricultural economics, F. R. YODER (*New York: Thomas Y. Crowell Co., [1938], 3. ed., pp. XIX+494, figs. 10.*)—This is the third printing of the textbook previously noted (E. S. R., 62, p. 187). Appendixes have been added including statistical tables and a brief description of the agricultural policies of the United States 1927-38.

Farm management: Problems in analyzing, interpreting, and adjusting, L. A. BRADFORD and R. H. WOODS, edited by R. W. GREGORY (*Chicago: J. B. Lippincott Co., [1938], pp. VII+216, [figs. 2].*)—This set of problems, references, forms, etc., is designed for use in day school and part-time classes in vocational agriculture, with a view to making the teaching of the problems and principles basic to proper farm organization and management more objective.

A guide to the literature of rural life, compiled by B. Y. LANDIS (*New York: Amer. Country Life Assoc., 1939, 4. ed., rev., pp. 15.*)—Approximately 500 titles of representative books and pamphlets are listed, grouped by subject (E. S. R., 63, p. 558).

Subject matter in money management in junior high school home economics, L. B. MAGEE (*Diss. Columbia Univ., New York, 1937, pp. 137.*)—This Ph. D. dissertation discusses the subject matter in money management as taught in classes in home economics in junior high schools, the duplication of such courses in the fields of home economics and social science, and the extent to which the needs of pupils are being met.

Workers in subjects pertaining to agriculture in land-grant colleges and experiment stations, 1938-39, M. A. AGNEW (*U. S. Dept. Agr., Misc. Pub. 335 (1939), pp. I+184.*)—This is the usual annual list (E. S. R., 79, p. 273) showing the workers in agriculture and home economics, the personnel of the Office of Experiment Stations, and the officers and standing committees of the Association of Land-grant Colleges and Universities.

FOODS—HUMAN NUTRITION

[Foods and nutrition studies by the Florida Station] (*Florida Sta. Rpt. 1938, pp. 76, 87-89, 127.*)—In this annual report summaries, some of which cover an extension of work noted previously (E. S. R., 79, p. 560), are given by R. B. French on the vitamin C content of miscellaneous fruits and vegetables and the effect of home cooking in different ways and with different types of utensils on the vitamin C content of cabbage and cauliflower; by O. D. Abbott, R. Over-

street, and C. F. Ahmann on the nutritive status of children and women in Citrus County, and on the chemical composition and nutritive value of several Florida honeys; by Abbott on the vitamin C content of tomatoes as affected by various factors; and by W. B. Tisdale and R. K. Voorhees on microbiological analyses of orange juice.

[Studies in foods and nutrition of the Washington Station] (*Washington Sta. Bul.* 368 (1938), pp. 45-47).—Included in this progress report (E. S. R., 79, p. 417) are summaries of studies by E. N. Todhunter and R. C. Robbins on the vitamin C content of Winter Banana apples of two harvesting periods, apples of the White Winter Pearmain and Stayman Winesap varieties, and frozen-pack peas, on the distribution of vitamin C in different parts of the Winter Banana apples, and on the vitamin C requirements of college women; by Todhunter on the vitamin C content of frozen red raspberries of the Cuthbert and Antwerp varieties; and of a continuation of the investigation by M. M. Boggs of factors influencing the cooking quality of peas preserved by the frozen-pack process.

Variations in sampling beef and pork roasts for press-fluid investigations, A. M. CHILD and E. Z. MOYER. (Minn. Expt. Sta.). (*Food Res.*, 3 (1938), No. 5, pp. 505-512, fig. 1).—In continuation of previous studies (E. S. R., 74, p. 874) the authors determined the content of press fluid, which consists of moisture, soluble material, and the colloidal fraction pressed from muscle by the pressometer. The results were statistically analyzed to find the degree of variation between samples from comparable slices within a roast, from successive slices proceeding from the center of a roast of beef and pork, and from different cuts of pork. The semitendinosus beef muscle was roasted to an internal temperature of 58° C. at 125° and the longissimus dorsi of pork muscle to 84° at 150°. No significant difference was found in the quantities of press fluid from comparable slices of beef and pork taken at equal distances from each side of the center of the roast, nor between halves of roasts. In the beef roasts the press fluid content decreased progressively from the center to the ends of the roasts, but no such gradient occurred in the pork roasts. Press fluid percentages from the loin end and shoulder cuts of pork were not significantly different, but both cuts contained amounts which were significantly lower than the center cut. The coefficient of correlation between press fluid and total cooking losses did not vary significantly from 0 in the beef roasts, but the pork roasts showed a significant negative correlation.

Effect of coagulation on press fluid, shear force, muscle-cell diameter, and composition of beef muscle, M. J. SATORIUS and A. M. CHILD. (Minn. Expt. Sta.). (*Food Res.*, 3 (1938), No. 6, pp. 619-626).—In continuation of previous studies (E. S. R., 80, p. 557), the authors investigated the effect of coagulation of muscle on shear force (tenderness), diameter of muscle fibers, total moisture, and ether extract, and of different degrees of coagulation or different internal temperatures of muscle on press fluid, total moisture, total losses, shear force, and diameter of muscle fibers, using the triceps brachii, adductor, and longissimus dorsi muscles of beef. While the tenderness of the triceps brachii and adductor muscles was not affected, coagulation to 58° C. made the longissimus dorsi muscles more tender. The diameter of muscle cells was decreased from 12 to 16 percent, the ether extractable material was increased about 35 to 40 percent, and the total moisture was decreased about 4 percent of the original amount during coagulation to 58°. The press fluid and total moisture were not affected when the internal temperature was increased between 58° and 67°, but both were decreased as the internal temperature was changed from 67° to 75° with total losses increasing with each

increment in internal temperature. Coagulation up to 67° progressively decreased the diameter of the muscle fibers and increased the tenderness. Between 67° and 75° the fiber diameter remained unchanged and the tenderness decreased.

Problems in meat research.—I, Four comparable cuts from one animal. II, Reliability of judges' scores, M. J. SATORIUS and A. M. CHILD. (Minn. Expt. Sta.). (*Food Res.*, 3 (1938), No. 6, pp. 627-635).—In continuation of the study noted above, the authors report that four comparable roasts homogeneous in physical properties may be obtained from one animal of pork or beef and that the rib and loin ends, weighing about 2 lb. each, from the center pork loin are comparable, as are the seventh-to-eighth and ninth-to-tenth ribs, weighing 7 and 6 lb., respectively, from beef. The small difference in cooking losses need not be considered if the cuts are rotated in an experiment. Using the grading sheet recommended by the cooking committee of the Cooperative Meat Investigations, a panel of five judges found an interdependence existing between flavor and aroma, quantity and quality of juice, flavor-aroma and juiciness, texture and tenderness, flavor-aroma and tenderness, and tenderness and juiciness. No correlation could be demonstrated where mechanical tests were involved between press fluid and shear stress, and press fluid and flavor-aroma. A high correlation existed between the grading-sheet scores for tenderness and the mechanical shear test, with no correlation between quantity of juice as judged by grading and press fluid content. Other factors, such as flavor-aroma, appear to be more important in affecting juiciness than the content of ether-extractable material.

A study of rate of decomposition of haddock muscle at various temperatures as indicated by ammonia content, G. C. CROOKS and W. S. RITCHIE. (Mass. Expt. Sta.). (*Food Res.*, 3 (1938), No. 6, pp. 589-598, figs. 3).—The ammonia produced in fresh and frozen ground haddock muscle kept under different storage conditions was determined as a means of measuring the rate of protein decomposition. A correlation was demonstrated between the amount of ammonia present and the state of preservation as determined organoleptically. With an ammonia content not over 35 mg. per 100 gm. of muscle the fish was sound and of good quality, but when the content reached 60 mg. there was a stale or "fishy" odor which became putrefactive as the ammonia content increased to from 75 to 100 mg. per 100 gm. In fresh ground haddock fillets stored at from 4° to 5° C. for 9 days the ammonia content increased less than 1 mg. per 100 gm., as compared to 153 mg. for samples stored for 9 days at from 9° to 10° and 318 mg. for those stored for 7 days at from 24° to 25°. The ammonia content of frozen fillets did not change appreciably during 28 days of storage, but within 9 days after defrosting the content was 73.1 mg. as compared to 8.5 mg. at the time of defrosting, and after 21 days had reached 183.7 mg. of ammonia per 100 gm. of muscle.

Chemical studies on canned meats [trans. title], Y. OKUDA (*Bul. Sci. Fakult. Terkult., Kjuû Imp. Univ., Fukuoka, Japan.*, 8 (1938), No. 1, pp. 16-30, figs. 4; *Eng. abs.*, pp. 27-30).—The results of previous investigations on chemical changes of muscle protein in canning, the contents of gases and metals in stored cans, and the carbon dioxide and hydrogen gases produced at canning and in storage are summarized. The results of recent studies on the protein, fat, and nutritive value of stored canned meats indicated that (1) proteins from fresh and from canned beef aged for 2 to 15 yr. contained nearly equal amounts of nitrogen but differed widely in ash content, the ash tending to increase with increased length of storage; (2) only slight differences occurred in the analyses of the proteins by the Van Slyke method; (3) no consistent changes

occurred in the composition of the fat during storage except that the total acid value tended to increase with increased length of storage; (4) all fats gave a negative test for vitamin A potency (Carr-Price test); and (5) the nutritive value of canned beef from 2 to 15 yr. of age and of canned crab from 1 to 5 yr. of age showed only slight differences in feeding experiments with albino rats.

A note on yeast obtained from slimy sausage, E. M. MEAK and L. BONAR. (Univ. Calif.). (*Food Res.*, 3 (1938), No. 6, pp. 615-618).—The authors report the isolation of *Debaryomyces* yeasts from fresh sausage which closely resembled cultures of *D. guilliermondii nova zeelandicus* Lodder.

Home-preparation of fruits and vegetables for the freezer-locker, H. CARLTON (*Tennessee Sta. Bul.* 168 (1939), pp. 11).—Information secured during an extensive survey of the frozen fruit and vegetable industry and freezer-locker installations throughout the country has been assembled for the benefit of those who are desirous of preserving home-grown fruits and vegetables in frozen storage. Suggestions are given for the proper temperatures for freezing and storage, the selection of containers, general preparation of the materials to be frozen, with special directions for fruits and for vegetables, and care in cooking and serving of the frozen foods in the home.

Types of bacteria surviving in frozen-pack vegetables, A. G. LOCHHEAD and A. H. JONES (*Food Res.*, 3 (1938), No. 3, pp. 299-306).—In confirmation of the findings noted in a preliminary report (E. S. R., 76, p. 878), species of *Micrococcus* and *Flavobacterium* were found to be relatively more resistant to freezing than the other types of bacteria present in frozen vegetables. Bacterial counts made on vegetables when freshly packed and after 8 mo. of freezing showed that the plates incubated at 37° C. for 2 days had reductions of from 58.6 to 93.5 percent as compared with 80.8 to 94.1 for those incubated at 20° for 4 days, and 95.8 to 99.9 percent for those incubated at 4° for 21 days. In vegetables frozen for 4 mo. the micrococci increased in numbers as the incubation temperature was increased from 4° to 37°.

The effect of Federal and State regulations on the utilization of corn products, W. G. CAMPBELL. (Coop. U. S. D. A.). (*Contrib. Iowa Corn Res. Inst. [Iowa Sta.]*, 1 (1939), No. 2, pp. 257, 258).—This is a brief discussion of the terms of the Food and Drug Act applicable to corn products. As an illustration it is noted that the packing of field corn and its sale under a label designating it either as "canned corn" or "canned sweet corn" constitutes an adulteration within the meaning of the law as well as a misbranding.

A quick method of predetermining the culinary quality of potatoes, with special reference to color, E. J. WHEELER (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 3, pp. 213-215, fig. 1).—Plugs were extracted from test tubers with a $\frac{3}{8}$ -in. \times 6-in. brass cylinder thrust through the stem and seed ends and middles of the potatoes, and 0.5-in. pieces cut from the ends of each plug were placed in small glass tubes containing 95 percent ethyl alcohol for 1 hr. and then examined for color and shrinkage. Tubers whose plugs or sections remained white and firm in the alcohol cooked white, while those having shrunken and discolored plugs were usually gray or dark colored when boiled. Color, texture, and flavor were correlated closely. Potatoes that cooked white were usually mealy in texture and of good flavor, while those that discolored were often soggy and of poor flavor. This method of testing for quality compared very favorably with cooking tests.

Available carbohydrate and acid-base balance in pulses, K. P. BASU, S. P. BOSE, M. A. QUADER, and H. N. DE (*Indian Jour. Med. Res.*, 26 (1939), No. 3, pp. 637-644).—The available carbohydrate in eight varieties of pulses common

in Indian diets was determined by chemical methods to be about 99 percent in *Lathyrus sativus*; 95 in *Phaseolus mungo*, lentil, and *Cajanus indicus*; 92 in *Pisum sativum*; 87 in *Cicer arietinum* and soybean; and about 84 percent in *Phaseolus mungo* var. Linn. From analysis of the ash constituents the potential acidities varied from 1.87 approximate titratable acidity per 100 gm. for *P. mungo* to 5.01 for lentil.

Dry milk solids for cake baking, O. E. STAMBERG and C. H. BAILEY. (Univ. Minn.). (*Bakers Tech. Digest*, 13 (1938), No. 6, pp. 103, 104, 107).—The results of laboratory tests using roller- and spray-process dry milk solids in commercial cake batters are reviewed. The minimum variation in quality of the cake resulted when the dry milk solids were reconstituted in water in the amount of 1 lb. of solids to 1 gal. of water. The method of adding the dry milk solids in the creaming stage was the most satisfactory, while the method of sifting the dry milk solids with the flour was the least satisfactory for loaf and layer cakes. Loaf, sponge, and yellow and white layer cakes of excellent quality were produced when the amount of dry milk solids was 30 percent, based on the flour content, with a concomitant increase in water to maintain a constant viscosity in the batter, and a slight increase in the percentage of baking powder. Two independent groups of judges ranked yellow layer cakes made with 15 percent dry milk solids slightly above those made with fresh skim milk, while those made with 8 percent and 30 percent dry milk solids ranked the lowest. Cakes containing butter up to 50 percent of the shortening scored higher than those made with hydrogenated shortening and were decidedly superior in flavor. It was observed that higher percentages of dry milk solids gave greater stability to cakes and permitted a more favorable formula for the use of butter as part of the shortening.

Altitude vs. baking powder using tentative A. A. C. C. cake formula, M. A. BARMORE (*Cereal Chem.*, 16 (1939), No. 1, pp. 145-147, figs. 2).—In a series of cakes made by a modification of the A. A. C. C. formula with cake flour and fresh egg albumen and baked at altitudes ranging from sea level to 10,000 ft., the best products were obtained when the amount of cream of tartar was calculated from the equation $y = -0.03A^2 - 0.25A + 6$, where y equals the cream of tartar in grams and A the altitude in thousands of feet. The addition of 30 gm. of sugar to the formula gave an excellent cake when baked at sea level, but at an altitude of 10,000 ft. the cake fell flat, indicating that the sugar tolerance differs for the same flour at different altitudes.

Salmonella food poisoning: Infection or intoxication? G. M. DACK and E. DAVENSON (*Food Res.*, 3 (1938), No. 3, pp. 347-349).—From a review of the literature, the authors present evidence in favor of infection as the cause of *Salmonella* food poisoning.

The application of isotopic indicators in biological research, G. HEVESY (*Enzymologia*, 5 (1938), No. 3, pp. 133-157).—The use of isotopic indicators in determinations of the rate, place, and sequence of formation of the organic constituents of the body is discussed in this paper.

The use of deuterium in biological work, A. KROGH (*Enzymologia*, 5 (1938), No. 3, pp. 185-189).—The application of deuterium (heavy water) for the study of exchange problems between organic substances and water and for the labeling of organic molecules is discussed in this paper.

[Nutrition studies of the South Dakota Station] (*South Dakota Sta. Rpt.* 1938, pp. 33, 34).—Progress is reported on attempts to determine the distribution of flavin and the antipellagra factor in different organs and tissues of lamb, by E. Pierson.

Digestibility and nutritional value of cereal proteins in the human subject, J. R. MURLIN and H. A. MATTILL (*Jour. Nutr.*, 16 (1938), No. 1, pp. 15-35).—An experimental procedure is described by the authors, with the assistance of J. S. Carman and E. M. Austin, for determining the milk replacement value of cereal proteins. The method was studied with six adult subjects receiving a diet in which 80 percent of the nitrogen was from milk, 10 percent from cream, and 10 percent from fruit for a 3-day period, followed by a 4-day period in which the milk was replaced with cereal. The replacement value averaged 93 for wheat endosperm, 89 for precooked rolled oats, and 83 for whole wheat cereal. The biological values of the three cereals, calculated by the Mitchell method (E. S. R., 51, p. 407), averaged 83, 89, and 85, respectively. The apparent digestibility, calculated from the percentage which the cereal nitrogen of the feces is of the amount consumed, averaged 78 percent for the wheat endosperm, 61 for the whole wheat, and 60 percent for the precooked oats. The true digestibility, which does not include the alimentary or endogenous fecal nitrogens, averaged 99, 86, and 85 percent, respectively, for the three cereals.

The egg-replacement value of several proteins in human nutrition, E. E. SUMNER, H. B. PIERCE, and J. R. MURLIN (*Jour. Nutr.*, 16 (1938), No. 1, pp. 37-56).—Following the method used in the study noted above, the ability of various foods to replace the nitrogen of fresh whole egg was tested with 10 adult subjects. The basal diet consisted of cornstarch, sucrose, lactose, canned fruits, and vitamin B concentrate tablets, and supplied from 0.4 to 0.6 gm. of nitrogen a day. The experiment lasted 40 days and was divided into 10 periods during which 6.5 gm. of nitrogen were furnished by powdered whole and fresh milk, with and without yeast, wheat endosperm, and egg alone and with yeast. The apparent coefficients of digestibility averaged 80 percent for powdered whole milk, 77 for fresh milk, 73 for fresh milk and yeast, 69 for whole milk and yeast, 70 and 70 for egg and yeast in two periods, respectively, and 77 and 80 for wheat endosperm in two periods, respectively, as compared to 76 and 81 percent for egg protein in two periods. The estimated true coefficients of digestibility averaged 99, 98, 96, 93, 93 and 94, and 95 and 96 percent, respectively, for the different proteins as compared with 97 and 98 percent for egg protein in two periods, respectively.

The biological value of milk and egg protein in young and mature rats, E. E. SUMNER (*Jour. Nutr.*, 16 (1938), No. 2, pp. 129-139).—In continuation of the study noted above, using the paired feeding technic of Mitchell and Beadles (E. S. R., 63, p. 393) and the nitrogen "balance sheet" method on 40- to 50-day-old and 1-year-old rats, the authors determined the biological value of dried whole egg protein and of dried milk. At the 8-percent level of feeding the average biological value of egg was 97 and of milk protein 84 for the young rats and 85 and 64, respectively, for the mature rats. At the 5-percent level the egg had a biological value of 94 and the milk of 78 for the mature rats. The coefficients of digestibility in the mature rats were 78 and 92, respectively, for the apparent and true digestibility of the egg and 79 and 95, respectively, for the milk. It is concluded that more protein of good quality is required for growth in young rats than for maintenance in mature rats.

The biological value of milk and egg protein in human subjects, E. E. SUMNER and J. R. MURLIN (*Jour. Nutr.*, 16 (1938), No. 2, pp. 141-152).—In continuation of the study noted above, the authors determined the biological value of dried whole egg flake and of whole milk powder in the diets of four adult men. The basal diet included all foods except eggs and milk and supplied about 3 percent of the calories from protein, 24-29 from fat, and 68-72 from car-

bohydrate. The addition of egg or milk brought the nitrogen intakes up to from 3.5 to 5.4 gm. per day. Urine and feces collections were made over a 7-day period following 1 preliminary day on the test diet, and the total nitrogen excreted during the last 2 or 3 days was used in calculating the biological value of the supplements.

The average biological value obtained for egg flake was 65 and for milk powder 62. The coefficients of digestibility were 80 and 92, respectively, for the apparent and true digestibility of the egg and 76 and 90, respectively, for the milk, indicating a slight superiority of the egg over the milk protein.

The egg-replacement value of the proteins of cereal breakfast foods, with a consideration of heat injury, J. R. MURLIN, E. S. NASSET, and M. E. MARSH (*Jour. Nutr.*, 16 (1938), No. 3, pp. 249-269).—In continuation of the study noted above, the authors compared the nutritive value of the proteins of seven cereal breakfast foods with egg protein, which is assumed to have a biological value of 100, in a 1-week test on 10 adult men. The basal diet supplied 5 percent of the calories in the form of protein, 44 percent in carbohydrate, and 51 percent in fat, and contained adequate vitamin supplements. The egg or cereal proteins, which were fed during alternate 5-day periods, supplied 78 percent of the total nitrogen intake, the dairy products 11 percent, and fruit and other foods 11 percent.

Representing the extent to which the cereal proteins absorbed replaced egg protein, precooked whole grain oats had an average replacement value of 87, wheat endosperm 72, granulated wheat containing the germ 70, torn wheat 68, toasted "whole" wheat 64, flaked wheat 63, and inflated wheat 57. Whole grain oats also had the highest biological value, a measurement which does not take account of differences in alimentary waste from the body, followed in order by torn wheat, toasted whole wheat, granulated wheat with germ, flaked and inflated wheat cereals, and wheat endosperm. The lower rank of the flaked and inflated whole wheat cereals is believed to be due to the high heat to which they are subjected in the manufacturing process.

Effect of gelatine on muscular fatigue, G. B. RAY, J. R. JOHNSON, and M. M. TAYLOR (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 2, pp. 157-161, fig. 1).—The daily administration for about 50 days of 60 gm. of gelatin, containing about 15 gm. of glycine and mixed with 8 oz. of orange and lemon juices, to six men exercising on an ergometer increased the work output before fatigue set in from 37 to 240 percent above the level when the subjects were given the same diet without gelatin for about 25 days. During a recovery period of about 35 days when the gelatin was discontinued and the fruit juices alone were given, the work output rapidly fell to about the pregelatin level. Similar tests with four women receiving 45 or 67.5 gm. of gelatin a day produced no appreciable effect on work output.

The iron, copper, and manganese contents of some Philippine foods, F. G. GONZALEZ and A. I. DE LEON. (Univ. Philippines). (*Univ. Philippines, Nat. and Appl. Sci. Bul.*, 6 (1938), No. 2-3, pp. 177-185).—In 38 common Philippine fruits and vegetables, the iron content, determined by the thiocyanate method, varied from 0.0645 to 0.7353 percent on the dry basis; the copper content, by the chloroform-pyridine method, from 0.00328 to 0.0028 percent; and the manganese content, by a modification of the periodate method (E. S. R., 66, p. 806), varied from 0.0014 to 0.01268 percent. The green leafy vegetables were richest in the three minerals, followed in order by the vine fruits, roots and tubers, and the tree fruits, as sources of iron and manganese. In copper content the tree fruits ranked ahead of the roots and tubers.

The availability of calcium in spinach, in skim milk powder, and in calcium ovalate, B. W. FAIRBANKS and H. H. MITCHELL. (Univ. Ill.). (*Jour. Nutr.*, 16 (1938), No. 1, pp. 79-89).—In bio-assays conducted by the paired-feeding method the availability of the calcium of fresh, home-cooked, and canned spinach was compared with that of the calcium of skim milk powder. For each 100 mg. of calcium stored by the rats on the milk-supplemented diet 45 mg. were stored on the fresh spinach diet, 44.5 mg. on the cooked spinach diet, and 48 mg. on the canned spinach diet. The milk calcium also promoted a greater rate of skeletal growth as judged by the increase in body lengths of three pairs of rats on each test food. The average retentions of calcium in 10 days were 288 mg. when the diet was supplemented by calcium gluconate and only 82 mg. when calcium oxalate was fed. It is concluded that calcium oxalate is not utilized by the growing rat.

Utilization of calcium of spinach and kale, M. L. FINCKE and E. A. GARRISON. (Oreg. State Col.). (*Food. Res.*, 3 (1938), No. 6, pp. 575-581).—Calcium balance experiments were made on two healthy women on diets in which 84.7 percent of the total calcium content of 0.4 gm. in test diet 1 was supplied by kale, 79.9 percent of the total 0.304 gm. of calcium in diet 2 by spinach, and 86.9 percent of the total 0.445 gm. of calcium in diet 3 by spinach. Vitamin B₁ hydrochloride to provide about 300 Sherman units per day was added to diet 1. The other constituents of the diets were soda crackers, butter, sugar, ground lean beef, bacon, tomato juice, weak tea infusion, and sodium chloride, and in diets 1 and 2 cored and pared apple. The daily calcium balances averaged -0.026 and -0.049 gm., respectively, for the two subjects on diet 1 containing kale as compared to -0.096 and -0.131 gm. on diet 2, and -0.149 and -0.164 gm. on diet 3 containing spinach as the chief source of calcium, indicating that the calcium of the kale was considerably better utilized than that of the spinach.

Electrolyte excretion studies in rats maintained on low-Na and low-K diets, E. ANDERSON and M. JOSEPH. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 3, pp. 344-347).—The metabolism of sodium and potassium was studied by means of radioactive atoms in groups of rats maintained on the low sodium and low potassium diets of McCollum. The rats receiving the low sodium diet excreted 55.2 percent of the radioactive sodium and 7.1 percent of the radioactive potassium within 48 hr. as compared to excretions of 43.8 and 9.5 percent, respectively, by rats receiving the standard ration. The administration of cortin to the sodium-deficient rats reduced the sodium excretion to 49.9 percent and increased the potassium excretion to 14.4 percent. The rats maintained on the low potassium diet excreted 46.7 percent of the radioactive sodium and 6.3 percent of the radioactive potassium within 48 hr. as compared to excretions of 43.8 and 9.5 percent, respectively, by the rats receiving the standard ration.

Urinary excretion of radioactive Na and K in adrenalectomized rats, with and without salt, E. ANDERSON and M. JOSEPH. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 3, pp. 347-350).—In continuation of the study noted above, the authors report that adrenalectomized rats excreted 60 percent of the administered radioactive Na and 5 percent of the radioactive K within 48 hr. as compared to excretions of 43.8 and 9.5 percent, respectively, by normal rats. The addition of 1 percent of NaCl to the drinking water of the test rats reduced the Na excretion to 45 percent and increased the K excretion to 10.7 percent, indicating that the NaCl enabled the adrenalectomized rats to metabolize Na and K normally.

A study of food consumption in the city of San Juan [trans. title], S. L. DESCARTES and S. DÍAZ PACHECO (*Puerto Rico Col. Sta. Circ. 107 (1938), Span. ed., pp. 51, figs. 19*).—The consumption of 29 different foods by 16,189 persons in 2,645 families, representing 11 percent of the total population of San Juan, was determined by a survey made in the summer of 1937. The families were grouped according to income into five classes with mean incomes of about \$374, \$838, \$1,609, \$2,794, and \$5,182 per year, respectively. The average family group, including servants, contained 6.1 persons. The per capita annual consumption of the various foods is reported as follows: Rice, 132 lb.; beans, 42; potatoes, 71; sugar, 57; coffee, 11.7; bread, 43; soupbone, 30; beef, 26; pork, 10.7; hens and chickens, 18.5; fresh fish, 9.6; codfish, 9.4 lb.; milk, 91 qt.; evaporated milk, 12.2 lb.; condensed milk, 1.3; butter, 5; and butter substitutes, 1.2; cheese, 2.7 lb.; eggs, 13.6 doz.; tomato sauce, 12.2 lb.; sweetpotatoes, 16; dasheen, 27; yams, 7.7; cassava, 0.6; fresh tomatoes, 22; cabbage, 6.2; peppers, 9.9 lb.; lettuce, 20.3 heads; plantains, 109; and bananas, 129. As the income increased the consumption of milk and other dairy products, meat and chicken, bread, potatoes, sugar, and tomato sauce also increased, while the consumption of rice, codfish, and oleomargarine decreased.

Comparison of food intakes for weekdays and for Saturday and Sunday, R. M. LEVERTON and A. G. MARSH. (Nebr. Expt. Sta.). (*Jour. Home Econ.*, 31 (1939), No. 2, pp. 111-114).—From the data on nitrogen and calcium intakes collected in 24 balance studies made on girls between the ages of 17 and 24 yr., a significant variation in food intake for weekdays and for week ends is indicated. Fifteen girls served as subjects in studies of 1 week's duration and 8 were subjects for a 10-day period. The percentage differences between the intake for the 5-weekday period and the 3-weekday plus Saturday and Sunday period ranged from 0.6 to 48.5 and averaged 15.9 percent for the nitrogen intake and from 1.1 to 24.1 and averaged 12.7 percent for the calcium intake, and between the 5-weekday period and the Saturday and Sunday period the differences were from 2.3 to 28.8 with an average of 12.5 percent and from 2.7 to 55.2 with an average of 19.6 percent, respectively. Between the 5-weekday period and the calendar-week period the differences were from 0.7 to 16.7 and averaged 6.1 percent for nitrogen intake and from 1.7 to 19.1 and averaged 7.3 percent for calcium intake, and between the calendar-week period and the 10-day period the differences were from 0.4 to 16.6 and averaged 6.5 percent and from 1.4 to 11.2 and averaged 5.5 percent, respectively. The authors stress the need of considering no less than a calendar week as the shortest time unit for studies of food consumption or metabolism.

Summer diets of the poor in Washington, D. C., D. G. WIEHL and C. E. PALMER (*Milbank Mem. Fund Quart.*, 17 (1939), No. 1, pp. 5-28, figs. 3).—A survey was made by the U. S. Public Health Service with the cooperation of the Milbank Memorial Fund of the food eaten during a 2-day summer period by 602 white and Negro families receiving funds from the Public Assistance Department or having a Works Progress Administration employee or an employed worker. The families were classified into five income groups, ranging from those having less than \$2.67 to those having \$6.67 or more, using a class interval of \$1.33, per food cost unit per week. In analysis of the data, the methods for calculating cost of food and adequacy of diets developed by the U. S. D. A. Bureau of Home Economics were employed.

In the highest income group, the diet of the average white family was adequate in calcium and iron and exceeded the standard allowance for calories and protein, while the Negro diet furnished an excess of calories, protein, and iron, but less than the adequate allowance for calcium. The average diet

of the families in the three median income groups, between \$2.67 and \$6.66 weekly income per cost unit, furnished between minimum and adequate amounts of calories, protein, and iron, and of calcium in all but two groups of white families and in only three groups of Negro families. The average diet of the white families receiving less than \$2.67 a week per cost unit was below the estimated standard allowance for calories and between minimum and adequate for protein, calcium, and iron, while that of the Negro families exceeded the standard allowance for calories, equaled or exceeded the adequate allowance for protein, and was between minimum and adequate in iron and below the minimum requirement for calcium.

Calorie requirements of south Indian children, B. G. KRISHNAN (*Indian Jour. Med. Res.*, 26 (1939), No. 3, pp. 631-636).—The daily caloric intake of 107 boys calculated on the edible portion of raw food eaten during a 7-day period was 870 per capita for 2- and 3-year-old boys, 1,140 for 4- and 5-year-old, 1,300 for 6- and 7-year-old, 1,600 for 8- and 9-year-old, and 1,760 calories for 10- and 11-year-old boys. Compared with the standard widely used in nutrition work in India, the calculated intakes differed by +11, +10, 0, +3, and -3 percent, respectively, for the 5 age groups.

Some body measurements of Texas school children, J. WHITTAKER (*Texas Sta. Bul.* 567 (1939), pp. 61, figs. 24).—This report presents comparisons of the size, body build, and average rates of growth of school children from San Antonio public schools serving as subjects in the extensive investigation, other phases of which have been noted previously (*E. S. R.*, 74, p. 877). Over 7,300 measurements each of weight, and standing and sitting height, and about 3,000 each of shoulder and hip width were made upon 928 white children from 7 to 13 yr. of age, 790 Mexicans from 8 to 15 yr., and 725 Negroes from 7 to 17 yr. of age. The collection of data covered a period of 2.5 school years, during which the pupils were weighed once each month and measured for height once each semester and for width of hips and shoulders once or twice during the entire period.

For all races the rate of growth in weight was the most rapid, followed in general in decreasing order by hip width, standing height, shoulder width, and sitting height. For all races, girls under 10 or 11 yr. and above 15 yr. weighed less and were shorter in both standing and sitting height than boys of the same age, but from 10 or 11 until 14 or 15 yr. weighed more than the boys and were taller in both sitting and standing height. In general, shoulder widths were about the same for boys and girls of the same age in each race. Where differences occurred the measurements for the boys were greater than for the girls, except among 12- and 13-year-old Negroes, the girls of whom exceeded the boys. Girls above 8 or 9 yr. were wider through the hips than boys of the same age, and the differences were more pronounced after 11 or 12 yr. of age.

The white and Mexican children were more alike in their rates of growth in each of the five measurements than were the Negroes, who exceeded the other two race groups in every measurement except hip width of boys, which was the same for all three races. Larger weight gains between 10 and 14 yr. than for other ages were evident in all races, but more conspicuous for Mexican and Negro than for white children. There were more marked differences between average measurements of boys and girls in the Negro than white and Mexican children. Negro children were shorter in standing height and lighter in weight than white children in the age group from 7 to 9 or 10 yr. but taller and heavier above 10 yr. At all ages Negroes were shorter, broader of shoulder, and narrower of hip than white children. The Mexican children were

shorter in standing and sitting height, lighter in weight, and slightly narrower through the shoulders and hips than white children of the same age. In comparison with Negroes of the same age, the Mexican children were lighter in weight, shorter in standing height, and narrower in shoulder width but similar in both sitting height and hip width.

These findings are thought to indicate without question that growth standards for white children should not be used for Mexican or Negro children. A comparison of the data of the present study in the reports of similar studies of comparable groups revealed some striking similarities, as well as certain differences which led the author to comment that "more studies with technics standardized and other conditions as uniform as possible are needed."

Basal metabolic rate in children with abnormal bodily dimensions, M. DE BRUIN (*Amer. Jour. Diseases Children*, 57 (1939), No. 1, pp. 29-51, figs. 13).—Basal metabolic rates were determined with the Dussier de Barenne and Burger apparatus for 107 children between 1 and 15 yr. of age with abnormal bodily dimensions. The values obtained were interpreted by comparison with the basal metabolic rates of 243 normal children plotted in curves according to the body weight. For determining the basal metabolic rates of children of abnormal size, the rate is based on the actual weight for a well-proportioned child who is too tall or too small for his age, for a thin child, and for a boy with an excess of weight up to 35 percent and a girl with an excess of weight up to 20 percent. For children of greater weights the basal metabolic rate is based on the standard weight for the actual height increased by one-third of the excess over the standard weight.

The results of vitamin and hormone research, II, edited by E. MELLANBY and L. RUZICKA (*Ergebnisse der Vitamin-und Hormonforschung*, Leipzig: Akad. Verlagsgesell., 1939, vol. 2, pp. XV+520, figs. [92]).—Following the plan of volume 1 (E. S. R., 79, p. 422), this volume is composed of a foreword by the editors and the following review papers: Vitamins and Dental Caries, by M. Mellanby and J. D. King (pp. 1-54); The Chemistry of the Antirachitic Vitamins [trans. title], by H. Brockmann (pp. 55-103); Physiology and Pathology of the D Vitamins [trans. title], by E. Rominger (pp. 104-159); The Chemistry of Ascorbic Acid (Vitamin C) and Its Analogues, by W. N. Haworth and E. L. Hirst (pp. 160-191); The Physiological Importance of Manganese and Other Trace Elements in Organisms [trans. title], by G. Bertrand (pp. 192-212); Chemistry and Biological Properties of the Carcinogenic Substances, by J. W. Cook (pp. 213-258); The Relationships Between the Sex Hormones and the Formation of Cancer [trans. title], by A. Lacassagne (pp. 259-296); The Chemistry and the Secretion of Insulin [trans. title], by B. A. Housay and V. Denlofeu (pp. 297-346); The Physiology and Chemistry of the Plant Growth Hormones [trans. title], by A. J. Haagen-Smit (pp. 347-380); The Chemistry of the Flavins [trans. title], by P. Karrer (pp. 381-417); and The Bisexual and Other Effects of Pure Male Sexual Hormones on Females, by V. Korenchevsky (pp. 418-468).

Concerning the toxicity of vitamin A, E. B. VEDDER and C. ROSENBERG (*Jour. Nutr.*, 16 (1938), No. 1, pp. 57-68).—In three series of tests, groups of healthy rats were placed on a diet of Purina dog chow, supplemented by 25,000, 50,000, and 100,000 International Units of vitamin A per gram in the form of jewfish (*Stercolepis gigas*) liver oil, which also supplied from 4,500 to 5,000 I. U. of vitamin D. In a further series, the jewfish liver oil contained 530,000 I. U. of vitamin A, and four fractions obtained by molecular distillation contained from 248,000 to 865,000 I. U., the residue containing 53,000 I. U. of vitamin A per gram. The rats were kept on experiments for

100 days, and the toxic symptoms looked for included retarded growth, eye and nose hemorrhages, rales in the chest, and bone lesions. No sample of the oil was toxic in amounts supplying less than 33,000 I. U. of vitamin A daily, and the toxicity of one lot began at 66,000 I. U. The molecular distillation of the oil apparently separated the toxic substances from the vitamin A. While the addition of vitamin D₂ did not counteract the toxicity, vitamin D had only a partial effect. Five mg. of ascorbic acid daily almost completely counteracted the toxicity of the oil in 11 out of 12 rats receiving the supplement.

Experimental vascular disease in rats produced by multiple depletions of vitamin A. L. OPPER (Univ. Ark.) (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 3, pp. 449, 450).—In a preliminary study, all but 3 of 24 rats depleted two or three times of vitamin A and given carotene to recover from the recurrent depletions showed some degree of vascular injury. Histological examination revealed degenerative changes in the medial process, affecting almost the entire arterial system, with the exception of arteries within the stroma of the liver, kidney, and spleen. In advanced stages complete closure of the small visceral arteries resulted in myocardial fibrosis.

Vascularization of the cornea of the rat in riboflavin deficiency, with a note on corneal vascularization in vitamin A deficiency. O. A. BESSLEY and S. B. WOLBACH (*Jour. Expt. Med.*, 69 (1939), No. 1, pp. 1-12, pls. 4).—Rats maintained on a riboflavin-deficient diet consisting of alcohol-extracted casein 18 percent, Osborne and Mendel salt mixture 4, cod-liver oil 2, sugar 20, alcohol-extracted cornstarch 48, and peanut oil 8 percent were given 40γ of thiamin on alternate days and 2 gm. of riboflavin-free yeast extract daily after the first 10 days.

The rats ceased to grow after 3 weeks, and by the end of the fourth week a marked radial ingrowth of capillaries into the cornea from the vessels of the limbus occurred without any noticeable change in the cornea or any diminution in the transparency. By the tenth or eleventh week the blood vessels extended inward for more than one-third of the diameter of the cornea. The administration of 60γ riboflavin by mouth cleared the turbidity of the cornea within from 12 to 48 hr., while a 20-γ dose daily reduced the number and size of the capillaries in the cornea by the seventh day. After 12 days the vessels could not be seen, and all evidences of degenerative changes of the epithelium and of the tunica propria had disappeared. The condition is described as very similar to the vascularization of the cornea in vitamin A-deficient rats, except that the ingrowth of capillaries occurs concurrently with the epithelial changes in vitamin A deficiency.

The initiation and repair of the condition is suggested for use in testing the biological activity of compounds structurally related to riboflavin.

Night-blindness treated with vitamin A. C. VAILLANT and L. GILLIS (*Lancet [London]*, 1939, I, No. 3, pp. 149, 150).—In this case of night blindness in a young woman, at the end of the first fortnight of treatment with 10,000 International Units of vitamin A daily there was a slight improvement in the biophotometer readings but no improvement in symptoms. At the end of the second fortnight the biophotometer readings were normal and there was marked improvement in the night vision and in general health. On 5,000 I. U. of vitamin A daily the subject has since been able to maintain a satisfactory night vision. As the previous diet history was good and other members of the family on the same diet did not suffer from night blindness, the condition was attributed to faulty utilization of vitamin A rather than to the diet.

Evidence of another factor in the B complex for rats. W. R. WYATT. (Iowa State Col.). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 2, pp. 281-

283).—In an investigation of the possible multiple nature of the filtrate II factor prepared as described by Lepkovsky et al. (E. S. R., 76, p. 839), it is reported that the rat requires at least two factors in addition to vitamin B₁, flavin, nicotinic acid, and vitamin D₂. One of these factors is contained in alfalfa and the other in fuller's earth adsorbate from rice polish extract (fraction 8B) and in molasses and yellow corn. The 8B factor differs from the chick antidermatitis factor, the antiparalytic factor of Morgulis et al. (E. S. R., 81, p. 89), the chick growth factor U of Stokstad and Manning (E. S. R., 80, p. 814), and factor W described by Frost and Elvehjem (E. S. R., 79, p. 137).

New technic for the biological determination of vitamin B₁ with the full-grown pigeon and determination of the comparative vitamin value of the international standard of vitamin B₁ and of pure synthetic vitamin B₁ hydrochloride [trans. title], L. RANDOIN and P. LE GALLIC (*Compt. Rend. Soc. Biol. [Paris]*, 128 (1938), No. 23, pp. 1052-1054, figs. 2).—The authors call attention to the fact that in an earlier attempt (E. S. R., 72, p. 884) to determine the vitamin B₁ value of the fuller's earth adsorption product then used as international standard for this vitamin, the basal diet was lacking in other B vitamins as well as in vitamin B₁. Consequently the standard has been re-evaluated and compared with synthetic vitamin B₁ hydrochloride by a new method in which full-grown pigeons were again used, but with a synthetic diet lacking only in vitamin B₁ and with the end point in the preventive tests the numbers of days in which a given dose is capable of maintaining the body temperature of the test pigeon at 41.5° [C.] or above. The diet consisted of casein 6, fibrin 5, albumin 5, butterfat 4, and dextrin 66 parts, all in purified form, and salt mixture 4, agar agar 8, and filter paper 2 parts, with distilled water ad libitum and yeast heated 5 hr. in the autoclave at 120°, 2 gm. per bird daily. Each bird was given 18 gm. of basal diet daily by gavage, together with the autoclaved yeast and a given amount of the test material. The temperature was taken under the wing.

From tests on nine lots of pigeons for each test material, the physiological unit of vitamin B₁, as previously defined, was found to correspond to 35% of the international fuller's earth standard and to 12γ of the pure vitamin B₁ hydrochloride. Consequently the International Unit of vitamin B₁ was calculated to correspond to the activity of 3.1γ of synthetic vitamin B₁ hydrochloride.

New technic for the biological determination of vitamin B₁ with the young rat and determination of the comparative vitamin value of the international standard of vitamin B₁ and pure synthetic vitamin B₁ hydrochloride [trans. title], L. RANDOIN and P. LE GALLIC (*Compt. Rend. Soc. Biol. [Paris]*, 128 (1938), No. 23, pp. 1055-1057, figs. 2).—Parallel with the studies noted above, the fuller's earth adsorbate of vitamin B₁ and crystalline vitamin B₁ hydrochloride were compared by experiments on young rats in which, after a preliminary depletion period on a diet deficient only in vitamin B₁, given amounts of the test substance were administered in graded doses to groups of three rats for each dose, and curves plotted for the mean velocity of growth for each group during a 6-week period as ordinate against the dose of the test substance as abscissa. The vitamin B₁ activity of the test substance was taken as the weight of the substance corresponding to the abscissa of the maximum curvature as thus plotted. This corresponded to 14.5 mg. of the adsorption product and 4.5γ of crystalline vitamin B₁ hydrochloride. From these figures the International Unit of vitamin B₁ corresponded to the activity of 3.1γ of

synthetic vitamin B₁ hydrochloride, or exactly the same value as determined by the new pigeon test.

A standardized method for the determination of vitamin B₁. G. C. SUPPLE, R. C. BENDER, and L. C. BARCOCK (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 11, pp. 636-638).—The method described is essentially a refinement and simplification of the rat curative method of Smith as modified by Ammerman and Waterman (*E. S. R.*, 76, p. 423). Emphasis is placed on the necessity of using a comparatively simple basal diet supplemented with either pure entities or proved concentrates as sources of the other dietary essentials, of maintaining uniformly satisfactory physical conditions of the test animals, in spite of the necessity of keeping them at substantially constant weight, of selecting for the test animals showing the same degree of polyneuritis, and of always using the same degree of stimulation in determining whether or not cure has been effected.

The results of the application of the method in a critical and comparative study of vitamin B₁ reference standards are reported and discussed. Vitamin B₁ crystals in the dosage of 3γ now adopted as the International Unit gave cures of paralytic symptoms in 75 percent of 57 trials. The U. S. P. standard clay and the international standard clay adsorption products proved curative in 75 percent of 28 trials and 89 percent of 18 trials in doses of 12 mg. each.

Electrocardiographic changes in vitamin B₁ deficiency. C. C. DUSTIN, II. WEYLER, and C. P. ROBERTS (*New England Jour. Med.*, 220 (1939), No. 1, pp. 15-21, figs. 7).—Case reports, with electrocardiograms, are given for six male patients ranging in age from 34 to 50 yr., all of whom had histories of unbalanced diets with habitual use of alcoholic beverages. All presented clinical evidence of vitamin B₁ deficiency and abnormal electrocardiograms that might have been interpreted as indicative of serious myocardial disease. Under a high vitamin regime with vitamin B₁ medication, all of the patients recovered within a few weeks, during which repeated electrocardiograms at rather close intervals showed a tendency to return to normal. It is pointed out that if the clinical conditions had not been known the interpretation of the electrocardiograms in some cases might easily have been entirely incorrect.

Vitamin values of garden-type peas preserved by frozen-pack method.—I, Ascorbic acid (vitamin C), E. N. TODHUNTER and B. L. SPARKLING. (Wash. State Col.). (*Food. Res.*, 3 (1938), No. 5, pp. 489-498).—In continuation of previous studies (*E. S. R.*, 78, p. 136), the authors determined the ascorbic acid content and distribution in frozen-pack peas of the Telephone variety, sieve size No. 6, subjected to scalding at different temperatures and for varying periods of time before freezing and of eight other varieties of frozen-pack peas obtained from a commercial canning plant. The Muculin and King modification (*E. S. R.*, 77, p. 743) of the indophenol titration method was followed, and the results were checked by the modified rat bio-assay method of Sherman et al. as previously described (*E. S. R.*, 78, p. 136).

The following mean values were reported for the ascorbic acid content of the peas scalded under different conditions: In steam at 99° C. for 1 min. 0.183 mg. of ascorbic acid per gram; in water at 99° for 1 min. 0.21, for 2 min. 0.185, and for 3 min. 0.17; in water at 88° for 2 min. 0.212, for 4 min. 0.232, and for 6 min. 0.225; in water at 71° for 2 min. 0.081, for 4 min. 0.072, and for 6 min. 0.091 mg. of ascorbic acid per gram. Peas scalded in water 1 min. at 99° after 4 hr. of storage at 21° had a mean content of 0.161 mg. and after 8 hr. of storage 0.206 mg. of ascorbic acid per gram. The mean ascorbic acid content of the seed coats was 0.207 mg. and of the cotyledon 0.137 mg. per gram. Immediately after thawing the peas had a mean ascorbic acid content of 0.17 mg.,

after 30 min. at room temperature had lost 15.9 percent, and after 60 min. the loss was 27.1 percent. Peas which were thawed and then placed in the refrigerator at 4.5° for 24 hr. lost 24.7 percent of their ascorbic acid content.

Compared with the Telephone variety, frozen-pack peas, sieve size 6, of the Thomas Laxton, Laxtonian, Dwarf Alderman, and Duplex varieties showed no significant difference in ascorbic acid content; Improved Gradus was definitely richer; and Laxton Progress, Rogers 95, and Asgrow 40 contained significantly less of the vitamin. The mean ascorbic acid content of the nine varieties ranged from about 0.113 to 0.294 mg. per gram.

Losses of vitamin C during the cooking of certain vegetables, F. FENTON and D. K. TRESSLER. (Cornell Univ. and N. Y. State Expt. Sta.). (*Jour. Home Econ.*, 30 (1938), No. 10, pp. 717-722).—This summarizes the results of a series of studies previously noted (*E. S. R.*, 81, p. 146).

The vitamin C content of Estonian honeys [trans. title], M. KASK (*Ztschr. Untersuch. Lebensmitl.*, 76 (1938), No. 6, pp. 543-545).—Data are reported on the ascorbic acid content, as determined by indophenol titration, of 160 samples of Estonian honey, 144 of which were unadulterated, 9 adulterated with invert sugar, and 7 with corn sirup. The ascorbic acid content of the unadulterated honeys ranged from 0 to 20 (average of 4.88) mg. per 100 gm. with 73 of the samples within the range of from 2 to 5 mg. and 6 from 10 to 20 mg. The samples containing invert sugar ranged from 0.8 to 4.2, with an average of 1.6 mg. per 100 gm., and those containing corn sirup from 4.8 to 30.7, with an average of 12.9 mg. per 100 gm. No explanation is offered for the high content of the latter samples, but it is noted that the samples low in vitamin C were for the most part light colored and those high in vitamin C brown to dark-brown in color. Among the latter were 4 samples of pine-needle honey, and attention is called to the fact that pine needles have been shown to be very rich in vitamin C.

Analyses are also reported for a varying number of samples of honey of the 1934, 1935, 1936, and 1937 crops. On the basis of the average value of the 1937 crop as 100 percent, the corresponding values for the preceding years decreased to 48.6 percent for 1934. This is considered to represent roughly the loss in the vitamin C content of honey on storage at room temperature and to indicate that honey is a relatively stable medium for vitamin C.

The vitamin C content of Chinese foods, II, T. J. CHU and B. E. READ (*Chin. Jour. Physiol.*, 13 (1938), No. 3, pp. 247-255).—In this continuation of an earlier study (*E. S. R.*, 74, p. 134), the vitamin C content of 80 Chinese foods was determined by both iodine and indophenol titration. The data are tabulated by food groups, with comparative values for a few foods as reported in the literature. The materials tested included cereals and cereal products; legumes and legume products; roots, greens, and other vegetables; cucurbits; fresh fruits; nuts, seeds, and dried fruits; vegetable products (sesame paste and lotus root starch); meats, including liver, brain, heart, gizzard, tongue, blood, and muscle flesh; and marine foods. Attention is drawn particularly to the vitamin C content of dried black soybeans 0.4666 mg. per gram by indophenol titration, fennel 0.506, laver (seaweed) 0.611, bitter gourd 0.5646, and black sesame seed 0.3828 mg. per gram.

The vitamin C content of the blood plasma in normal and sick children, F. T. CHU and C. SUNG (*Chin. Med. Jour.*, 52 (1937), No. 6, pp. 791-806, figs. 3).—As a basis for interpreting blood plasma values of vitamin C in infants and children, simultaneous analyses were made of urine and blood plasma for periods of from 11 to 19 consecutive days in eight infants and children weighing from 6.1 to 23.3 kg. The subjects were kept for a control period of

several days with no addition of vitamin C and then were given daily doses, either as ascorbic acid or orange juice, of about 10 mg. per kilogram of body weight until a state of relative saturation was reached, when about 30 to 50 percent of the test dose was excreted in 24 hr. The periods immediately preceding and following this period were designated as the presaturation and post-saturation stages, respectively. If there was no appreciable response to the test dose in the first 3 days, the subject was considered to be in a deficient or unsaturated state. The determination of the ascorbic acid of the urine was made by the Harris and Ray method and of the blood plasma by the Farmer and Abt method, with tungstic acid for deproteinization (E. S. R., 74, p. 135).

The ranges in ascorbic acid content of the blood plasma corresponding to the different stages of saturation, as determined by urinary excretion, were from 0.17 to 0.41 mg. per 100 cc. for the deficiency or unsaturated stage, from 0.54 to 0.8 for the presaturation, from 0.86 to 1.36 mg. per 100 cc. for the saturation, and from 0.85 to 1.25 mg. for the post-saturation stages. In subsequent plasma tests, all of 11 breast-fed infants gave values of more than 0.5 mg. per 100 cc., while 22 artificially fed infants who had received cow's milk, with and without the addition of cereals and a small amount of dilute cabbage water, gave values ranging from 0.168 to 0.342 mg. per 100 cc. Six artificially fed infants without febrile or infectious diseases were given large doses of vitamin C either as orange juice or ascorbic acid and their blood plasma was analyzed from time to time, with resulting slow and steady increase in ascorbic acid content. Low values were found in infants with acute bacillary dysentery and active tuberculosis even when rather liberal amounts of fruit juices were given.

The authors conclude that the examination of the ascorbic acid content of the blood plasma offers decided advantages over analysis of the urine, particularly because the level of ascorbic acid in the blood shows a gradual and steady increase following vitamin treatment rather than the abrupt change in the urine only at the point of saturation.

Correlation between vitamin C content and complement titer of human blood plasma, F. T. CHU and B. F. CHOW (*Soc. Expt. Biol. and Med. Proc.*, 38 (1938), No. 5, pp. 679-682, figs. 2).—To determine whether or not the serum complement of human subjects can be increased by the administration of vitamin C, simultaneous determinations of complement and ascorbic acid were made over extended periods of time on two children and one woman who were hospitalized but not suffering from febrile, diarrheal, or other diseases which might influence the metabolism of vitamin C and whose intake of vitamin C was raised or lowered during the experimental period by the addition of ascorbic acid to, or its withdrawal from, a constant basal diet. In a second group of 38 patients of different ages suffering from various diseases, single simultaneous determinations of complement and ascorbic acid were made.

The complement and ascorbic acid content data obtained for the first group, when plotted for each subject, showed that the increase in ascorbic acid content of the diet was followed by a rise in complement, as well as in the ascorbic acid content of the plasma, and a decrease by a fall in both. The range of fluctuation, however, was smaller for complement than for ascorbic acid. The values for ascorbic acid in the second group were divided into three classes of deficiency, presaturation, and saturation according to the classification of Chu and Sung as noted above, and corresponding values of complement are presented in a scatter diagram.

The low complement titer values were with few exceptions associated with the deficiency class and the high ones with the saturation class. It is concluded that there is a qualitative relationship between vitamin C intake and complement titer in human plasma, although an adequate explanation of the phenomenon is not clear at present.

Histological investigation of the behavior of vitamin C in various organs during wound healing [trans. title], H. J. LAUBER and W. ROSENFELD (*Klin. Wchnschr.*, 17 (1938), No. 45, pp. 1587, 1588).—A summary is given of the results obtained in the histological examination by the silver nitrate reduction method of Giroud and Leblond (*E. S. R.*, 77, p. 152) of the adrenals, hypophysis, and reproductive organs of normal guinea pigs and of guinea pigs on vitamin C-deficient and vitamin C-rich diets in which wounds had been produced at the beginning of the experiment. In the animals on the vitamin C-deficient diets the content of ascorbic acid was very low, and none was detectable in the skin or wound tissues, granulation of the wounds was late in forming, and the animals had infections of greater or less degree. In the animals on a normal diet enriched with 100 mg. daily of Redoxon the content of ascorbic acid in the various organs was high, granulation of the wounds was rapid, and ascorbic acid was present in the granulations and adjacent skin.

Investigations on the latent deficiency in ascorbic acid [trans. title], E. COVILLE, H. SIMONNET, and J. MORNARD (*Presse Méd. [Paris]*, 46 (1938), No. 95, pp. 1745-1748).—The authors report a series of studies undertaken to determine the extent of occult or latent vitamin C deficiency in a group of young adults from 20 to 30 yr. of age living on a diet considered normal, and the quantities of ascorbic acid necessary to saturate the subjects.

The Rotter intradermal test (*E. S. R.*, 78, p. 571), with slight modifications, was first applied to nine subjects on the diet without ascorbic acid supplement, to five on the same diet supplemented with 100 mg. ascorbic acid daily for 15 days, and to five others who had received an ascorbic acid supplement of 500 mg. daily for 6 days. Of the first group only two, of the second none, and of the third all required not more than 5 min. for disappearance of the color and were thus considered normal with respect to ascorbic acid saturation. The daily output of ascorbic acid was then determined of subjects of the same age group, in the same mode of life and on identical diets supplemented by 100 mg. of ascorbic acid in one group of nine subjects, 250 in another of five, and 500 mg. in a third of five subjects.

At the end of 30 days the range in daily excretion of ascorbic acid in the first group was from 4 to 20.7 mg. as compared with from 1.6 to 15.4 mg. for the same subjects before beginning the saturation tests. In the second group a marked increase in the quantity of ascorbic acid excreted took place on the fourth, fifth, sixth, and seventh days, respectively (two subjects), and in the third group on the third day (two subjects), fourth and fifth days (two subjects). Experiments are also reported showing that pure ascorbic acid is as effective, as judged by urinary excretion, as an equivalent quantity administered as lemon juice, that the increased elimination of ascorbic acid after saturation drops very rapidly when the treatment is stopped, and that on resumption of the treatment the response in increased elimination is more rapid than the original response. In two subjects tested at frequent intervals during the 24 hr. following the ingestion of 250 mg. of ascorbic acid, the excretion was at its height at the end of 6 hr.

The authors conclude that the adult's requirement for vitamin C is as much as 100 mg. daily, an amount seldom reached in ordinary diets, particularly at certain times of the year. Because of the important role played by ascorbic

acid, not only in the prevention of scurvy but in the defense of the organism against infectious diseases, it is thought to be essential to supplement with ascorbic acid the diet of collective groups (public institutions, the army, etc.).

A comparison of methods for detecting and grading subclinical scurvy, R. A. SLOAN (*Jour. Lab. and Clin. Med.*, 23 (1938), No. 10, pp. 1015-1026, figs. 6).—The observations made on 16 scorbutic patients, 2 nonscorbutic patients with bleeding, and 5 normal subjects included, in addition to clinical symptoms and dietary history, (1) capillary resistance tests by the negative pressure technic of Dalldorf (*E. S. R.*, 70, p. 728) and by a modification of the method, which consisted in raising the pressure to 45 cm. of mercury and taking readings immediately before and at 5-min. intervals after the intravenous injection of a test dose of the vitamin and comparing the amount of hemorrhage at the various intervals; (2) urinary ascorbic acid in fresh acidified fasting samples, in 24-hr. specimens before intravenous medication and during oral administration, and in 6-hr. specimens following a test dose of 15 mg. per kilogram of body weight administered by intravenous injection; and (3) blood ascorbic acid by methods similar to the Farmer and Abt macromethod (*E. S. R.*, 74, p. 135) but with proportions of the reagents requiring less dilution of the plasma. In addition to fasting values, blood absorption curves were obtained by analyses of specimens at frequent intervals following the injection of the vitamin.

For the 5 subjects considered normal, the extremes in the values reported were capillary resistance 30 and 55 cm. of mercury negative pressure, fasting urine 0.97 and 14 mg. per 100 cc., 6-hr. urine 41 and 46, fasting blood 0.62 and 1.06, and 4-hr. blood absorption 1.95 and 2.1 mg. per 100 cc., respectively. For the 16 patients suffering from scorbutic symptoms in varying degrees from bleeding gums to severe scurvy with extensive bleeding into the skin and bowels, high, average, and low values before and after treatment with ascorbic acid were capillary resistance 40, 24, and 5 cm. mercury negative pressure before, and an average of 45+ cm. after ascorbic acid treatment; fasting urine 1.9, 0.58, and 0.3 mg. and 5.51, 2.55, and 0.86 mg. per 100 cc.; 6-hr. urine 28, 16, and 2 mg. and 70, 49, and 32 mg.; fasting blood 0.55, 0.28, and 0.06 mg. and 1.49, 1.04, and 0.45 mg.; and 4-hr. blood absorption values 1.59, 0.98, and 0.09 mg. per 100 cc. before and 2.4, 1.86, and 1.2 mg. per 100 cc. after treatment.

In the opinion of the author the capillary resistance test in the majority of cases gives dependable information concerning the presence or absence of vitamin C depletion, but does not indicate the degree of depletion and has one great drawback in the occurrence of falsely negative results due to severe anemia. The examination of a single fasting specimen of urine is not a safe criterion of subclinical or even mild scurvy, but the saturation test gives very satisfactory results with no overlapping. Fasting blood values serve in a rough way to indicate the degree of deficiency but with considerable overlapping, and blood saturation curves give very satisfactory results.

Stability of vitamin D in irradiated evaporated milk, C. H. KRIEGER and H. T. SCOTT (*Food Res.*, 3 (1938), No. 3, pp. 283-286).—Using the U. S. P. XI (1936) method, the vitamin D potencies of triplicate samples of irradiated evaporated milk from 22 plants were determined at intervals up to almost 3 yr. after packing. The milk samples assayed close to 135 U. S. P. units of vitamin D per quart when diluted 1:1 with distilled water at time of arrival at the plant. At the end of 1 yr. there was no loss of potency, and after 2 or 3 yr. of storage under moderate temperature changes there was only a slight decrease in vitamin D potency in seven samples within the limits of error of biological assay. Since the average elapsed time between the packing of the

milk and its consumption in the home is from 30 to 90 days, the vitamin D potency of irradiated evaporated milk is assured.

Radiographic demonstration of protection by vitamin D against meta-phyeal decalcification in adult rats on high calcium-low phosphorus diet. B. O'BRIEN and K. MORGAREIDGE (*Jour. Nutr.*, 16 (1938), No. 1, pp. 91-102, figs. 5).—By means of a simplified technic, the effects of high calcium, low phosphorus diet No. 2965 of Steenbock and Black were demonstrated radiographically on adult rats during a 52-week period. The radiographic evidence was checked by bone ash analyses of the femurs. It was found that the structures of the proximal end of the tibias are particularly sensitive to changes in mineral metabolism which affect calcification. The addition of vitamin D during the last 18 weeks of the experiment markedly improved the decalcified condition of the skeleton, but the administration of vitamin B complex and of vitamin A had no demonstrable effect.

TEXTILES AND CLOTHING

Progress in methods of wool research. V. BOSMAN (*Farming in So. Africa*, 13 (1938), No. 151, pp. 397-400, figs. 4).—Methods and apparatus for determining the fineness, tensile strength, resilience, and durability of wool fibers are described, and other wool and body characteristics and statistical methods are briefly discussed.

A study of certain physical properties of various kinds of wool fibers and fabrics. E. PIERSON (*South Dakota Sta. Rpt. 1938*, pp. 32, 33).—The complete report on this study, which has been noted previously (*E. S. R.*, 70, p. 572), is summarized. In comparison with the wool of Hampshire, Rambouillet, Shropshire, and Southdown breeds of sheep the tailless fiber ranked intermediate. The tailless fabrics were superior to the other fabrics in tensile strength and bursting strength.

HOME MANAGEMENT AND EQUIPMENT

The farm-housing survey (*U. S. Dept. Agr., Misc. Pub. 323* (1939), pp. 42, pl. 1).—The data obtained in 1934 from a house-to-house canvass of 595,855 farms in 46 States are grouped geographically into nine divisions and presented in tabular form, showing the acreage of the farms, distribution of owners, non-owners, white and nonwhite operators; age and material of houses; size of house, room use, and number of occupants; water supply and sewage disposal; houses lighted by gas or electricity, central heating systems, refrigeration, types of cook stoves, and power washing machines; condition of house structure; and the reactions of householders to the question of borrowing money for home improvement at a satisfactory rate, with repayments distributed over a 10-yr. period. The data are compared with the 1930 and 1935 agricultural census data. The appendix contains the schedules used in obtaining the information and the general instructions to the enumerators.

Housing requirements of farm families in the United States. M. WILSON (*U. S. Dept. Agr., Misc. Pub. 322* (1939), pp. II-40, fig. 1).—Based on the data contained in the report noted above, this publication contains information of use to designers and property owners in planning low-cost farm houses suited to the needs of the family and the climate, major land uses, and size and type of farms in every region of the United States.

Planning the kitchen. M. WILSON (*Oregon Sta. Circ. 131* (1939), pp. 32, figs. 26).—Some of the information contained in a previous bulletin (*E. S. R.*, 80, p. 431) is condensed for presentation in this circular. The kitchen-planning suggestions made include designs for cabinets, floor plans and minimum dimen-

sions for free floor areas, and descriptions of the centers needed in the average farm kitchen for food preparation, dining, ironing, planning, and child care and play.

MISCELLANEOUS

Toward better agriculture: [Biennial Report of California Station, 1937-38], C. B. HUTCHISON and S. B. FREEBORN (*California Sta. [Bien.] Rpt. 1937-38*, pp. X+211, pls. 16).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Annual report of the director [of the Delaware Station] for the fiscal year ending June 30, 1938, C. A. McCUE ET AL. (*Delaware Sta. Bul. 214 (1938)*, pp. 45, figs. 3).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Golden Anniversary Report [of Florida Station], 1938, W. NEWELL ET AL. (*Florida Sta. Rpt. 1938*, pp. 198+VIII, figs. 20).—The experimental work not previously referred to is for the most part abstracted elsewhere in this issue.

Fifty-seventh Annual Report of the New York State Agricultural Experiment Station, [1938], P. J. PARBOTT (*New York State Sta. Rpt. 1938*, pp. 44).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Annual Report of the South Dakota Agricultural Experiment Station, [1938], J. W. WILSON ET AL. (*South Dakota Sta. Rpt. 1938*, pp. 55).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Forty-eighth Annual Report [of the Washington Station], 1938, E. C. JOHNSON ET AL. (*Washington Sta. Bul. 368 (1938)*, pp. 103).—The experimental work not previously referred to is mostly noted elsewhere in this issue.

State and Federal agricultural publications applicable to Tennessee Valley area (*U. S. Dept. Agr., 1939*, pp. [1]+88).—This is a classified list of publications of the U. S. Department of Agriculture and the experiment stations and extension services of the States in the Tennessee Valley area (*U. S. R., 80*, p. 433).

Farm Research, April 1, 1939 (*Farm Res. [New York State Sta.], 5 (1939)*, No. 2, pp. 12, figs. 5).—In addition to articles noted elsewhere in this issue, this number contains the following: Apply Nitrogen to Apple Orchards Now for Best Results, by R. U. Collison (p. 3); Believes New York State Cheese Industry Has Promising Future, by M. W. Yale (pp. 10, 11); and Long List of Weed Seeds Found in Alfalfa and Clover Seed, by M. E. Woodbridge (p. 12).

Bimonthly Bulletin, [March 1939] (*North Dakota Sta. Bimo. Bul., 1 (1939)*, No. 4, pp. 51, figs. 6).—In addition to articles noted elsewhere in this issue and brief abstracts of current contributions to agricultural science, this number contains Crop Production and Disease Control—Wheat, by H. L. Bolley (pp. 30, 31).

Report on agricultural research in Great Britain (London: P E P (*Polit. and Econ. Planning*), 1938, pp. [6]+146, [fig. 1]).—This report is discussed editorially on page 161 of this issue.

NOTES

Colorado College and Station.—Dr. E. P. Sandsten, dean of agriculture and director of the station, and E. B. House, head of the department of irrigation engineering, retired June 30. The former was succeeded by Dr. C. H. Kick, head of the department of animal industry, and he in turn by H. B. Osland, with R. C. Tom serving as acting head until Mr. Osland's return from leave of absence. J. R. Miller, station editor, has been appointed secretary of the State Board of Agriculture and has been succeeded by Marvin Russell.

Connecticut University and Storrs Station.—Effective July 1, an act of the legislature changes the name of the institution from Connecticut State College to University of Connecticut.

Arrangements for cooperative research have been made between the station department of genetics and the department of gynecology of the Rothschild-Hadassah Hospital, Jerusalem, Palestine.

Delaware University and Station.—The retirement on July 1 is noted of Dr. C. A. McCue, dean and director since 1920 and connected with the institution since 1907. George L. Shuster, professor of agronomy and research agronomist, has been appointed director.

Purdue University and Indiana Station.—Dean and Director J. H. Skinner retired on June 30, terminating a service at the university of approximately 40 years. He has been succeeded by H. J. Reed, assistant director of the station, as dean of the School of Agriculture and director of the station and agricultural extension, with T. A. Coleman as associate director of extension and V. C. Freeman as associate dean.

Kansas College and Station.—The college will receive a total of \$2,208,330 in State funds during the ensuing biennium, a decrease from \$2,405,199. Included in the allotments are \$103,400 for the four substations, \$30,000 for veterinary research, and \$42,000 for the soil experimental fields.

Eva Stotts, recently appointed instructor in clothing and textiles, was fatally injured in an automobile accident on April 17. She was 31 years of age and a graduate of the University of Nebraska in 1930 and received the M. A. degree in 1937.

Rutgers University and New Jersey Stations.—Dr. William H. Martin, professor of plant pathology and plant pathologist, who has been serving as acting dean and director since the death of Dr. J. G. Lipman (E. S. R., 81, p. 1), has been appointed dean of the College of Agriculture and director of the stations.

Third Commission of the International Society of Soil Science.—This Commission, concerned with soil microbiology, is to meet in New Brunswick, N. J., from August 30 to September 1. It will thus immediately precede the International Congress for Microbiology, which opens in New York City on September 2. The program for August 30 will be devoted to legumes and legume bacteriology, and that on August 31 to the microbiology of soil organic matter and *Azotobacter* and its significance in soil processes. There will also be a conference on legume inoculants and on September 1 an excursion to some of the agricultural regions of New Jersey. Additional information may be obtained from Dr. R. L. Starkey, New Jersey Experiment Stations, New Brunswick, N. J.

EXPERIMENT STATION RECORD

VOL. 81

SEPTEMBER 1939

No. 3

FIFTY YEARS OF EXPERIMENT STATION RECORD

The current issue of the *Record* begins a new half century of service. It was in September 1889 that the Office, then under the direction of Dr. W. O. Atwater, undertook to meet the need which had been visualized in the 1888 report of the Commissioner of Agriculture for "a journal for the stations to contain accounts of their current research, abstracts of similar work in this and other countries, and other matters of mutual interest . . . , in short, a means to provide prompt and constant intercommunication between the stations and bring them from outside what they want to know." This journal appropriately received the title of *Experiment Station Record*.

At the time publication was begun, less than 2 years had elapsed since the first Federal payments to the States under the Hatch Act of 1887. However, experiment stations had been established under its provisions in 40 States and Territories, and in most of these publications had been issued or were under way. A Digest of Annual Reports of the Agricultural Experiment Stations for 1888 had also been prepared by the Office, but this did not include publications other than the annual reports, nor did it meet the need for frequent and regular assembling and summarizing of the considerable amount of new and much-needed information which the stations were bringing to light from day to day and disseminating more or less locally through diverse channels. Furthermore, it made no adequate provision for the furnishing to the stations of the "advice and assistance" contemplated by the Hatch Act, and gave no opportunity for the exercise of leadership by the Office in bringing the stations together and coordinating their work.

Volume 1, number 1, of the *Record* therefore was gotten out by the Office staff as the beginning of "a current record in brief outline of the results of experiment station and kindred work." Besides the abstracts of station literature, provision was made for including "brief accounts of the publications and work of this Department and such information for station workers and others interested in agricultural science as may from time to time be deemed advisable."

Editorial notes, later expanded into formal editorials, were begun in the second issue for the discussion of topics of direct interest to the stations, and news notes with volume 2 as "a helpful means for keeping the stations advised of one another's work and plans and for showing the general public more of the spirit and tendencies of the stations, the kinds of work they are doing, the aid and recognition they are receiving, and the advances they are making."

The need which was realized from the beginning of acquainting station and Department workers and others with current research in agricultural science outside the United States was met in part in 1890 by the inclusion of publications from Canadian institutions and a few months later by an extension to other foreign countries. During the next two decades this feature of the work was developed to the point of a reasonably complete coverage of the world's major findings in agricultural science.

The expansion in scope was accompanied by some condensation of abstracts, but was primarily made possible by an enlargement of space. Volume 1 dealt with some 280 reports and bulletins and, aside from indexes and tables of contents, contained 325 printed pages. Volume 20, published in 1908-9, consisted of 1,200 pages of comparable material including 5,336 abstracts. Three years later the two volumes which were being brought out annually contained a total of 7,841 abstracts and 1,800 printed pages of abstracts, editorials, and notes.

The 1912 maximum of 1,800 pages plus about 300 pages of indexes and contents continued without change until 1929, when the advancing cost of printing brought about the abolition of the detailed table of contents from each issue and a consequent reduction of about 100 pages per year. Nine years later similar causes led to a curtailment in the space available for abstracts. At that time a readjustment of printing costs resulted in the omission of an entire issue of 144 pages and an abridgment of 4 later issues by 16 pages each. Data recently compiled for the fiscal year ended June 30, 1939, indicate that the total shrinkage in space from the previous year has been over 200 pages, or 12 percent, while the total number of abstracts decreased from 7,218 to 6,746, a reduction of 6.5 percent.

Since the past quarter century has been a period of marked expansion of research agencies in the fields of agriculture and home economics, the problem of adequately covering the literature in the space available has become increasingly acute. Under the prevailing conditions, full coverage remains of the technical publications of the experiment stations and the Department and of the many contributions of the staffs of these agencies which find publication through scientific journals and other nonofficial mediums. Mate-

rial from other sources, however, is necessarily subject to an increasingly rigid selection.

The extent of the service which the *Record* has thus far rendered may be visualized in part by the fact that volumes 1-80 contain nearly 280,000 separate abstracts. The original articles included not only the entire scientific output of the Department and the approximately 50 State experiment stations, but hundreds of other research agencies and individuals, using more than a dozen languages and located all over the world.

Author and subject indexes have been provided from the beginning, and combined subject indexes have been issued for volumes 1-12, 13-25, 26-40, 41-50, 51-60, and 61-70. A similar combined index for volumes 71-80, covering the 5-year period ended last June, is in preparation. The total number of entries in the combined indexes as a whole probably far exceeds half a million.

The usefulness of so extensive and unique a compendium of information has long since been widely accepted. Although with the passing of the years the *Record's* own bulk has been an increasing handicap to its preservation by individuals, it has become well-nigh indispensable to libraries and many other institutions as a work of reference. The Office has cooperated in many instances in the completion of files for this purpose, and is still in a position to render considerable assistance in this direction. A moderate stock is even available for all of the combined indexes aside from that for volumes 13-25.

For obvious reasons, continuity of policy and consistency of treatment has been the rule in the management of the *Record*, but numerous innovations have been put into effect in recent years, notably the conserving of as much space as possible for abstracts by curtailment of the editorials and news notes and abstracts of the station annual reports. These changes were made in response to a questionnaire sent out to the experiment stations in 1931 and discussed in detail at that time (E. S. R., 66, p. 401). Other suggestions are always in order, and will receive full consideration from the point of view of increasing the effectiveness of the *Record* as far as possible with the means available.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

The chemical composition of rayless goldenrod (*Aplopappus hartwegi*), T. F. BUEHNER, C. M. MASON, and J. A. CROWDER. (Univ. Ariz.). (*Amer. Jour-Pharm.*, 111 (1939), No. 3, pp. 105-112, figs. 2).—*A. hartwegi* was found to contain an unusually high percentage of resins, the highest, namely, 25 percent, being found in the leaves, and approximately 8 percent in a composite of the entire plant. The essential oils, present to an extent of 1.24 percent in the entire plant, were found to conform to the empirical formula $C_{10}H_{16}$ and to have the properties of the menthene group of the terpene series. The chloroform extract from material digested with concentrated sodium hydroxide yielded hydrochlorides which reacted as typical alkaloids toward the usual reagents. The crystals obtained on evaporation were found to contain 4.31 percent nitrogen, which partially confirms the qualitative tests.

Pyridine is evolved when the plant material is steam distilled from strongly alkaline solution. Microscopic and chemical tests confirmed the presence of pyridine in the distillate. Quantitative analysis indicated 2.04 percent pyridine on the dry-plant basis.

Ouricury palm kernel oil, R. S. MCKINNEY and G. S. JAMIESON. (U. S. D. A.). (*Oil & Soap*, 15 (1938), No. 7, pp. 172-174).—Ouricury palm fruits from Florida, as well as the oil expressed from the kernels imported from Brazil, have been investigated. The fruits consisted of 47.5 percent of pulp and 52.5 percent of palm nut, of which the kernel amounted to 23.8 percent. On the basis of the whole fruit, the oil in the pulp amounted only to 0.9 percent. The kernels from Brazil contained 69.7 percent of oil, some of the characteristics of which were as follows: Saponification value 256.9, iodine number (Hanus) 14.69, thiocyanogen value 12.78, Reichert-Meissl value 5.93, Polenske number 18.38, and unsaponifiable matter 0.27 percent. The percentages of fatty acids found in the oil were as follows: Caproic 1.66, caprylic 9.10, capric 7.64, lauric 42.7, myristic 8.43, palmitic 7.15, stearic 2.15, arachidic 0.96, oleic 12.18, and linoleic acid 2.04 percent.

Attention is called to the importance of not assuming the presence in distilled ester fractions of the lower homologues of oleic acid from deductions made only from calculations using the iodine number and saponification value of the fraction without confirmation by other evidence. The present investigation has shown the danger of such assumptions.

Stillingia oil, G. S. JAMIESON and R. S. MCKINNEY. (U. S. D. A.). (*Oil & Soap*, 15 (1938), No. 11, pp. 295, 296).—An American stillingia oil expressed from combined California, Florida, and Texas seed gave an iodine number of 176.1, a saponification value of 211.7, a thiocyanogen value of 102.7, and the following percentages of acids: Oleic 7.7, linoleic 56.3, linolenic 24.6, palmitic 4.42, stearic 1.43, and arachidic acid 0.34. A sample of Chinese oil gave an iodine number of 169, a saponification value of 206.2, and a thiocyanogen value of

100.7, and the following percentages of acids: Oleic 10.4, linoleic 49.9, linolenic 25.4, palmitic 5.89, stearic 2.64, and arachidic acid 0.14. From the characteristics and composition of these samples it would appear that stillingia is suitable for use in the manufacture of paints and varnishes.

Action of wheat amylases on soluble starch. O. E. STAMBERG and C. H. BAILEY. (Minn. Expt. Sta.). (*Jour. Biol. Chem.*, 126 (1938), No. 2, pp. 479-488, figs. 4).—The authors obtained preparations designated α -amylases 1 and 2, respectively, from germinated wheat by direct alcohol precipitation and by alcohol precipitation following heat treatment. Precipitations designated β -amylases 1 and 2 were obtained from normal wheat by direct alcohol precipitation and by acid treatment of the extract followed by alcohol precipitation, respectively.

Hydrolysis of soluble starch by the β -amylase preparations was about 60 percent, by α -amylase 2 about 40 percent, and by α -amylase 1 and malt diastase about 85 percent, as determined by the reducing power in terms of available maltose. α - and β -amylase apparently attacked the same portion of the starch. With a yeast-manometric method and soluble starch as substrate the pure α -amylase 2 produced mainly nonfermentable reducing dextrins, together with some fermentable reducing sugars. The other enzyme preparations produced fermentable reducing sugars equivalent to the reducing value.

An electronic voltage regulator with supplementary circuit to supply low voltages. E. B. WORKING. (Kans. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 8, pp. 434, 435, figs. 2).—"To secure voltage regulation an approximately fixed voltage above the negative side of the line is established by means of a gas-discharge tube (a neon glow lamp with resistor removed from the base, or a type 874), in series with current-limiting resistors. This voltage is applied to the cathode of a tube of high amplification, such as type 6J7. A bleeder across the output which is to be regulated is tapped at a point which will be approximately 3 v. negative to the fixed voltage when the output is at the voltage desired, and this tap is connected to the grid of the 6J7. Any change in output voltage is thus amplified and is applied to the grid of a power tube, as a type 6L6, placed in the positive line to carry the entire output current." Details of a circuit based on this principle are described and shown in a hook-up diagram.

Antifoaming device for use in concentration of noninflammable liquors. E. A. GASTBOCK and J. D. RED. (U. S. D. A.) (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 8, p. 440, fig. 1).—The device described consists essentially of a loop of Nichrome wire helix attached to heavier copper leads and placed in the distilling flask above the liquid so that when electrically heated the coil breaks the foam bubbles before they come in actual contact with it by evaporating the film.

In the form of the device here illustrated, 88 cm. of 22-gage Nichrome wire were wound into a helix, the helix was bent into a circular loop, and its ends were attached to 16-gage copper leads, passing through the stopper of the distilling flask. The loop was placed in a 2-l. or larger, flask so that it might be spaced at least 4 cm. from the glass above it. The coil was heated from the 110-v. lines, a 500-w. heater being put in sockets as a control resistance, with another similar heating unit so connected as to be put in parallel with the first unit by closing a switch. The arrangement "has proved successful in the laboratory distillation and concentration of alkaline pulping liquors that foam excessively and should prove useful in the distillation of many aqueous foam-producing solutions. There appears to be no reason why it should not be applicable to large-scale apparatus."

A simple apparatus for the rapid determination of moisture by the carbide method, E. T. FUKUNAGA and L. A. DEAN. (Hawaii Expt. Sta.). (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 1, pp. 3-5, fig. 1).—The authors describe an apparatus consisting essentially of a gas-tight bomb equipped with a pressure gage in which the weighed soil sample is placed in the larger, and an excess of pulverized commercial calcium carbide in the smaller, of two separate containers. After gastight closure of the bomb the smaller container is upset to mix the carbide with the soil sample, and the moisture content is determined from the pressure and temperature readings. In all cases "a constant difference was found to exist between the two types of measurement. Consequently, the utility of the rapid method as an aid to irrigation control is suggested if the critical soil moisture constants of specific soil types are predetermined on the calcium carbide basis."

The paper is accompanied by an editorial note by F. E. H[ance], in which are included data from eight determinations of soil moisture compared with data for the same samples obtained by the oven-drying method at 102° C.

A method for obtaining a continuous measurement of soil moisture under field conditions, G. J. BOUYOUKOS and A. H. MICK. (Mich. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 3, p. 271).—Since the dielectric constant of plaster of paris is proportional to its moisture content, a measure of the conductivity of a standardized block of this material is a measure of soil moisture. Conductivity determinations are easily made by means of electrodes and a form of the Wheatstone bridge. "This device measures soil moisture ranging from the wilting point to the field capacity, or it is really a measure of the available water. It denotes the wilting point accurately. By knowing the wilting point and the available water, the total water content is thereby also known."

Determination of potassium by means of an aqueous solution of trisodium cobaltinitrite in the presence of nitric acid, L. V. WILCOX. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 9 (1937), No. 3, pp. 136-138).—An aqueous solution of trisodium cobaltinitrite replaces the familiar two-solution reagent. Nitric acid, rather than acetic acid, is used as the acidifying agent to maintain the nitrate-nitrite equilibrium and thereby prevent nitrite decomposition. The resulting precipitate is granular, heavy, and easily filtered and washed. The gravimetric and volumetric procedures for the determination of potassium by this new method are described. The normality of the oxidizing solution bears a stoichiometric relation to the potassium of the precipitate, and the equation for the reaction is shown. The absolute accuracy as well as the reproducibility appears to be within ± 0.05 mg. expressed as potassium.

Microscopical determination of potassium with naphthol yellow S, H. A. FREDIANI. (La. State Univ.). (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 8, pp. 447-449, figs. 2).—"Potassium may be determined qualitatively in the presence of ammonium by means of naphthol yellow S. Ammonium, cesium, lithium, magnesium, and sodium ions do not react with the reagent to form insoluble crystalline salts. Cupric, lead, rubidium, and silver ions form precipitates and may mask the microscopical test for potassium."

Determination of small amounts of potassium, D. S. BROWN, R. R. ROBINSON, and G. M. BROWNING. (W. Va. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 11, pp. 652-654).—The authors describe a simple and more rapid form of the cobaltinitrite method, ceric sulfate being substituted for potassium permanganate in the titration, while the precipitation is carried out at room temperature. It was found that the usual variations of room temperature do not affect the accuracy of the determination of from 0.6 to 1 mg. of potassium, but when the quantity experimentally deter-

mined was reduced to 0.2 mg. recoveries were too high at 0° C., close to the exact quantity at 20°, and somewhat low at from 25° to 30°.

Filtering before addition of platinic chloride in the analysis of fertilizers for potash, H. R. ALLEN. (Ky. Expt. Sta.). (*Jour. Assoc. Off. Agr. Chem.*, 22 (1939), No. 1, pp. 162-167).—Ignition in a silica dish gave a larger residue, less soluble in acid alcohol, than did ignition in platinum. Filtering the residue out before platinic chloride was added gave slightly less potash, and potash was sometimes found in the material removed. The amount of residue filtered from ignition in silica, if counted as potassium oxide, would increase the potash content erroneously in some instances. Residues obtained after ignition in platinum were small, particularly when hydrochloric acid was added when the ignited material was dissolved in the dish. Ignition in platinum, solution of the ignited salts in hydrochloric acid and water, and determination of potassium chloroplatinate by weighing the filter, crucible, and contents, leaching out, and weighing the crucible gave the most potassium oxide. One drop of tributyl citrate in the digestion prevented foaming.

The citrate solubility of dolomite of varying particle size, C. W. WHITTAKER, L. F. RADER, JR., and K. V. ZAHN. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 22 (1939), No. 1, pp. 180-189, figs. 2).—Experiments on an ammonium citrate solution adjusted to pH 7 as solvent for evaluating the solubility of dolomite as contained in physiologically neutral fertilizers indicated that this reagent is unsuitable for control work by reason of excessive variation in the results obtained with mixtures differing in age and composition. "It is felt that during the growing season the MgO is probably about equally available to plants in all cases in spite of the fact that its solubility in the neutral ammonium citrate varied widely. . . . No doubt real differences in the solubility existed and were measured with more or less accuracy by this reagent, but its extreme sensitivity to the age and composition of the mixture makes it unsuitable for use in the routine determination of the solubility of magnesium."

The authors are of the opinion that 2 percent citric acid, ammonium citrate solution of pH 4, and citrated ammonium nitrate solution should give more uniform results. The solubilities of the MgO in these solutions are much higher than in ammonium citrate solution of pH 7, and alterations in the state of combination of the magnesium in the fertilizer would, therefore, have less effect.

Decomposition of dolomitic limestone in soils when used as a neutralizing agent in complete fertilizers, P. R. DAWSON, E. F. SNYDER, W. R. LEIGHTY, and F. R. REID. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 22 (1939), No. 1, pp. 137-141).—This paper reports preliminary results of studies on the comparative decomposability of dolomitic limestone of different degrees of fineness when applied to soils as the neutralizing agent in non-acid-forming fertilizers. The experiments now in progress comprise pot trials in which the dolomitic materials are applied to the soil as constituents of a complete neutralized fertilizer and are allowed to react with the soil in the presence of a growing crop under conditions simulating those in the field. The comparative rates of decomposition of the dolomites are evaluated by the changes in pH, the residual carbonates, and the readily soluble magnesium in the soil of the fertilizer placement zone, as well as by the changes in magnesium content of the crop, after each of several successive treatments and crop periods.

Iron determination in presence of titanium, using zinc reduction, E. TRUOG and R. W. PEARSON. (Wis. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 11, pp. 631, 632, fig. 1).—After passage of the sample solution through a Jones reductor, the appearance of a violet color indicates the presence of 0.1 mg. or more of titanium. This may be selectively oxidized by

adding 50 cc. of distilled water containing the normal quantity of dissolved air. If the quantity of titanium is less than that which gives a violet color to the solution, keeping the volume of the solution down to from 200 to 250 cc. and stirring vigorously for 3 min. in a 400- or 600-cc. beaker will effect an aeration sufficient to oxidize the titanium, leaving the iron salts unaffected.

A dithizone method for measurement of small amounts of zinc, P. L. HIBBARD. (Univ. Calif.). (*Indus. and Engin. Chem., Analyt. Ed.*, 9 (1937), No. 3, pp. 127-131).—The zinc having been brought into solution by suitable means, this solution is made alkaline by ammonia, a chloroform solution of dithizone is added, and the mixture is shaken and let stand a minute to separate. If zinc is present it combines with the dithizone in chloroform and colors it red. The intensity of color is proportional to the amount of zinc, which may conveniently be from 0.001 to 0.020 mg. The amount of zinc may be also measured by a titration procedure, using approximately 0.001 N bromine in carbon tetrachloride.

Improved molybdenum blue reagents for determination of phosphorus and arsenic, J. A. SCHRICKE and P. R. DAWSON. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 22 (1939), No. 1, pp. 167-179, fig. 1).—Determinations of minute quantities of phosphates in soil extracts, plant material, etc., were found to be affected both by the buffer action of appreciable concentrations of salts and by the composition of the ceruleomolybdate reagent.

The ranges of concentration of sulfuric acid, molybdic oxide, and reduction over which color intensity remains practically constant were determined. The conditions for minimum interference of yellow tints, silica, and salt effects were shown to require the minimum reduction and molybdic oxide concentrations and the maximum sulfuric acid concentration compatible with uniform and complete color development. Modified molybdenum blue reagents meeting these requirements used in the proportion of 1 part per 100 parts of test solution have a sulfuric acid concentration of 36 N, reduction concentration of 0.04 N, and molybdic oxide concentration of 0.18 M and 0.32 M for phosphorus and arsenic, respectively. In composition they conform to $0.02 \text{ M Mo}_{10}\text{O}_{26}$ and $\text{Mo}_{17}\text{O}_{40}$ for phosphorus and arsenic, respectively. "Preparation of the reagents themselves requires little time and care, but on the other hand, temperature and time are important factors in actual color development up to the point where a final stable end point is reached. Great precision may be obtained by measuring the colors in a photoelectric colorimeter, as little as 1 γ or less equivalent of phosphorus being readable."

Quinaldine red in place of β -dinitrophenol as an indicator for preliminary adjustment of the pH of the test solution is recommended. Sulfurous acid is recommended instead of sodium bisulfite to prevent arsenic and nitrite interference in highly buffered and salt-containing solutions such as soil extracts.

An alternative method for phosphorus, specifying a sulfomolybdic acid reagent corresponding in concentration to the molybdenum blue reagent and methol as a reducing agent, is also described.

The use of a Taylor phosphate slide comparator for the determination of phosphates in soil extracts, T. C. LONGENECKER. (N. J. Expt. Stas.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 362-364, fig. 1).—Because of the limitations of the spot plate method, a search was made for a more reliable method, rapid enough to fit in with the remainder of the soil testing procedure. The Taylor phosphate slide comparator appeared to fulfill these requirements. The procedure was found to consume very little more time than the spot plate method, and the concentration of phosphorus could be determined to within 5 p. p. m.

The preparation of suitable reagent solutions is described, and manipulative detail is given.

Determination of phosphorus in fruits and fruit products, H. W. GERRITZ. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 22 (1939), No. 1, pp. 131-137, fig. 1).—The proposed method, found by the author to be more convenient and accurate than volumetric procedure and comparable to the official gravimetric method, consists essentially of the molybdenum blue phosphate determination. Minor modifications have been introduced to adapt Zinzadze's method more specifically to the use of the neutral wedge photometer and to the analysis of samples prepared by wet ashing.

Determination of arsenic, A. K. KLEIN and F. A. VORHES, JR. (U. S. D. A.). (*Jour. Assoc. Off. Agr. Chem.*, 22 (1939), No. 1, pp. 121-130).—Having separated the arsenic from organic matter, either by a solvent procedure or by wet oxidation, the authors reduced the arsenic to a trivalent form by means of potassium iodide and acid, formed and extracted arsenic xanthate by treatment of its solution with sodium ethyl xanthate in carbon tetrachloride and alcohol solution, washed out interfering substances dissolved by the carbon tetrachloride by means of concentrated hydrochloric acid containing stannous chloride, evaporated the carbon tetrachloride, oxidized the arsenic to the pentavalent state by adding bromine, developed the molybdenum blue color with the Zinzadze reagent (*U. S. R.*, 74, p. 585), and completed the determination by means of a neutral wedge photometer.

A rapid potentiometric method for determination of sulfate, B. E. CHRISTENSEN, H. WYMORE, and V. H. CHELDELIN. (Oreg. State Col.). (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 8, pp. 413, 414, figs. 5).—The authors found a change in the electrode potential at the equivalence point in the titration of sulfate solutions with barium chloride solutions when a trace of persulfate had been added. The break was neither large nor very sharp in purely aqueous solutions, but was more marked in the presence of from 25 to 60 percent of methanol. Ethanol and acetone also sharpened the end point indication, but the methanol gave the best result. It was found that the quantity of persulfate should be 1 mg. or less. When the sulfate concentration was less than 0.05 N the break was too slight to be used, and when the sulfate concentration was greater than 0.25 N the precipitate was too heavy for the best results. The end point occurred not at the stoichiometrical end point but at about 95 percent of complete precipitation. The titration should be performed in nearly neutral solution, since in acid or distinctly basic solutions the results were poor.

Dichlorofluorescein and potassium chromate as indicators in the argentometric estimation of salt in butter, K. G. WECKEL. (Univ. Wis.). (*Jour. Dairy Sci.*, 22 (1939), No. 3, pp. 163-168).—The results of a series of tests comparing dichlorofluorescein and potassium chromate as indicators in the routine analysis of butter showed that the mean of the titrations using the former was consistently and significantly less than for the latter. When a single salt solution prepared from recrystallized sodium chloride was titrated with silver nitrate, using first potassium chromate and then dichlorofluorescein, the latter results were in closer agreement with the calculated percentage of salt than the former.

Determination of sugars in plant materials, W. T. FORSEY, JR. (Fla. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 8, pp. 411, 412).—Using an alkaline solution of a specially purified potassium ferricyanide as oxidant, the author was able to determine glucose satisfactorily by measurement in a photoelectric colorimeter of the diminution of the intensity of the

yellow color of the ferricyanide solution. He finds that "precise results can be obtained with samples containing from 0.05 to 0.4 mg. of reducing sugars," in a rapid and simple procedure requiring but one standard solution.

A method of estimating the volatile products liberated from stored fruit, F. GERHARDT and B. D. BEZEL. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 7, pp. 493-503, fig. 1).—The authors established optimum conditions for the quantitative oxidation of acetaldehyde by excess of standard ceric sulfate solution in dilute sulfuric acid, the unused oxidant being titrated iodometrically with standard sodium thiosulfate. The reaction as used for this determination was empirical rather than stoichiometrical, the cerium equivalent of acetaldehyde having been 6.8. The acetaldehyde volatilized from stored fruit was found to be absorbed by sulfuric acid from an air stream of 10 l. per hour, the average acetaldehyde recovery being 97.2 percent.

A precise method for the determination of carotene in forage, D. W. BOLIN and A. M. KHALAPUR. (Idaho Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 8, pp. 417, 418).—The authors extracted the carotene with 95 percent alcohol and saponified fatty matter in this solvent. They then extracted the carotene and xanthophyll with petroleum spirit, and removed xanthophyll from the petroleum spirit solution with 85 percent methyl alcohol. This procedure is recommended on the ground that it avoids the formation of emulsions, permits the use of definite quantities of reagents, and gives more accurate results than do the customary procedures.

Improved method for estimating carotene in feeds, G. S. FRAPS and A. R. KEMMERER. (Tex. Expt. Sta.). (*Jour. Assoc. Off. Agr. Chem.*, 22 (1939), No. 1, pp. 190-194).—The authors found it possible to activate some samples of U. S. P. light magnesium oxide in a manner such that it will adsorb xanthophylls from solutions of carotene and xanthophyll but leave the carotene in solution. Other samples, however, did not yield an activated adsorbate showing this selective action, and the method given requires testing of each preparation on purified carotene solutions and on xanthophyll solution. Crude carotene solutions may be purified by magnesium hydroxide showing the correct selective adsorption and the remaining color read as that of pure carotene.

Departures from additivity among Lovibond red glasses in combination with Lovibond 35 yellow, G. W. HAUPT (*Oil & Soap*, 15 (1938), No. 11, pp. 282-287, figs. 4).—The author studied 2,700 Lovibond red glasses in groups of 1,000, 1,000, and 700, all three studies showing departures from additivity of such a magnitude as to be capable of introducing serious discrepancies in the grading of vegetable oils if such glasses were used without calibration. Both regular and erratic departures from additivity were observed.

Evaluation of washing compounds and compliance with bottle washing standards, C. R. ARNOLD and M. LEVINE. (Iowa State Col. et al.). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 18 (1938), No. 3, pp. 82-84).—The authors tested four commercial alkali bottle-washing preparations, comparing these with 1.5 percent sodium hydroxide solution at body temperature with *Staphylococcus aureus* as test organism and at 140° F. with the highly resistant *Bacillus metiens* as test organism. In these tests and in time tests also carried out the sodium hydroxide solution was definitely superior to any one of the four preparations compared with it.

Alpha cellulose from sugar cane bagasse and foliage, R. ARROYO. (P. R. Expt. Sta.). (In *The Puerto Rico Sugar Manual*. New Orleans: A. B. Gilmore, 1938, pp. 26, 27).—The process described entails grinding to between 10 and 20 mesh-particle size; steaming in a manner which removes dirt, together with much of the waxy matter and color; compressing and air-drying; immersion

overnight in 50 percent normal butyric acid containing about 2.5 percent of acetic acid, followed by 6 hr. heating in this reagent in reflux; washing; air-drying; heating with sodium hydroxide solution of 4° B.; bleaching in 7.5° bleaching powder solution; a second sodium hydroxide treatment in a solution of 15°; a second bleaching in 5° bleaching powder solution; immersion in 2 percent butyric acid overnight; washing out of the acid; and drying.

Cane bagasse yielded from 33 to 38 percent alpha-cellulose prepared in this way. Cane straw yielded from 25 to 28 per cent. The author considers that this product, from 92 to 95 percent alpha-cellulose and from 0.25 to 3 percent ash, should sell for no less than \$75 per ton.

Colloids in the sugar mill, H. P. KOETSCHAK (*Hawaiian Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 1, pp. 33-38).—Colloids, the removal of which may become necessary in sugar mill practice, are here grouped into three classes, the first consisting of colloids present in cane juice itself or derived from the cane stalk and designated "inherent colloids," a second group of "extraneous colloids" coming from any material which enters the mill other than cane stalk, and a third group of "process colloids" formed as a result of manufacturing procedure. In the first group are included pectin, together with pectic acid and its salts; pentosans; proteins; waxes; fats and fatty acids; polyphenols (coloring matters and tannins); and starch. In the second group, and including the most troublesome colloids met with in the sugar mill, are the organic and inorganic soil colloids. The process colloids mentioned are glucose decomposition products and sugar salts. The effects of these various colloids upon clarification, filtration, evaporation, and crystallization are discussed.

Preparing and processing apple juice, R. E. MARSHALL (*Mich. State Col.*). (*Mich. State Hort. Soc. Ann. Rpt.*, 67 (1937), pp. 42-48).—The author here briefly reviews the necessary equipment and the various steps in the process of preparing a clarified and filtered apple juice of high quality.

The utilization of surplus plums, W. V. CRUESS (*Univ. Calif.*). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 18 (1938), Nos. 3, pp. 72-74, 89, 91, figs. 2; 4, pp. 101-105, fig. 1).—The author suggests that plums may be crushed in an ordinary apple crusher and packed in barrels or enamel lined cans and stored indefinitely at a freezing temperature for use in jams and jellies. Cull plums of sound quality will give as good jams and butters as higher priced fruit. Jam pulp may also be made from cull plums. Other products considered are canned sauce, jelly, jelly juice, candy and candy base, beverage sirup, preserves, dehydrated plums, canned and bottled beverage, and canned fruit.

Fermentation of orange juice as affected by the addition of nitrogenous nutrients, A. J. NOLTE (*U. S. D. A.*). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 16 (1937), No. 12, pp. 360-362, fig. 1).—The fermentation of sweetened orange juice was stimulated by the addition of such nutrient materials as ammonium carbonate and distillers' malt. The most favorable range of concentration of ammonium carbonate has been found to be between 0.9 and 1 gm. per liter, that of distillers' malt to be 0.5 percent when the starter consists of a malt infusion. Because of the inconvenience of preparing distillers' malt, ammonium carbonate is considered more suitable. The aroma and taste of the new wine from must to which ammonium carbonate had been added as a yeast nutrient was better than that of the wine from control batches to which no nutrient salt had been added. Of eight strains of yeast studied, that designated No. 2338, *Saccharomyces ellipsoideus* Hansen I, was found to be the most suitable from the standpoint of its vigor and of flavor produced in the finished wine. The wines had a pleasing bouquet, but none had an odor and taste resembling that of orange juice.

AGRICULTURAL METEOROLOGY

Certain ecological factors and the cotton plant, B. JOHNSON and C. H. WADLEIGH (*Arkansas Sta. Bul. 376 (1939), pp. 51, figs. 47*).—The weather factors (monthly rainfall, rainy days per month, monthly mean maximum temperature, monthly mean and cumulated monthly mean minimum temperatures, and a combination of monthly rainfall and monthly mean maximum temperature) in relation to the cotton plant as expressed by yield of lint were studied (1919–35) for the six eastern counties of Arkansas, either for March to October, inclusive, or in some cases for the months of greatest growth of the plant. In general, rainfall in April, May, and July showed high correlations with yields, but in June there was less covariability. The best yields were associated with rainfall at or near the minimum reported for these months, provided these small precipitations were properly distributed. Increasingly high monthly mean maximum temperatures in May, June, and August were associated with increased yields, while such increases in July (above 93° F.) and in September (above 86°) were associated with decreasing yields. The relations of monthly mean and cumulated monthly mean minimum temperatures below the annual mean for several months to yield of cotton resulted in the largest standard errors of estimate, and perhaps had less direct relation to yield than the other factors considered. As to the relation of the combination of rainfall and monthly mean maximum temperature to yield, the importance of April, May, and July in this association is made more evident. July mean maximum temperature showed a very high correlation in this relationship, but June rainfall and monthly mean maximum temperature had relatively low correlation coefficients in this association, as they did in the other relationships studied in June.

Graphs of the regression surfaces of the joint relation of certain weather factors and location of county to yield are presented, the relationships varying from county to county and in some cases the slopes of the curves being markedly different. In general, however, the trend in the individual counties was similar to that of the entire area studied. However, the importance of the trends in the subregions (counties) of highest yields may greatly affect the mean yield from the total area, and this condition is discussed and the effects in the several subregions are presented.

Climate and agriculture in California, M. K. BENNETT (*Econ. Geog., 15 (1939), No. 2, pp. 155–164, figs. 9*).—This is a general discussion of the relations of climate to agriculture in California, considered under climatic diversity, characteristics of climate, concentration and character of agriculture in the State, and the agricultural prospect.

Weather phenomena of the Colorado Rockies, R. L. IVES (*Jour. Franklin Inst., 226 (1938), No. 6, pp. 691–755, figs. 20*).—Field observations indicated that the major portion of Colorado's moisture is brought in by the winter cyclones. Winter winds redistribute the snow, and Chinook winds remove a portion of it from the mountains and adjacent plains. Summer storms of three types tend to redistribute the moisture derived from the melting snow. The regional and local or valley storms, of almost daily occurrence, are topographically confined convection phenomena, which daily transfer small amounts of moisture across divides. Cyclones tend to augment the violence of both other types, while anticyclones inhibit the regional storms but have a negligible effect on the local storms. Numerous barometric, electrical, and optical phenomena of great interest but minor climatic importance are described briefly. Theories explaining the various phenomena are presented, and possible applications of

the results of this and further studies of mountain weather conditions are suggested. Sixteen references are included.

Precipitation and water supply in the Sierra Nevada, California, E. ANTEVS (*Bul. Amer. Met. Soc.*, 20 (1939), No. 3, pp. 89-91).—Since the normal precipitation and water supply and the extremes of the dry and wet periods are of great importance for future developments in the Sierra Nevada region, the author examines and discusses the published records and interpretations of facts so far as available since the area was first settled by white man about 1850. The records include fluctuations of Eagle, Tahoe, and Mono lakes in relation to changes in the relative amounts of snow and rain and the behavior of glaciers, and the factors involved in tree growth on the Truckee.

Floods of Ohio and Mississippi Rivers, January-February 1937 (U. S. Geol. Survey, Water-Supply Paper 838 (1938), pp. XII+746, pls. 25, figs. 97).—The main part of this paper is a report by N. C. Grover, presenting records of stage and discharge for the period including the floods at about 250 measurement stations, records of storage in many reservoirs, a summary of peak discharges with comparative data for other floods at about 470 measurement points, and tables showing crest stages along an aggregate length of stream channel for 5,000 miles. The report also includes basic information in regard to the weather associated with the floods, results of detailed studies of the rainfall and run-off, analyses of the volume of floodwaters in the surface channel systems during the progress of the floods, and much related information.

Following the main flood report is a brief report by G. R. Mansfield on "flood deposits of the Ohio River, January-February 1937, a study of sedimentation," in which mechanical analyses of deposits are grouped into 12 location categories, and geological evidence as to the present and preceding floods is considered. The possibilities of the data presented as a basis for flood control measures are pointed out.

The determination of evaporation from land and water surfaces, C. W. THORNTHWAITTE and B. HOLZMAN (*U. S. Mo. Weather Rev.*, 67 (1939), No. 1, pp. 4-11, pls. 2, figs. 5).—The importance and complexity of the problem of determining rate and amount of evaporation from land and water surfaces or transpiration from vegetation is stressed. In an effort to supply much-needed information, a method for determining evaporation from either land or water areas is presented in this preliminary report and its practicability is said to be demonstrated. It is also hoped that with proper instrument installation it will become possible to determine transpiration rates and moisture requirements of various field crops and forest trees, the effectiveness of various moisture-conserving practices, and the relative importance of evaporation and transpiration in the hydrologic cycle.

Evaporation studies.—III, Ten years of evaporation at Wooster as measured with black and white atmometers, J. D. WILSON (*Ohio Sta. Bimo. Bul.* 197 (1939), pp. 11-25).—Continuing this series (E. S. R., 79, p. 584), a State-wide survey was begun in Ohio in 1928 and data have been accumulated as daily readings from black and white atmometers from May 1 to September 30 each year since. The average (10-yr.) monthly values from the black and white atmometers and a standard evaporation pan were in the same order of magnitude for the 5-mo. period, July values being the largest, followed in decreasing order to September. The effect of radiant energy was responsible for ± 29 percent of the total water loss from the black atmometer for the 50-mo. period. Evaporation was above the average for the 10-yr. period in 1930, 1932, 1933, 1934, and 1936, and droughts of varying severity occurred in these years, as well as in 1928 and 1929. The drought of 1930 was most severe. Evapora-

tion-rainfall ratio values for each of the 50 mo. indicated that rainfall exceeded evaporation in only 13 of them, whereas evaporation was in excess by at least 50 percent in 24 of the 50 mo. and was at least twice as great in 18 of them. Twelve droughts were recorded for the period 1923-37. Those falling in May and June were particularly injurious to oats and early garden crops, those in July and early August reduced corn yields, and those in late August and September were least important, affecting chiefly the seeding of wheat. Correlations and variations between pan and atmometer records are discussed in detail. Indications were that the pan is more influenced by variations in the radiant energy and temperature factors than is the atmometer. The monthly variations for the pan losses corresponded most closely to those for sunshine duration, followed in turn by those for temperature, relative humidity, and wind. The average value of an hour of sunshine in terms of water evaporated from a black atmometer was largest in June, followed by July, August, September, and May, in that order.

Meteorological phenomena affecting low temperatures on experimental peat bog, J. H. NEAL (Minn. Expt. Sta.). (*Agr. Engin.*, 19 1938), No. 6, pp. 273-277, figs. 2).—For some years it has been known that frosts may occur on peat bogs in any month of the year. Some of the factors involved are air drainage, depth of subdrainage, depth and compactness of the peat, dryness of the surface, and vegetation. The usual weather conditions found on the day preceding a frost were a low maximum temperature and a dropping to 55° F. or less by 10 p. m., a high barometric pressure (usually rising), a clear sky, and a northerly wind of a low velocity. Weather conditions on the day of the frost, except for the early morning, had no bearing on frost occurrence. In case of wind changed from northerly to southerly, or the sky from clear to cloudy shortly after midnight, frosts were usually warded off, though conditions the evening before may have indicated a frost. Although each particular bog will have certain local conditions affecting temperature, it is deemed very likely that the probability of a frost can be predicted along the lines discussed with a fair degree of accuracy after these local conditions are known.

Second note on the logarithmic law of wind structure near the ground, H. U. SVERDRUP (*Quart. Jour. Roy. Met. Soc.* [London], 65 (1939), No. 278, pp. 57-60, figs. 2).—The author critically reviews his own work and that of others and presents formulas and graphs, concluding that very near the boundary surface stable and unstable conditions influence the wind profile and the eddy convectivity according to the same law, that certain observations can be interpreted as showing that the roughness parameter of the surface is a well-defined physical quantity, and that the influence of stability can be expressed by means of a nondimensional constant. He believes that the wind profile at greater distances from the boundary surface is represented better by a power than by a logarithmic law.

Protecting the sugar industry from losses due to hurricanes, G. E. Howe (In *The Puerto Rico Sugar Manual*. New Orleans: A. B. Gilmore, 1938, pp. 14-23, figs. 16).—The stated object of this article is to present in a simple manner information on buildings for use by the sugar industry. Puerto Rico being located in the hurricane region, the destructive effects of great windstorms have an important bearing on building design in this and similar areas. The author therefore presents data relating to wind velocities and pressure and the principles on which buildings should be constructed to resist hurricanes.

Sulphur dioxide content of air at Boyce Thompson Institute, II, C. SETTESTROM (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 2, pp. 183-187).—In view of the importance of SO₂ as an atmospheric contaminant, and because

of the widespread disagreement as to the harmful effects on plants of low concentrations of the gas, a continuous record was kept from November 1, 1936, to November 1, 1938, with minor interruptions. The results for the first year have been reported previously¹ with descriptions of the methods used, sources of SO₂, and the condition of the vegetation. The present paper summarizes the data for the second year. For the periods reported the average concentration including zero readings was 0.035 p. p. m., and the maximum recorded was 0.53 p. p. m. SO₂ was present in concentrations of 0.01 p. p. m., and above, 60.6 percent of the time. Meteorological records indicated that prevailing wind directions were much the same for both periods.

The sunspot period, H. H. CLAYTON (*Smithson. Misc. Collect.*, 98 (1939), No. 2, pp. [1]-18, pl. 1, figs. 12).—Since the sunspot period is becoming important in numerous fields of scientific activity, much significance attaches to the forecasting of the time and intensity of the maxima and minima. The present paper attempts to show that the smoothed plus and minus annual departures from normal pressure observed in the earth's atmosphere are displaced in position in unison with variations in intensity of sunspot maxima, and that the annual sunspot numbers may be resolved into a number of regular periods of constant length and amplitude which, when combined, make the regular sunspot period and permit forecasting, with reasonable accuracy, the dates of maxima and minima of sunspots and the intensity of the maxima.

Variability in solar radiation [trans. title], F. STEINHAUSER (*Met. Ztschr. [Braunschweig]*, 55 (1938), No. 12, pp. 442-448, fig. 1).—The author investigated the irregular changes in radiation intensity such as occur in the monthly or yearly average radiation values observed over long periods of time, and such as are due to fluctuations in atmospheric penetrability from day to day when deviations of the individual values from the average annual radiation become evident. The scattering of the individual values over the annual curve decreases markedly with the altitude of the point of observations, as shown by the 6-yr. records presented.

Measurements of radiation in bright sunlight [trans. title], F. SAUERER (*Met. Ztschr. [Braunschweig]*, 55 (1938), No. 12, pp. 435-442, figs. 5).—In sunlight, measurements of the spatial distribution of light were made in fog and the radiation balance was determined for horizontal and vertical stone surfaces. Furthermore, the radiation balance was compared over different surfaces, principally stone and snow, in fog and in sunny weather. Very high positive radiation balance values were found over dirty ice. On bright days the radiation balances of snow surfaces after midday may exceed those over stone, since the total radiation of stone can increase strongly as a result of the raising of surface temperature. Reflection measurements with and without color filters were made by the use of photoelements.

Investigations of the distribution of light in a beech stand [trans. title], E. TRAPP (*Bioklim. Beibl. Met. Ztschr.*, 5 (1938), No. 4, pp. 153-158, figs. 5).—The light distribution in a 0.25 ha. beech stand was determined by photoelectric elements. In addition to the usual determinations some cartographic surveys were made under different weather conditions and at different times of day. The average degree of light in the stand fell under complete foliation to ± 5 percent that in the open. A map showing the locations of the trees and their crowns (with the areas thinly and thickly foliated) is presented. The vertical light distribution was also investigated.

Utilizing heat from the sun, C. G. ABBOT (*Smithson. Misc. Collect.*, 98 (1939), No. 5, pp. [1]-11, pls. 4, fig. 1).—The author discusses the quantity of solar

¹ Contrib. Boyce Thompson Inst., 9 (1938), No. 3, pp. 171-178, fig. 1.

energy available, intermittance and storage of solar power, water distilling and cooking by solar heating, recent commercial products a boon to solar devices, mechanism for following the sun, domestic water heaters, solar cookers, solar water distilling, the solar flash boiler for power, flash-boiler devices, automatic regulation of flow of boiler water, efficiency of solar flash boiler, competition of solar power against coal, oil, and water power, early experiments with solar power (1910), storage of solar heat or power, and the commercial use and cost of solar heating.

Monthly Weather Review, [January–February 1939] (*U. S. Mo. Weather Rev.*, 67 (1939), Nos. 1, pp. 38, pls. 21, figs. 6; 2, pp. 39–60, pls. 14, figs. 4).—In addition to the usual detailed summaries of climatological data, solar and aerological observations, observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and bibliographical and other information, these numbers contain the article noted on page 333 and the following contributions:

No. 1.—A Brief List of Works on Meteorology, compiled by R. T. Zoch (pp. 1–3); Valley-Head Cloud Windows, by R. L. Ives (pp. 11, 12); Duststorms of 1938 in the United States, by R. J. Martin (pp. 12–15); and Weather of 1938 in the United States, by J. P. Kohler (pp. 16, 17).

No. 2.—An Observation of Variable Water-Vapor Content in Rapidly-Moving Air Masses, by A. Adel and C. O. Lampland (p. 39); and Unusual Fluctuations in the Dew-Point Along the Southern California Coast, by D. Blake (pp. 39–41).

Climatological data for the United States by sections, [January–December 1938] (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 25 (1938), Nos. 1–12, [about 200 pp., 3 pls., 3 figs. each]).—These numbers contain the usual brief summaries and detailed tabular statements of climatological data for each State.

[Meteorological records at the Georgia Coastal Plain Station] (*Georgia Coastal Plain Sta. Bul.* 29 (1938), pp. 12, 13).—The following tabulated data are included: Rainfall in inches by months and years, 1923–37; dates on which first and last killing frosts occurred and the number of growing days at Tifton, 1923–37; and temperature by months, 1937.

[Meteorological work by the Nebraska Station] (*Nebraska Sta. Cir.* 60 (1939), pp. 9–13, figs. 2).—A historical sketch is given of the achievements of the station with respect to weather records, studies, and publications. A map shows the distribution of average precipitation in Nebraska and a graph illustrates the average rainfall for the State as a whole from 1876 to 1938.

SOILS—FERTILIZERS

[Soil investigations by the Western Washington Experiment Station] (*Western Washington Sta. Rpt.* 1938, pp. 39–43).—This report notes work on soil reaction studies, by K. Baur; on fertilizer placement; adaptability and fertility studies on the Nisqually, Felida, and Lauren series; on fertilizers for freezing peas, by Baur; and on maintenance of organic matter in western Washington soils.

A tool for the rapid sampling of soils, F. L. DAVIS. (*La. Expt. Sta.*). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 3, p. 270, fig. 1).—The sampling tool was made from an 18-in. piece of plumber's brass tubing with a wooden handle fitted into one end. A slot for facilitating the removal of the soil was cut into one side of the tube with a thin emery wheel and a hacksaw blade. The bottom end of the tube can be kept sharpened with a large-size cork borer sharpener or mill file.

[Soil Survey Reports, 1932-35 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1932, No. 33, pp. 48, pls. 2, figs. 2, maps 2; 1933, No. 22, pp. 45, figs. 2, map 1; 1934, No. 14, pp. 56, figs. 3, map 1; 1935, No. 4, pp. 60, figs. 2, map 1*).—These surveys were made in cooperation with the Alabama Department of Agriculture and Industries and the Texas and Wyoming Experiment Stations. That for 1932, No. 33, covers Sheridan County, Wyo., J. Thorp et al.; 1933, No. 22, Colbert County, Ala., L. G. Brackeen and A. L. Gray; 1934, No. 14, Hunt County, Tex., E. H. Templin and R. M. Marshall; and 1935, No. 4, Hale County, Ala., M. J. Edwards et al.

Desert subsoil temperatures, W. V. TURNAGE (*Soil Sci.*, 47 (1939), No. 3, pp. 195-199, figs. 2).—The construction, calibration, use, and performance in use of simple copper- and constantan-wire thermocouples for determining soil temperatures are briefly described.

Soil temperatures at 3-, 6-, and 12-ft. depths from March 1937 to May 1938 at Tucson, Ariz., are shown, together with comparative thermometer and thermocouple records at the 6-ft. depth for the same period. The minimum temperature periods at the three depths occurred just before and during the spring growing season when leaf and stem growth of plants was rather active. The maximum temperature periods came during the summer rainy season when stem growth was at a maximum. At these depths the temperature at no time fell below the minimum for root growth of desert plants. Neither did the temperature rise as high as the optimum for root growth of certain desert plants having known optima. The range of temperature from the summer of 1937 until the summer of 1938 at 3 ft. was 25° F., at 6 ft. 15°, and at 12 ft. only 7°.

Nebraska soils and their management (*Nebraska Sta. Cir.* 60 (1939), pp. 14-21, figs. 4).—This article presents a brief popular historical summary of the soil work of the station since 1887.

The forest floor of the chaparral in San Gabriel Mountains, Calif., J. KITTREDGE, JR. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 7, pp. 521-535, fig. 1).—The author studied the amount of the forest floor material and its water relations in the Fern and Bell Canyons in southern California. The Fern Canyon showed an average of 15 metric tons of forest floor material per acre, almost three times the average quantity found in the Bell Canyon.

"The mean volume weights for individual types vary from less than 0.1 to 0.36. In Fern Canyon there is a well-defined differentiation between the types or group with high means in which manzanita, chamiso, or bigcone-spruce . . . predominate and those with low means in which the oaks predominate.

"Field moisture capacities vary less within types than the other measures. Three groups within each canyon show a significant difference in the means, although the difference between 157 percent in one canyon and 150 percent in the other is not significant. In general, the manzanita, *Ceanothus*, and chamiso are associated with low field moisture capacities of the floor and oak and bigcone-spruce with high.

"The depth of water retained by the forest floor represents an integration of amount, volume weight, and field moisture capacity of the materials, and gives an indication of the role of the forest floor in intercepting rainfall. Like its component elements, it varies within types to such an extent that the small differences between the means of types are rarely significant. The groups of types, however, are distinct, a low group in Bell Canyon retaining 0.06 in., a high group 0.12 in.; and in Fern Canyon, a low group, 0.19, and a high group, 0.26 in. These amounts, less the actual moisture content at the beginning of rain, would be held subject to evaporation from the forest floor and would not contribute to soil moisture or to surface run-off."

The annual accumulation and creep of litter and other surface materials in the chaparral of the San Gabriel Mountains, Calif., J. KITTREDGE, JR. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 7, pp. 537-541).—The average annual accumulation of organic material in the chaparral communities of diverse composition, age, and location rarely varied beyond the amounts of from 0.2 to 1.4 metric tons per acre, with a general average of 0.6. The ratio of total forest floor to the annual accumulation increased with age of the vegetation from about 8 in the 18-year-old chaparral of Bell Canyon to over 26 in the more than 50-year-old types of Fern Canyon. Leaf material constituted from 37 to 67 percent of the annual accumulation and amounted to about 0.25 metric ton per acre on an average. Two exceptions, with percentages of 0.7 and 5.6, may be mentioned for types to which chamiso gave character. Sufficient creep of loose surface material took place annually to override a 2-in. barrier on 18 percent of the area of Fern Canyon and on 16 percent of the area of Bell Canyon.

Some moisture relationships of soils from burned and unburned longleaf pine forests, F. HEYWARD (*Soil Sci.*, 47 (1939), No. 4, pp. 313-327, pls. 2, fig. 1).—Field moisture percentage was determined throughout the year in four paired burned and unburned areas. Normal moisture capacity and wilting percentage were also determined in undisturbed soil columns, together with the water-holding capacity of sifted soil.

All determinations of field moisture percentage being grouped, for the 0- to 2-in. depth in 26 of 28 determinations the soil from the unburned timber stands was more moist, 12 of these differences being statistically significant; for the 4- to 6-in. depth, soils from unburned stands were more moist in 20 of 28 determinations, of which 11 were significant; and for the 8- to 10-in. depth, soils from unburned stands were more moist in 22 of 28 determinations, of which 11 were significant. The differences in percentage were small as absolute values, but in relative values soils from the unburned areas were as much as 52 percent more moist for the 0- to 2-in. depth than for the corresponding soil depth on burned areas. Differences between moisture retention as measured by wilting percentage and normal moisture capacity obtained for undisturbed soil columns from the 0- to 3-in. depth were neither large nor consistent. The soils protected from fire showed a slightly higher retention of water as determined for sifted soil from the 0- to 3-in. depth. Since the differences in water retention were not sufficiently large to explain the differences found between field moisture percentages, it is concluded that the differences in field moisture were caused by some factor other than the nature of the soil itself.

Some changes in the soil during natural succession of vegetation after abandonment in western Nebraska, B. I. JUDD and M. D. WELDON. (Nebr. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 3, pp. 217-228, figs. 4).—The authors studied cultivated land, native grassland, and land abandoned for various periods of time in Kimball County, Nebr., to ascertain the changes occurring in the soil during revegetation.

The rate of infiltration of water in the field was considerably greater under wheat stubble than under native vegetation. It was relatively low after 1 yr. of abandonment, but after several years became approximately equal to that of the wheat stubble land. Bare areas in the abandoned land generally had a low infiltration rate. The rate of percolation of water through a 6-in. column of topsoil showed about the same relationships as the infiltration rate. Percolation in the soil from the native grassland and the bare areas of the abandoned land was much slower than in that from the stubble field and the abandoned areas under vegetative cover.

The volume weight and the state of aggregation of the soils were very closely correlated. The volume weight and the percentage of large aggregates (larger than 0.5 mm.) were highest in the soils having the lowest infiltration and percolation rates, and were generally lowest in the soils permitting the fastest infiltration and percolation.

The organic matter and nitrogen content of the soil of cultivated and abandoned fields tended to be lower than in the native grasslands, but the difference was not statistically significant for the number of samples taken. Under the native grasses 7.3 percent of the soil organic matter in the surface 6 in. and 2.2 percent of that in the second 6 in. was found to consist of plant roots. Under cultivation or abandonment, the percentage of root material was much smaller. The root content of the soil of the cultivated fields, determined shortly after wheat harvest, was found to be from one-fourth to one-third of that under native grassland vegetation. After several years of abandonment, the root content of the soil was greater than in cultivated fields and was approximately half of that under native grasses.

The effect of 1936 flood deposits on Vermont farm lands, D. E. DUNKLEE and A. R. MINGLEY (*Vermont Sta. Bul. 445 (1939), pp. 16, pls. 8*).—This bulletin reports briefly upon a survey of the extent and nature of the 1936 flood damage and describes the reclamation measures found most effective.

Rivers carrying from 7 to 19 in. of rainfall left deposits consisting mostly of silt and sand on more than 4,000 acres while more than 300 acres of cropland were washed downstream. Deposits were from 1 in. to 6 ft. deep, more than one-third of them being too deep to be plowed under.

Most of the deposits lacked plant food, except lime, and certain acid deposits lacked lime also. Manure (10–20 tons per acre) or complete commercial fertilizer (200–400 lb. per acre, double strength) produced good crops, whereas those on unfertilized areas were stunted. Small subsequent annual applications were found to be preferable to those made once in a rotation.

Early spring seeding, especially of legumes, was found vitally necessary. Surface sowing before machinery could be used worked well with sweetclover. Sweetclover produces a large tonnage, improves soil condition, and seed is cheap. Reed canary grass is suggested for use on sedge and cattail swales. Bromegrass was the best sod-forming, deposit-resisting crop on dry silts. A mixture of oats, red and alsike clovers, alfalfa, timothy, and bromegrass did well on shallow neutral deposits. Corn, rye, buckwheat, barley, and oats succeeded on deep acid deposits when heavily manured. Shallow acid deposits, when plowed under, could be planted to the same crop that formerly succeeded.

“Ordinary seeding practice is apt to be inapplicable under these unusual conditions. To check blowing sand is more important than to increase its fertility; hence deposits should be plowed if the old soil can be reached, since harrowing encourages sand blowing. Fall plowing is obviously inadvisable on river bottoms. The use of a corrugated roller tends to check driven sand. Quackgrass and weeds keep sand from blowing from unreclaimed areas onto adjacent lands. Planting willows along river banks tends to inhibit further loss of cropland.”

Principles of gully erosion in the Piedmont of South Carolina, H. A. IRELAND, C. F. S. SHARPE, and D. H. EARGLE. (Coop. S. C. Expt. Sta.). (*U. S. Dept. Agr., Tech. Bul. 633 (1939), pp. 143, figs. 96*).—This bulletin covers a general study of conditions which make the southern Piedmont particularly susceptible to gully, and an investigation of the causes, mechanics, and rate of gully cutting in 12 representative gullies, largely untreated, in South Carolina, together with less detailed study of a much larger number. The authors find

4 distinct stages in the development of the deep caving gully characteristic of the southern Piedmont. "In stage 1, the channel-cutting stage, the gully works downward through the A and B horizons. Cutting in this stage is relatively slow, and this is the time at which protective measures can best be undertaken. Stage 2 begins when the gully penetrates the base of the B horizon and begins cutting in the weak parent material. This stage, characterized by the headward migration of an overfall and plunge pool and by rapid caving of the walls and deepening of the channel, is much the most violent stage of gully growth and is the least favorable for the successful application of control measures. Caving and slumping of the walls and heads alternate with periodic clearing out of the caved material from the gully channel. Additional substages in the gully's growth may occur in the form of periods of headward progression of successive waterfalls or knickpoints, marking renewed channel cutting and deepening of the gully. Stage 2 ends when erosion is retarded because the channel reaches a graded condition under the control of some local base level. Stage 3 is a period of adjustment to the graded channel. Slopes of the gully walls are reduced by weathering, slope-wash, and mass movement; plants are able to get a foothold on the lowered slopes, and vegetation gradually brings about a healing of the gully. Stage 4 is a period of stabilization and is characterized by the slow development and accumulation of new topsoil over the old scarred surface. Rejuvenated cutting brought about by lowering of the base level or an increase in the amount or rate of run-off can at any time cause stage 3 or 4 to revert to stage 2."

Major climatic factors in gully erosion in the Spartanburg area are the intense cold-front rains and tropical hurricanes of late summer and early fall. Deep weathering of the igneous and metamorphic rocks of the Piedmont prepares the way for rapid erosion. Past and present land use, and periods of land abandonment, in particular, have been causes of sheet erosion and gullyng.

Major climatic factors in gully erosion in the Spartanburg area are the intense cold-front rains and tropical hurricanes of late summer and early fall. Deep weathering of the igneous and metamorphic rocks of the Piedmont prepares the way for rapid erosion. Past and present land use, and periods of land abandonment, in particular, have been causes of sheet erosion and gullyng.

Strip cropping in southwestern Pennsylvania, D. H. WALTER. (Coop. U. S. D. A.). (*Pennsylvania Sta., Jour. Ser. Paper 783 (1937), pp. 12*).—This report is based upon 19 farms where strip cropping has been practiced for from 5 to 20 yr. Of these, 16 had all rotation land strip cropped. Strip cropping was started by 16 of the 19 farmers primarily to control erosion. Nine farmers claimed they started the practice without any outside knowledge or influence, 5 had the idea from neighbors, and 3 from reading. Slope was thought by the operators to be the most important factor in determining whether a field should be strip cropped, and degree of slope and convenience in size of fields were the two important factors determining width of strips. The average width of 96 strips on the farms surveyed was 139 ft., and the average slope 16.4 percent. These strips were found to average 4 percent off contour. Only 1 farmer used any type of instrument to lay out strips. There was a tendency to have less clean tilled crops on the steeper slopes.

In general, the operators thought less power and time were required in working fields under their system of strip cropping. Yields were estimated by operators to be higher now than 10 or 15 yr. ago, primarily because of lime, manure, and erosion control. Gully control was reported by the farm operators to be the most important accomplishment of strip cropping. Sod waterways were found on 9 farms, but were fully adequate to control erosion on only 3.

Base exchange in soils.—I, A critical examination of the methods of finding base-exchange capacity of soils, A. N. PURI and H. L. UPPAL (*Soil Sci*, 47 (1939), No. 3, pp. 245-253, fig. 1).—From the results of a critical review of methods of finding the base-exchange capacity of soils, the authors conclude that different methods refer to different points on the titration curves of soils and, as such, are arbitrary and empirical. The only satisfactory method of defining the base-exchange properties of soils is through their titration curves, the determination of which is as easy as is the finding of base-exchange capacity by any of the well-known methods.

The determination of redox potentials of soils, N. J. VOLK. (Ala. Expt Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 344-351).—All chemical preservatives tested, when they effectively inhibited bacterial action in soils, also altered the Eh of the soil to such an extent that the results were no longer comparable. Cooling the soils to just above the freezing point was found to be a very effective preservative method, however.

Oxidation of reduced compounds in the soil was prevented by the use of water saturated with nitrogen and by performing analytical operations in an atmosphere of nitrogen. The Eh-pH relationship, even within close range of the initial pH, was found to vary from 58 to 101 mv. for different soils. The Eh-pH relationship was, therefore, determined for each soil studied and correction in Eh made accordingly for differences in pH. Potential drift was found to be due to previous treatment of the blank electrodes and not to the agar bridge. Smooth straight wire platinum electrodes 2 cm. in length were found superior to foil, since roots clinging to the foil electrode caused misleading results. Details of the analytical procedure finally adopted are given. Results agreeing within 5 mv. by this method are considered satisfactory. Eh values of from 15 to 20 soils per hour can be determined by using a battery of 30 aspirators involving 30 glass electrodes and 120 blank electrodes.

A method for controlling the pH of nutrient solutions in sterile sand cultures, H. A. WILSON and L. A. RICHARDS. (Iowa Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 358-362, figs. 3).—The authors describe a set-up designed to provide continuous sterile irrigation with buffered nutrient solutions for a study of the influence of pH upon the nitrogen-fixing power of certain rhizobia. The apparatus produced a rate of flow of about 18 l. per pot per day under the operating conditions specified.

Phosphate buffering was satisfactory at pH 7 or above but could not be used at lower values because of the steep slope of the phosphate titration curve below pH 5.4. For the range from pH 4 to 7, buffering with potassium hydrogen phthalate was found more suitable.

Comparative study of the colloids of a Cecil and a Susquehanna soil profile, W. P. KELLEY, A. O. WOODFORD, W. H. DORE and S. M. BROWN. (Univ. Calif.). (*Soil Sci.*, 47 (1939), No. 3, pp. 175-193, figs. 4).—On the basis of chemical composition, dehydration investigations, optical properties, and X-ray analysis, it was concluded that the colloidal material of the Cecil profile has essentially the same composition throughout the profile and consists primarily of halloysite or kaolinite. Even the granite-gneiss, only slightly altered, found at a depth of 24 ft. shows the presence of kaolinitic clay. This was taken to indicate that under the climatic conditions of Alabama, a kaolinitic type of clay is formed at a comparatively early stage in the weathering of granite-gneiss.

The colloid of the Susquehanna profile is predominantly kaolinitic in the A and B horizons and beldellitic or montmorillonitic in the deeper horizons. The almost white layer found at about 11 ft. in depth is primarily montmorillonite.

Mineralizable nitrogen in some Hawaiian soils, E. T. FUKUNAGA and L. A. DEAN. (Hawaii Expt. Sta.). (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 1, pp. 17-22, figs. 2).—The moisture equivalent was shown to be a satisfactory moisture content at which to maintain soils when they are incubated for the purpose of determining mineralizable nitrogen. There appear to be two phases of nitrogen release when soils are incubated—an initial rapid phase (from 3 to 4 weeks), followed by a phase of slow release. The initial phase appears to be associated with the microbiological decomposition of predominantly nitrogenous compounds. A very significant relationship was found between the mineralizable nitrogen and the uptake of nitrogen by *Panicum grass (P. purpurascens)* grown in pots.

Is sunlight a factor in nitrogen transformation in soil? B. N. SINGH and K. M. NAIR (*Soil Sci.*, 47 (1939), No. 4, pp. 285-291).—Various nitrogenous substances were tested in exposed and covered sterilized and unsterilized substrates. The experimental technic concerned in the protection of treatments from light was designed to avoid large thermal variations generally resulting from the blackening of the surfaces of containers.

"The accumulation of nitrite was due to both photochemical and biological reactions. The oxidation of nitrite to nitrate was exclusively due to biological agency. The conclusion reached is that biological reactions are largely responsible for the processes of ammonification and nitrification in soil, though nitrite is formed also as a result of photochemical action."

The influence of cropping on the nitrogen-fixing powers of soil, J. E. GREAVES and A. F. BRACKEN. (Utah Expt. Sta.). (*Soil Sci.* 47 (1939), No. 3, pp. 201-206).—When soils from wheatland and adjacent virgin land from Juab County were inoculated into a synthetic medium, the gains in nitrogen from the cropped soils were greater than those from the virgin soils in all 3-ft. sections used; in Cache County, fixation was greater in the cropped first foot but reversed in the second foot. The nitrogen gains made by the Cache County soils were considerably greater than those of Juab soils. "This is probably due to two factors; namely, the Cache soils contain a larger quantity of carbonaceous materials than the Juab soils; almost all of the Cache soils carry a rich *Azotobacter* flora, whereas these organisms are generally absent in the Juab soils."

When alfalfa soil was inoculated into the same medium, the fixation was about twice that observed when virgin or wheatland soil was used. The increase was observed in the first, second, and third-foot sections of the soil "and is the result of either a direct or an indirect action of the legume upon the nonsymbiotic nitrogen fixers." The addition of ground alfalfa, ground pea vines, and ground straw to Nephi dry-farm soil increased the nitrogen-fixing power during the first 2 yr. to approximately the same extent. The influence of the treatment with alfalfa persisted longer, however, than did the influence of the pea vines or straw. All the plant residues caused greater increases in the nitrogen in the soil than could be accounted for by the added nitrogen. The greatest gains in soil nitrogen were caused by the addition of alfalfa. Some of the added carbonaceous material still remained in the soil after 11 yr.

Thermophilic decomposition of plant residues in composts by pure and mixed cultures of microorganisms, S. A. WAXSMAN and T. C. CORDON. (N. J. Expt. Stas.). (*Soil Sci.*, 47 (1939), No. 3, pp. 217-225, pl. 1).—Mixtures of 80 percent straw and 20 percent alfalfa were found to give composts without requiring the addition of any mineral salts. Cereal straw supplemented with mineral salts and with calcium carbonate gave an excellent compost in from 21 to 35 days when kept at about 50° C. The presence of CaCO₃ was essential

for the rapid decomposition of plant materials as a whole, and especially of cellulose by the active thermophilic fungi.

A thermophilic population obtained from an active compost brought about greater decomposition at higher temperatures than did a mesophilic population obtained from soil. No single pure culture could give as extensive and as rapid decomposition as the total population of a thermophilic compost. Among the thermophilic organisms active in the decomposition of plant materials in composts, certain fungi and actinomycetes were found highly significant. One thermophilic fungus was found to compare favorably with the total thermophilic population.

Excellent growth of the edible mushroom *Psalliota campestris* was obtained on composts of plant residues. This organism was found to derive its nutrients primarily from the lignin and its transformation products and from the proteins in the compost.

The effect of degree of base saturation of soils upon the fixation of phosphate and potassium and the availability of phosphorus, G. M. GILLIGAN (*Delaware Sta. Bul. 215 (1938), pp. 20, figs. 8*).—Three soils (one highly organic) were deprived of their exchangeable bases by electrodialysis, and series of these soils with increasing calcium saturation were prepared for the purpose of determining the effect of degree of Ca saturation upon the sorption of phosphorus and potassium.

Phosphate sorption was influenced by both degree of calcium saturation and pH. Appreciable fixation took place in the hydrogen soils. This type of sorption is attributed to the formation of difficultly soluble Fe and Al phosphates. A decrease in sorption in the lower Ca soils and slightly acid range was observed with one organic and one inorganic soil. Sorption in the Ca soils is looked upon as a function of the exchange complex and pH and influenced by the nature of the exchangeable ions involved. At high Ca levels (in the presence of high Ca-ion concentrations, high pH, and CaCO_3) the high sorption values observed are attributed in large part to the precipitation of insoluble calcium phosphate. The mechanism of phosphate sorption by the organic soil is considered to be less complicated than that taking place in inorganic soils. The sorption curve resembles the precipitation curve obtained when a mixture of an organic acid in a H_3PO_4 is titrated with $\text{Ca}(\text{OH})_2$.

Sorption of potassium in a nonexchangeable form increased with increasing degree of Ca saturation in the inorganic soils. The organic soil failed to fix potassium in a nonexchangeable form.

"The results indicate that from a practical standpoint it is advisable to maintain the soils investigated at a calcium level sufficiently high to avoid the formation of insoluble Fe and Al phosphates yet somewhat below complete saturation where insoluble calcium phosphate is precipitated. Demobilization of potassium would be anticipated as a result of overliming."

Decomposition of dolomitic limestone in soils when used as a neutralizing agent in complete fertilizers: Studies on Dunbar very fine sandy loam, Ruston sandy loam, Norfolk fine sandy loam, and Portsmouth fine sandy loam, E. R. COLLINS and F. R. SPEER. (N. C. Expt. Sta.). (*Jour. Assoc. Off. Agr. Chem.*, 22 (1939), No. 1, pp. 142-147, fig. 1).—The purpose of this study was to determine the rate of decomposition of the dolomitic limestone as evaluated by reaction change in the soil and by the determination of residual carbonates after a crop of cotton had been grown on it for from 65 to 75 days. Magnesium determinations were made on a few plant samples to indicate any change in the concentration of magnesium in the plant due to the decomposition of the dolomitic limestone during the growing season.

Neutralization curves for the humic acids of peat soils, B. D. WILSON and E. V. STAKER ([*New York*] *Cornell Sta. Mem.* 219 (1939), pp. 19, figs. 6).—Humic acids variously extracted from peat soils were titrated by means of a glass electrode and barium hydroxide, the nature of the acidity being indicated by neutralization curves.

The neutralization curves were found to resemble those characteristic of weak acids. Some of the humic acids showed a break in the curves, others not. Whether or not a break appeared seemed to depend more on the method employed in preparing the humic acids than on the organic material used in making the extract. "The absence of more than one break in the neutralization curves for acids which are generally considered to be polybasic may have been occasioned by the presence of mixed groups of acids, the dissociation constants of a particular acid or group of acids being indistinguishable because of the reaction effects of other acids." The character of the neutralization curves is shown to be closely related to the cation-exchange capacity and to the initial reaction of the humic acids.

The availability, to crop plants, of different forms of selenium in the soil, O. E. OLESON and A. L. MOXON. (S. Dak. Expt. Sta.). (*Soil Sci.*, 47 (1939), No. 4, pp. 305-311, figs. 2).—The authors analyze six soils from seleniferous farms for various important constituents, including total and water-soluble sulfur and total, water-soluble, acid-soluble, and organic selenium. Ten plantings were made on the soils in the greenhouse, and the plants were analyzed for selenium to determine the availability of the selenium in the six soils to various plants. The availability of the selenium in soils appears to be dependent upon the amount of water-soluble selenium, which in turn seems to be correlated with the amount of organic selenium in the soil. The total sulfur content and the water-soluble content of a soil appear to be of little or no significance in determining the availability of selenium to plants in a naturally seleniferous soil.

The selenium cycle and the forms of selenium in soils are discussed briefly. Toxicity studies with arsenic in eighty California soils, A. S. CRAFTS and R. S. ROSENFELS. (Coop. U. S. D. A.). (*Hilgardia* [*California Sta.*], 12 (1939), No. 3, pp. 177-200, figs. 3).—Arsenic toxicity in soils was correlated with texture, being greatest in sandy soils and least in soils of high clay content. All red soils rendered much of the arsenic unavailable, however.

Arsenic sterilization on coarse, gritty soils in California requires a dosage of 2 lb. As_2O_3 per square rod. Loams, silt loams, and those clay loams developed directly from acid igneous rocks or highly weathered require from 4 to 6 lb. per square rod. Clays and adobe clays and some clay loams demand applications of from 8 to 12 lb. per square rod. Red soils or recent alluvial soils from sedimentary rocks require approximately twice as much arsenic for a given type.

It was shown that light annual applications of soluble arsenic or use of dry arsenic trioxide with the addition of about 10 percent sodium chlorate may be less wasteful on soils that render much arsenic unavailable. Heavy leaching tends to reduce the concentration of available arsenic in the soil.

Arsenic fixation in relation to the sterilization of soils with sodium arsenite, R. S. ROSENFELS and A. S. CRAFTS. (Coop. U. S. D. A.). (*Hilgardia* [*California Sta.*], 12 (1939), No. 3, pp. 201-229, figs. 6).—In addition to further observations similar to those noted from the preceding paper, the authors found that decreasing the moisture content of a soil below field capacity has no effect upon toxicity. This is attributed to the fact that, within the range of sublethal applications, the concentration of arsenic remains about the same

in some soils and in others decreases. Moisture content at field capacity is not an important factor in arsenic toxicity.

Curves of concentration, C , against application, A , may be constructed from two experimental determinations of concentration by the use of the equation $\log C = -1.5 \log (F - a) + \log K$, in which C equals parts per million of soluble As_2O_3 , a equals milligram of As_2O_3 fixed by 1 kg. dry soil, and F and K are constants. "Curves relating the percentage yield in the greenhouse tests to the concentration of soluble arsenic, plotted from the curves of C against A , were much more alike than the standard toxicity curves relating percentage yield to application of arsenic on the basis of dry soil—a fact suggesting that arsenic toxicity can be largely explained in terms of fixation."

Toxicity studies with sodium chlorate in eighty California soils, A. S. CRAFTS (*Hilgardia [California Sta.]*, 12 (1939), No. 3, pp. 231-247, figs. 3) — Repeated cropping of chlorate-treated soils resulted in continued loss of toxicity. Toxicity to the first crop was highest in Stockton adobe clay, second in Fresno sandy loam, third in Columbia fine sandy loam, and lowest in Yolo clay loam. By the seventh crop toxicities had shifted so that Fresno sandy loam stood highest, Columbia fine sandy loam second, Yolo clay loam third, and Stockton adobe clay lowest. Although fertility largely governs the initial toxicity of chlorate in soils, "some other factor controls the change in toxicity with time and cropping." The general relation of toxicity to fertility was confirmed. In nearly every case, soils deviating markedly from the expected results proved to have come from arid regions and consequently to be high in total salts.

Yield tests and land valuation, W. G. MURRAY, A. J. ENGLEHORN, and R. A. GRIFFIN (*Iowa Sta. Res. Bul.* 252 (1939), pp. 49-76, figs. 2).—Corn yields on various areas in Tama and Story Counties were determined, and the degrees of correlation between yield and depth of soil and between yield and slope were studied. In both counties the correlation with depth was significant for depths of 8 in. or less. Slope was less significant as directly considered, but slope and depth showed a negative correlation. Yields of oats as well as of corn were used in some of the work.

The adaptability of rapid chemical tests for use in determining the nutrient needs of South Carolina soils, F. MOSER. (S. C. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 3, pp. 188-199).—The author compared the Universal soil testing system developed by Morgan of the Connecticut [New Haven] Experiment Station (E. S. R., 77, p. 302), the Purdue, the Thornton, Conner, and Fraser (E. S. R., 72, p. 303), the Bray test (E. S. R., 62, p. 13), and two commercial testing systems, with reference to their use in determining the requirements of South Carolina soils. All readings of the tests were made comparable by using a 5-cc. aliquot of the soil extract for reading the results of each test in parts per million. Each of the tests was previously standardized by checking against known concentrations of phosphorus and potassium.

"The data show that the Universal, Simplex, and LaMott testing methods may be used for estimating the phosphorus needs of soil, but the Purdue and Bray tests are not very satisfactory for this purpose for South Carolina soils. The results also show that all the methods tested show about the same amount of available potassium on soil having approximately the same milligram equivalent of replaceable potassium. The 1937 yields show that on Orangeburg fine sandy loam a good response for potash fertilizer was obtained on plats where the rapid tests indicated a low availability." The Cecil sandy clay loam gave significant yield increases for potash fertilization, a medium content of available potassium or doubtful response having been indicated by rapid tests; whereas a negative correlation was found between yields and the rapid tests on Cecil sandy loam.

Handbook of fertilizers: Their sources, make-up, effects, and use, A. F. GUSTAFSON (*New York: Orange Judd Pub. Co., 1939, 3. ed., pp. 172, pl. 1, figs. 25*).—This book "is an attempt to supply accurate, up-to-date information as to the source and make-up of commercial fertilizers. Special stress is laid on the effects of fertilizers on soils and crops in the hope of aiding the user in making a wise choice for his individual soil and cropping conditions. . . . Farmers are urged to consider the interrelationship between crops and the effects of the residues from fertilizers used for one crop on those which follow." The chapter headings are: Requirements for plant growth, nitrogenous fertilizer materials, phosphatic fertilizer materials, potash fertilizer materials, effect of fertilizers on crops and soils, factory-mixed fertilizers, home-mixing of fertilizers, purchase and use of fertilizers, liming in relation to fertilizer practice, and organic matter in relation to fertilizer practice and use.

Inspection of agricultural lime products for the season of 1938, H. D. HASKINS (*Massachusetts Sta. Control Ser. Bul. 97 (1938), pp. 9*).—This twenty-seventh inspection report gives the composition of the various products which have been sold in Massachusetts during the year. Of the ground limestone products, the mechanical analysis is also given.

AGRICULTURAL BOTANY

Plant physiology in the women's colleges, D. DAY (*Plant Physiol., 14 (1939), No. 1, pp. 179-181*).—This is a summary of a report on the teaching of plant physiology, with its implications to agriculture and democracy in America.

Aging in plants, W. CROCKER (*In Problems of Ageing: Biological and Medical Aspects*, edited by E. V. COWDEY (*Baltimore: Williams & Wilkins Co., 1939, pp. 1-31, figs. 5*)).—This is a critical summary of present knowledge, with nearly three pages of references.

Estimation of protoplasmic permeability from plasmolytic tests, G. W. SCARF (*Plant Physiol., 14 (1939), No. 1, pp. 129-143*).—"This paper includes a discussion of the principles of estimating protoplasmic permeability plasmolytically, the derivation of comprehensive formulas for use in estimating the protoplasmic permeability of cylindrical and spherical cells, and some notes on technic."

Time and temperature of protoplasmic coagulation, H. T. and R. T. NORTON. (*Univ. Wyo.*). (*Plant Physiol., 14 (1939), No. 1, pp. 175, 176*).—At 43.5° C. and above a decided increase in protoplasmic consistency was induced—interpreted as coagulation—in cells of corn, oat, rye, and wheat coleoptiles, and in *Spirogyra* and *Zygnema* a lower temperature effected a decided increase in protoplasmic firmness. The time element in coagulation at 43.5° and at 47.5° suggested the coleoptile-cell protoplasm of wheat, rye, and oats to be more sensitive to high temperature than that of corn.

The relation between structure and function of the phloem, A. S. CRAFTS. (*Univ. Calif.*). (*Amer. Jour. Bot., 26 (1939), No. 3, pp. 172-177, figs. 5*).—Careful microscopical and physiological studies lead to the assumption that a high state of permeability exists in mature sieve tubes. Tests with 58 species from mosses and helps to the most highly specialized angiosperms suggest that this permeable state may characterize these elements in all plants. The common occurrence of phloem exudation and permeable sieve tubes supports the pressure-flow theory as to the mechanism for translocation of organic solutes in plants.

Observations on the membranes of epidermal cells of the *Avena* coleoptile, W. K. FARR and W. A. SISSON (*Contrib. Boyce Thompson Inst., 10 (1939), No. 2, pp. 127-137, figs. 6*).—The microscopic and X-ray diffraction studies re-

ported are concerned with the membranes of these cells at a period during the process of cell enlargement, and are believed to indicate the following: The cellulose component is in the form of microscopically visible ellipsoid particles of native crystalline cellulose arranged in transverse bands. During cell elongation these bands are distributed at increasing intervals along the membrane without altering their orientation with respect to the long axis of the cell. The plastic state of the noncellulosic component of the membrane is maintained during cell elongation. Although it has been supposed previously that the cellulose is in a state of tension, this is now rendered highly improbable because it is present in the form of discontinuous bands. It is shown that during the process of cell elongation, the tension is exerted not only on the cellulose but also on the more plastic noncellulosic, continuous phase of the membrane.

A new type of embryogeny in the conifers, P. L. COOK. (Univ. Ill.). (*Amer. Jour. Bot.*, 26 (1939), No. 3, pp. 138-143, figs. 13).—The early embryogeny of *Juniperus communis* is described and illustrated, disclosing a type unique in the Coniferales and, so far as known, approximated elsewhere only in the Gnetales.

The embryogeny of *Sequoia sempervirens* with a comparison of the Sequoias, J. T. BUCHHOLZ. (Univ. Ill.). (*Amer. Jour. Bot.*, 26 (1939), No. 4, pp. 248-257, figs. 23).—The described and illustrated features of the gametophytes and embryogeny of *S. sempervirens* are compared with those of *S. gigantea*, *Sciadopitys*, *Athrotaxis*, and other conifers. It is concluded that the two Sequoias belong to different genera.

Flower buds and phylogeny of dicotyledons, A. GUNDERSEN (*Bul. Torrey Bot. Club*, 66 (1939), No. 5, pp. 287-295, figs. 7).—For many characters, such as sympetaly, zygomorphy, and epigyny, the ontogeny of flowers is said to confirm accepted views of phylogeny, but while flowers with parietal placentation are similar in the bud and adult forms, those with axile placentation usually have a beginning of parietal placentation in the bud. Taxonomic relations are suggested.

Relations between tissue organization and vein distribution in dicotyledon leaves, R. B. WYLIE (*Amer. Jour. Bot.*, 26 (1939), No. 4, pp. 219-225, figs. 10).—An analysis of leaf structures for 3 groups of dicotyledons (22 herbaceous and 24 woody plants from Iowa and 20 Pacific coast woody plants) indicated a significant correlation between mesophyll organization and vein distribution. The results suggested that problems of transfer from cell to cell restrict mesophyll proximity to vascular supply, and that all tissue arrangements furthering or retarding conduction between living cells become factors in vein separation.

The influence of growth substances on the development of wound tissue in orchard trees [trans. title], E. JAKŠ and H. HEKNEBOVÁ (*Gartenbauwissenschaft*, 13 (1939), No. 1, pp. 83-93, figs. 3).—In tests with cherry, plum, apple, and pear trees, the authors treated artificial and natural wounds at the beginning of each experiment with a paste containing "Belvitan" or 1 percent heteroauxin paste. As compared with the untreated controls, the treatment in all cases induced an accelerated wound-tissue regeneration. Callus formation occurred not only at the edges but also in independent centers over the entire wound surface. With treatment of two wounds 2-5 cm. distant from each other on the same branch, the callus was always better on the lower of the two wounds. Of the two pastes used, Belvitan gave better results than heteroauxin (perhaps the concentration of indoleacetic acid was too high). The results are deemed sufficient to warrant recommending the practical application of growth substance preparations for every kind of wound healing on orchard trees.

Auxin distribution in fruits and its significance in fruit development, F. G. GUSTAFSON (*Amer. Jour. Bot.*, 26 (1939), No. 4, pp. 189-194).—The growth substance (auxin) content of ovules and developing seeds is believed to be much greater than of other parts of fruits, and it is considered possible that they produce auxin. Auxin other than that added artificially was found in fruits produced by treating the flower with phenylacetic acid. The probable role of auxin in the growth of parthenocarpic and nonparthenocarpic fruits is discussed. Pepper, tomato, agave, cucumber, squash varieties, yucca, and *Pittosporum whipplei* were used in these studies.

The cause of natural parthenocarpy, F. G. GUSTAFSON (*Amer. Jour. Bot.*, 26 (1939), No. 3, pp. 135-138).—The auxin content in ovaries of flower buds from varieties of oranges, lemons, and grapes producing fruits parthenogenetically was found to be higher than in ovaries from corresponding varieties not producing fruit in this way.

Evidence for the presence in certain ether extracts of substances partially masking the activity of auxin, R. H. GOODWIN (*Amer. Jour. Bot.*, 26 (1939), No. 3, pp. 130-135).—Determinations of the diffusion coefficients of auxin in ether extracts of corn meal and *Vicia faba* shoots failed to agree with the theoretical values for auxin *a* or *b*. The evidence suggested that this discrepancy was due to the presence in the extracts of substances partially masking the biological effects of the auxin on *Avena* coleoptiles. At least some of these substances are said to be ether- and water-soluble, with molecular weights larger than for auxin. Partial purification of auxin extracts may be made by diffusion methods. In determining the activity of unknown extracts, the possible presence of such masking substances should be considered, for if present in appreciable amounts the actual amount of auxin in an extract may be greater than that detected by the *Avena* test.

Leaf-epinasty tests with chemical vapors, F. E. DENNY (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 2, pp. 191-195).—Of 77 volatile chemicals not previously tested for ability to induce epinasty of potato leaves, only ethyl bromide, ethyl iodide, and propyl chloride gave positive results. The epinasty-inducing volatile product from various organs of plants cannot be any of these 3 alkyl halides nor acetonitrile since mixtures of these with air, when passed through a tube immersed in a freezing mixture of CO₂-snow and alcohol, gave negative tests for epinasty, while volatile products from plants were not condensed by the freezing mixture and the uncondensed gas which issued from the tube retained its effectiveness. Tests of the other volatile chemicals shown to cause epinasty (ethylene, propylene, acetylene, butylene, and CO) showed that the only one behaving like the effective volatile constituent from plant tissue in being absorbed by the Hg(NO₃)₂ reagent and released again without loss of epinasty-inducing power is ethylene. It is believed that the evidence indicates the effective constituent from plant tissue to be ethylene and not any of the other epinasty-inducing volatile chemicals tested.

Synthesis of β -(2-chloroethyl)- α -D-glucoside by potato tubers treated with ethylene chlorohydrin, L. P. MILLER (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 2, pp. 139-141).—"The acetylation of preparations of the chlorine-containing β -glucoside formed by potato tubers from absorbed ethylene chlorohydrin yielded β -(2-chloroethyl)- α -D-glucoside tetraacetate. The glucoside formed by the tubers is thus β -(2-chloroethyl)- α -D-glucoside and is identical with the glucoside formed by gladiolus corms treated with ethylene chlorohydrin."

Carbon dioxide storage.—XIII, Relationship of oxygen to carbon dioxide in breaking dormancy of potato tubers, N. C. THORNTON (*Contrib. Boyce*

Thompson Inst., 10 (1939), No. 2, pp. 201-204).—In continuation of this series* (E. S. R., 80, p. 428), the results obtained are deemed to indicate that elimination of dormancy in freshly harvested tubers by CO₂ treatment is not due to development of a condition of temporary anaerobiosis during treatment. Instead, CO₂ was most effective in breaking dormancy when it acted in the presence of 20 percent or more of O₂, and this treatment was more effective than complete anaerobiosis brought about by N treatment. The optimum concentrations of CO₂ were 10-60 percent in combination with 20-80 percent of O₂, which, with 5-7 days' treatment, caused the emergence of sprouts from 50 percent of one-eye pieces in soil within 17-30 days, as compared to 44-78 days for the controls.

The synthesis and destruction of vitamin B₁ by *Phycomyces*, J. BONNER and E. R. BUCHMAN (*Natl. Acad. Sci. Proc.*, 25 (1939), No. 4, pp. 164-171).—Vitamin B₁ was found to be synthesized by *P. blakesleeianus* from a mixture of vitamin pyrimidine and vitamin thiazole, and subsequently to be broken down by the mycelium with destruction of thiazole and liberation of free pyrimidine. Presumably, the thiazole portion is attacked only when combined in the form of vitamin. The evidence is believed to indicate that the first step in the in vivo degradation of the thiamin molecule involves an opening of the quarternary thiazole ring adjacent to the 2-position.

Vitamin B₆, a growth substance for excised tomato roots, W. J. ROBBINS and M. B. SCHMIDT (*Natl. Acad. Sci. Proc.*, 25 (1939), No. 1, pp. 1-3).—Studies here reported appear to indicate that the tomato root depends on the top not only for carbohydrate and thiamin (E. S. R., 80, p. 26), but also for vitamin B₆. The parasitic relation of the root to the shoot is thus more complex than hitherto supposed. In indicating the importance of vitamin B₆ for the growth of plants, it is suggested that this growth substance may prove to be as generally significant for living organisms as thiamin.

Further experiments on excised tomato roots, W. J. ROBBINS and M. B. SCHMIDT (*Amer. Jour. Bot.*, 26 (1939), No. 3, pp. 149-159, figs. 6).—In these studies (see also above) brown sugar proved to be more beneficial to growth than pure cane sugar in a solution of sugar, minerals, and thiamin, growth decreasing with reduction in the proportion present. Its ash was not responsible for the observed benefit. Crystalline vitamin B₆ was beneficial, but nicotinic acid, nicotamide, and amino acids—added to the solution of pure sugar, minerals, and thiamin—were not. Vitamin B₆ increased the growth when added to solutions of sugar, minerals, and thiamin in which the proportion of brown sugar was reduced. The beneficial effect of the brown sugar is believed to be due largely to its content of this vitamin. Hooks and curls are reported as developing in roots grown in solutions containing vitamin B₆, and these observations are interpreted to indicate the existence of a growth substance necessary for cell elongation in roots. Evidence is presented for an unknown growth substance in samples of maltose.

Growth behavior of one-millimeter excised root tips, G. C. GALLIGAR (*Plant Physiol.*, 14 (1939), No. 1, pp. 163-169, fig. 1).—Using a modified Pfeffer formula with dextrose and peptone added, no regularity of growth was found in excised root tips (principally sunflower and dent and sweet corn) with an original length of 1 mm., but the daily elongation rate (first 10 days) was much slower than that of root tips cut at 10 mm. Within the first 10 days sunflower and corn surpassed sweet corn in elongation rate, while cotton and Gradus and Burpee Extra Early peas grew scarcely at all. Corn tended to develop a short root with abundance of laterals, while sweet corn had the

* *Amer. Jour. Bot.*, 24 (1937), No. 10, p. 734.

reverse tendency. Vascular tissue proved unnecessary for growth of excised root tips. In sunflower, 1-mm. tips achieved greater growth than 10-mm. tips, and corn root tips were less able to accumulate dry weight when cut at 1 than at 10 mm. There are 13 references.

Translocation of carbohydrates in the sugar beet, O. A. LEONARD. (Iowa Expt. Sta.). (*Plant Physiol.*, 14 (1939), No. 1, pp. 55-74, figs. 8).—Fructose was found to increase in the leaf blades with progress of the season, a low level being associated with rapid and a higher level with slow growth and maturity. Fructose, glucose, and sucrose all exhibited marked diurnal variations within the blades, those of the first two together usually being twice those of sucrose. At times dextrin also showed marked diurnal variations in the blades and is an important secondary product of photosynthesis. In mature leaves in darkness the sugars continued to move into the petioles until the blades were depleted, and they evidently move out of the blade mesophyll into the veins in a polar direction. Polarization appears to be a property of the border parenchyma of the blades. In detached leaves in the sun, sugars moved out of the blade mesophyll and accumulated more or less evenly throughout the midribs and petioles. Here, as in darkness, there was no tendency for accumulation in one section of the petiole more than in another. While polarity prevented sugars from the phloem moving back into the blade mesophyll, no such polarity existed between the phloem and parenchyma of the petioles. During daylight sugar passed out of the phloem and accumulated in the surrounding cells, while at night the reverse occurred. Etiolated leaves contained considerably more glucose than fructose, and practically all the sugar present in the leaves is said to have arisen from sucrose. The results of feeding tests through the cut surfaces of petioles indicated that the various sugars are readily transformed into other forms. Fructose was converted into glucose and into dextrin, but there was also some conversion of glucose into fructose, and leaves fed sucrose contained no more sucrose than those fed either glucose or fructose. A bibliography of 22 entries is included.

Transpiration and the absorption of mineral salts, K. E. WRIGHT. (R. I. Expt. Sta.). (*Plant Physiol.*, 14 (1939), No. 1, pp. 171-174).—"The effect of transpiration upon the absorption of mineral ions was determined by analyzing culture solutions in which bean plants had been growing under conditions of high and low transpiration. The contributing effects of the metabolism of the plants upon mineral absorption were offset by (1) selecting plants with the same transpiring power when in the same environment; (2) analyzing the residual culture solutions of the same plants under conditions of high and low transpiration; and (3) devising an experimental procedure attempting to make transpiration the only variable. Analytical results indicate that an increase in the rate of transpiration is associated with a corresponding increase in the absorption of certain ions [P, Ca, NO₃, and K considered]." There are 13 references.

Effect of bordeaux mixture and its various elements on transpiration, J. G. HORSFALL and A. L. HARRISON. (N. Y. State Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 6, pp. 423-443, figs. 4).—The transpiration of bean and tomato plants in the greenhouse was measured daily by autotranspirators, calculated on the basis of leaf area, and expressed as transpiration ratios. High temperatures on the spray dates and the presence of water favored bordeaux transpiration, while high temperature afterwards failed to affect it. Copper insolubilized at \pm pH 7 had little effect on, both acid and alkaline materials accelerated, and oil reduced transpiration. A tentative explanation of the results is that the alkalinity of bordeaux saponifies the cuticle and decreases its resistance to water loss. Desiccation of cut shoots may be used to measure the

cuticular effects of sprays. Increasing the spray load accelerated the desiccation of cut plants, but generally decreased the transpiration from potted plants, presumably because more water is saved by stomatal plugging than is lost through the cuticle. Transpiration from potted plants represents the summation of cuticular and stomatal effects. The balance among various factors determines the magnitude of bordeaux transpiration. Where cuticles are thick and hard, as in the field, it is possible that the effect on the cuticle may at times be so slight as to be overbalanced by the factors for reduced water loss. There are 25 literature references.

Influence of light on the length of the conidia in certain species of *Fusarium*, L. L. HARTER. (U. S. D. A.). (*Amer. Jour. Bot.*, 26 (1939), No. 4, pp. 234-243).—The effects of sunlight and artificial irradiation on the length of 3-septate conidia were studied for *F. coerulesum*, *F. martii* pisi, and *F. bulbigenum* batatas grown on various media, the conidia being considerably longer in cultures grown in the light. Cultures held in darkness for the first 2 days and then irradiated for the rest of the growth period produced spores about equal in length to those exposed to light from the start. However, if a culture was incubated in darkness for the first 4 days after inoculation, the results were about the same as if it were kept in the dark during the entire incubation period. On the other hand, if the culture was irradiated for the first 4 days and then shifted to darkness, the results were about the same as if it had been grown in the light for the whole period. Sporodochia and pionnotes were more copious in the light, but vegetative growth was most abundant in the dark. The differences in spore length in cultures grown in light and darkness under otherwise identical conditions were much greater than those used for separating certain species. The maximum number of macroconidia occurred in the light, while microconidia predominated in the dark. Cultures incubated in the light usually gave more sporodochia and pionnotes and produced larger and more numerous macroconidia than those grown in the dark.

Statistically significant differences occurred when different individuals measured conidia from the same microscopic preparation. Such variations in measurements among different workers cannot be left out of consideration.

Response of lettuce seedlings to 7600A radiation, L. H. FLINT and C. F. MORELAND. (La. State Univ.). (*Amer. Jour. Bot.*, 26 (1939), No. 4, pp. 231-233, figs. 2).—"Radiation at 7,600 a. u. stunted the growth of lettuce seedlings. The effect was not associated with assimilation nor with temperature. Radiation at 8,500 a. u. and at 8,500 a. u. had no stunting effect. Radiation at 7,600 a. u. incited no phototropic response in lettuce seedlings."

Activation of cinnamic acid by ultra-violet light and the physiological activity of its emanations, P. W. ZIMMERMAN and A. E. HITCHCOCK (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 3, pp. 197-200, fig. 1).—"Commercial cinnamic acid is a relatively inactive compound for inducing curvatures but it can be activated by ultraviolet light. The *cis* form results from irradiation, and is the active form. When applied to plants as water solution or lanolin preparations this compound induces responses similar to other growth substances reported in earlier publications. In addition, the irradiated cinnamic acid induces epinastic responses of plants similar to ethylene gas when the crystals are set under a bell jar with the plants."

Movement of radiophosphorus in bean seedlings, O. BIDDULPH. (Wash. State Col.). (*Science*, 89 (1939), No. 2313, pp. 393, 394).—Using Red Mexican beans, the preliminary results reported indicate that phosphorus may be absorbed by the apparently uninjured roots of P-deficient plants and transported

at a rate exceeding 10 cm./hr. Movement in the aerial parts apparently depended on the transpiration stream, with "excretion" of P into the xylem only after considerable accumulation in the living cells of the root.

The introduction of agar-agar into bacteriology, A. P. HITCHENS and M. C. LEIKIND (*Jour. Bact.*, 37 (1939), No. 5, pp. 485-493, fig. 1).—A historical account (21 references), ascribing this important technical advance to Frau Fannie Hesse.

Growth factors for bacteria.—VII, Nutrient requirements of certain butyl-alcohol-producing bacteria, L. E. MCDANIEL, D. W. WOOLLEY, and W. H. PETERSON. (Wis. Expt. Sta.). (*Jour. Bact.*, 37 (1939), No. 3, pp. 259-268, figs. 2).—Continuing this series of studies (E. S. R., 78, p. 766), accessory growth substances for *Clostridium butylicum* and *C. acetobutylicum* were found in liver, yeast, malt sprouts, yellow corn, wheat bran, and a commercial vitamin preparation, and are discussed, with methods.

Role of nitrogen in fungous thermogenesis, J. O. GASKILL and J. C. GILMAN. (Iowa Expt. Sta.). (*Plant Physiol.*, 14 (1939), No. 1, pp. 31-53, figs. 12).—Asparagine, NH_4Cl , $\text{NH}_4\text{H}_2\text{PO}_4$, $(\text{NH}_4)_2\text{SO}_4$, and $\text{Ca}(\text{NO}_3)_2$, each greatly stimulated both thermogenesis and dry weight loss when added to the substrate in cultures of *Aspergillus flavus*, *A. terreus*, and *Penicillium oxalicum*, while with *Rhizopus tritici* all nitrogen forms tested increased thermogenesis markedly, except the nitrate, which distinctly inhibited it. Only asparagine increased dry-weight loss of *R. tritici*, all the other compounds exhibiting a depressing influence, with the nitrate most effective in this respect. Asparagine proved most generally suitable to the four fungi, both as to thermogenesis and dry-weight loss. The highest temperature recorded was for the two *Aspergilli*, each supplied with asparagine, viz, 49.25° C. or over 21° above the controls. The greatest loss in dry weight was 16.95 percent in *A. terreus* plus asparagine as compared with 3.54 percent loss in the minus nitrogen controls. Nitrogen additions of 0.01-0.1 gm. per 100 gm. of dry cob meal generally resulted in progressive increases in thermogenesis for *A. flavus*, while greater additions (0.2-1.6 gm.) usually gave results similar to those for the 0.1-gm. addition. Progressive increases in dry-weight loss in *A. flavus* followed the larger additions of asparagine, $\text{NH}_4\text{H}_2\text{PO}_4$, and $\text{Ca}(\text{NO}_3)_2$, respectively, up to 1.2 and 1.6 gm. N per 100 gm. of dry cob meal. The other three fungi differed considerably in response to varying amounts of these compounds. There are 18 references.

The heavy metal nutrition of fungi, J. W. FOSTER. (N. J. Expt. Stas.). (*Bot. Rev.*, 5 (1939), No. 4, pp. 207-239).—Discussing the subject matter of this review (152 references) under the concept of chemical stimulation and the influence of specific elements (Zn, Fe, Mn, Cu, etc.) in the nutrition of fungi, it is concluded that there can be no doubt that the need for trace amounts of various heavy metals is a phenomenon widespread among fungi. This appears especially true for the filamentous fungi, for which these elements must be considered indispensable. These fungi are considered ideally suited for trace element investigations because of their ease of cultivation and the large amounts of cell substance synthesized. The importance of an appreciation of the extreme sensitivity of fungi to traces of heavy metals, the fragmentary state of our knowledge, and the practical obscurity of the mechanism of action of metals are points that are stressed.

Experimental methods for the study of the role of copper, manganese, and zinc in the nutrition of higher plants, P. R. SROUT and D. I. ARNON. (Univ. Calif.). (*Amer. Jour. Bot.*, 26 (1939), No. 3, pp. 144-149).—The described water-culture technic adapted to laboratory and greenhouse facilities for studying the physiological importance of microelements involves the selec-

tion of suitable containers, purification of water by redistillation (with Pyrex condenser), and purification of molar stock solutions of the individual nutrient salts. Adaptations of Steinberg's CaCO_3 procedure for purifying the solution as a whole were devised for use with the stock solutions. The purity of the water and of each stock solution is tested prior to the experiment by a specially adapted dithizone test. With Pyrex containers and tested water and salts, media of reproducible purity were prepared at all times. Biological confirmation of the purity of nutrient media was obtained by growing plants in solutions deficient in Mn, Zn, and Cu, respectively. Plants consistently developed early deficiency symptoms characteristic of each of these elements.

Experiments on the action of copper on leaves [trans. title], H. DAXER (*Ztschr. Pflanzenkrankh. u. Pflanzenschutz*, 49 (1939), No. 4, pp. 225-251, figs 10).—Using a method of immersing individual leaves of pome, stone, and small fruit sorts in receptacles containing CuSO_4 solutions of varying concentration for different periods of time, the author studied their copper absorption and its effects. Preliminary tests indicated the great influence of temperature and previous leaf injuries on Cu-burning of the leaves. Experiments with unlimited immersion time indicated that 0.26-0.031 percent CuSO_4 solutions, besides killing the treated leaves, caused severe injuries by conduction, which are described. Grapes proved most resistant to such injuries, and stone fruits most susceptible, while the pome fruits lay between. Even a 0.003-0.00125 percent solution was still capable of injury, and the first dilution to induce no injury was a 0.00025 percent solution. Tests of varying duration of immersion indicated that the stronger solutions for a short time caused no appreciable injury, a 0.5 percent solution first causing leaf burn at 1-2 hr. immersion. Longer periods of wetting with very weak solutions also caused burning. The duration of immersion thus exerts at least as great an influence on burning as variations in the soluble Cu content of the mixture. It is deemed probable that in regions with frequent dews or fogs, mixtures containing 0.003 percent dissolved Cu may still cause burning. Tests with a leaf-petiole absorption method indicated that 0.13-0.64 mg. Cu taken up by the petiole can cause very severe "conduction" injuries, while 0.05-0.1 mg. caused in pome fruits only slight, but in stone fruits often medium to strong, injuries. In pome fruits 0.025 mg. Cu caused practically no injury, but on stone fruits slight conduction injury could still be noted. The action of Cu is said to depend not only on the amount but also on its concentration, and the varying tolerance of pome and stone fruits to depend on the differing cellular susceptibility to this element.

Antagonism of certain elements essential to plants toward chemically related toxic elements, A. M. HURD-KAREER. (U. S. D. A.). (*Plant Physiol.*, 14 (1939), No. 1, pp. 9-29, figs. 5).—"Arsenic injury is a function of the available phosphate concentration, with the protective arsenic:phosphorus ratio in nutrient solutions near 1:5. Rubidium injury is a function of the available potassium concentration, with the protective rubidium:potassium ratio in nutrient solutions near 1:2. Strontium injury is a function of the available calcium concentration, with the protective strontium:calcium ratio in nutrient solutions near 1:1. As a working hypothesis to explain these effects, the assumption is made that they are the result of some degree of unselectivity in absorption and utilization of chemically related elements, with the result that when an organic molecule is synthesized the chance of harmful substitution of the toxic element for the essential nutrient depends on the proportionate availability of the two. If the assumption proves to be correct, this particular type of antagonism may appropriately be designated 'mass antagonism.'" A bibliography of 39 references is included.

Factors influencing susceptibility of plants to sulphur dioxide injury, I. C. SETTESTROM and P. W. ZIMMERMAN (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 2, pp. 155-181, fig. 1).—The present paper attempts to provide some basis for evaluating the accumulated data on the subject and to afford a broader view of the mechanism of SO₂ injury. The new data have been obtained from factorial experiments designed to study a number of variables simultaneously and all have been subjected to analysis of variance. Based largely on the new work, but also in part on previous literature (30 references), the effects of the specific environal factors may be thus summarized: A plant is much more resistant to SO₂ at 40° F. and below than at higher temperatures, but there is no considerable variation in susceptibility above 40°, at least at 65°-105°. In general, resistance decreases with increase in relative humidity. Minor variations (at time of exposure) in soil moisture within the range adequate for growth are without effect on susceptibility, but with approach to the wilting point there is a marked increase in resistance. Plants grown under ample water supply are much more susceptible to injury than those without it. Plants grown in poor soil are more susceptible than those grown in good soil. The sulfate S content of the nutrient supply has no effect on susceptibility and pretreatment with SO₂ has no effect on susceptibility provided time is allowed for recovery between treatments. Plants grown under heavy shade are more susceptible than those grown without shade, but reduction of light intensity up to 35 percent has no effect. Young plants are much more resistant than are older ones, but middle-aged leaves are the most susceptible. Wet-ting of leaf surfaces has little or no effect.

It is deemed evident that many factors influence the susceptibility to SO₂ injury, and that caution must be exercised in applying experimental results to field conditions. It is believed that the so-called physiological factors (to be reported upon later) will shed more light on the mechanism of SO₂ injury, and that eventually susceptibility to SO₂ injury may be used as an indicator of certain physiological processes.

The use of indicator plants in locating seleniferous areas in western United States.—I. General, O. A. BEATH, C. S. GILBERT, and H. F. EPPSON. (Wyo. Expt. Sta.). (*Amer. Jour. Bot.*, 26 (1939), No. 4, pp. 257-269, figs. 14).—Continuing this line of investigation (E. S. R., 77, p. 600), the authors treat of the geographical and geological occurrences of 32 species of native selenium indicator plants, one or more of which occur in 12 western States. These indicators are defined as plants which contain significant amounts of Se during all or a major part of their annual growth and thrive only in its presence. A number of intermediate Se-bearing plants are also included which may contain it when rooted in Se-bearing rocks and soils but which are not restricted to such occurrences. The data presented are believed to warrant the following: "Selenium is not a constituent of all rocks; the amount of selenium absorbed by a given species varies greatly at different horizons within a given formation; the areas containing seleniferous plants in which the selenium is present in toxic amounts are limited; a very significant percentage of the vegetation growing on seleniferous soils does not absorb selenium in toxic amounts; seldom are indicator plants formed above an elevation of 8,500 ft.; all species of *Stanleya*, *Oenopsis*, and *Xylorrhiza* thus far studied are classed as indicator plants; only those species of *Astragalus* which occur in 5 of the 29 groups as clasified by Jones² are seleniferous; the characteristic odor given

² Revision of North American species of *Astragalus*, M. E. Jones. Salt Lake City, Utah, [1923], pp. 288+[42], [pls] 78.

off by some seleniferous *Astragali* is evidence that selenium is present. The origin, form, and distribution of selenium in soils is considered."

The taxonomy and ecology of *Agropyron spicatum* and *A. inerme*, R. F. DAUBENMIRE. (Univ. Idaho). (*Bul. Torrey Bot. Club*, 66 (1939), No. 5, pp. 327-329).—Because of the complete intergradation of the awn character (the sole basis of distinguishing the two so-called species) and because of the identical and unusual response to environal variation, the author recommends that a single species name, *A. spicatum*, be applied to the entire group, with broadened description as given.

The morphology and phylogenetic position of the genus *Jouvea* (Gramineae), P. WEATHERWAX (*Bul. Torrey Bot. Club*, 66 (1939), No. 5, pp. 315-325, figs. 11).—This is one of a series of studies on tropical American grasses.

GENETICS

Physiological aspects of genetics, G. W. BEADLE (*Ann. Rev. Physiol.*, 1 (1939), pp. 41-62).—A review of the more recent progress and problems along genetic lines.

The concept of species based on experiment, J. CLAUSEN, D. D. KECK, and W. M. HIESEY (*Amer. Jour. Bot.*, 26 (1939), No. 2, pp. 103-106).—Extensive experiments on several plant groups during a series of years, in which the problems were viewed from morphologic, geographic, ecologic, cytologic, genetic, and to some extent also physiologic angles, led the authors to conclude that plants are organized into groups, the members of each of which are able to interchange their genes freely in all proportions without detriment to the offspring. These natural groups are said to correspond fairly closely to the species of the moderately conservative taxonomists working with plants that reproduce sexually. This experimental concept for species is tabulated and discussed in detail, including the terminology.

Effect of colchicine on chromosome number and cell size in some horticultural plants, C. L. BECKER. (Minn. Expt. Sta.). (*Minn. Acad. Sci. Proc.*, 6 (1938), pp. 26-30).—Among the horticultural plants of different families treated, asparagus, among the vegetables, gave the most definite and quickest reactions, and it is deemed probable that several plants with larger cells and doubled chromosome number were obtained. Abnormal growth indicated possible chromosome doubling in some of the treated plants of beans, onions, peas, potatoes, and rhubarb. A number of annual and perennial flowers were also treated. *Amaryllis* flowers were deformed and proved to be sterile. Exceptionally large, vigorous shoots from some of the treated flax plants were believed to indicate possible chromosome doubling and larger cell size. Rough growth, indicating possible chromosome doubling in part of the tissues, was noted in a number of plants.

Inheritance of flower color in alfalfa, R. LEPPER, JR., and T. E. ODLAND. (R. I. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 3, pp. 209-216, figs. 2).—Crosses were made among inbred alfalfa strains with blue and white flowers (*Medicago sativa*) and yellow flower (*M. falcata*). Crosses with Grimm (purple) and Hansen (white) showed a dominance of purple in F_1 with a two-factor difference. A cross between a Grimm selection (purple) and *M. falcata* (yellow) was light purple, indicating a three-factor difference with purple epistatic to yellow. Failure of pure yellow to appear was assumed as due to modifying factors. A light-purple-flowered plant arising from a cross between white- and yellow-flowered strains led to the assumption that a factor for purple may be carried in the white-flowered parent in the presence of the recessive condition of the factor for color production. A three-factor dif-

ference was suggested. The wide color range and the many colored plants in proportion to white from a cross between Hansen white and Cossack variegated alfalfa strains suggested the presence of at least four factors. A hypothesis for interaction of flower colors is offered to explain results obtained in these crosses.

A crinkled leaf mutation in alfalfa, T. E. ODLAND and R. LEPPER, JR. (R. I. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 2, pp. 128-130, figs. 2).—An abnormality appearing in F_2 of *Medicago sativa* \times *M. fulcata* caused crinkling of leaf, which, when extensive, resulted in stunted growth and few flowers and seed. Behavior in F_2 and F_3 is described with factorial explanation.

An attempt to hybridize annual and perennial Avena species, L. P. V. JOHNSON and H. A. McLENNAN (*Canad. Jour. Res.*, 17 (1939), No. 2, Sect. C, pp. 35-37, fig. 1).—Cross pollination of annual with perennial species of *Avena* did not result in the production of hybrid seeds, but certain specific combinations, i. e., *A. sativa* Early Ripe pollinated by *A. pratensis* and by *A. montana*, produced ovary stimulation.

Occurrence of albino seedlings in Victoria oats, D. C. SMITH. (Minn. Expt. Sta.). (*Jour. Heredity*, 29 (1938), No. 2, pp. 63, 64, fig. 1).—Albinos appearing in a plant progeny of Victoria oats are illustrated, with references to albinism in oats and other cereals.

A zygotic lethal in chromosome 1 of maize and its linkage with neighboring genes, R. A. EMERSON. (Cornell Univ.). (*Genetics*, 24 (1939), No. 3, pp. 368-384).—A Bolivian corn with mosaic red pericarp and cob was found to have a recessive zygotic lethal, *zl*, closely linked with the pericarp-color gene, *P* and the nearby genes male-sterile 17, *ms₁₇*, and tassel-seed 2, *ts₂*. The effect of *zl* is to prevent homozygosis of genes with which it is closely linked and thus to change a 3:1 to a 2:1 F_2 ratio when linked with a dominant gene or to prevent the occurrence of the one class when linked with a recessive gene. Available data placed this group of genes of the short arm of chromosome 1 of corn in the order $sr \leftarrow ms_{17} \ 1.7 \ ts_2 \ 1.3 \ P \ 1.5 \ zl \rightarrow br$.

Translocations in maize involving chromosome 8, E. G. ANDERSON (*Genetics*, 24 (1939), No. 3, pp. 385-390).—Data are presented on linkage relations with *ms₈* (male sterile) and *j₁* (*japonica*) for nine translocations involving chromosome 8 in corn. The cytological positions of seven of these were determined. These genes are in the terminal one-fourth of the long arm of chromosome 8, with *j₁* nearest the end.

Morphology of two American wild species of cotton and of their hybrid, T. H. KEARNLY and I. E. WEBBER. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 6, pp. 445-459, pls. 2, figs. 5).—The hybrid resulting from a cross between *Gossypium armourianum* and *G. thurberi*, wild, lintless, 13-chromosome species of cotton, both native in North America, proved to be much more fertile than any other hybrid obtained by crossing two truly wild species of *Gossypium*. The gross morphology of several characters distinguishing the parent species, their expression in F_1 , and the segregation in respect to them in F_2 are considered in some detail. Segregation in a definite monohybrid ratio was indicated in regard to only one character, i. e., shape of cross section of the branchlets. Tendency to dominance of a greater number of genes from *G. armourianum* than from *G. thurberi* was evident in F_1 and F_2 . As in the gross morphological features, the hybrid resembled *G. armourianum* more closely than *G. thurberi* in histological characters. The compact mesophyll and closed fibrovascular cylinder of the petiole of *G. armourianum* were partly dominant to the relatively loose mesophyll and separate fibrovascular bundles of *G. thurberi*. Bearings of these findings upon phylogenetic and taxonomic problems in *Gossypium* and their possible significance in cotton breeding are discussed.

Sex mechanism in polyploids of *Melandrium*, H. E. WARMKE and A. F. BLAKESLEE (*Science*, 89 (1939), No. 2313, pp. 391, 392).—This is a summary of work on colchicine-induced polyploids of a white-flowered race of *M. dioicum*. It is concluded that the Y chromosome carried male-determining elements, contrary to the situation in *Drosophila* and *Rumex*, where this chromosome has been shown to play no role in primary sex determination.

A study of factors concerning herd management and herd production, L. COPELAND (*Jour. Dairy Sci.*, 22 (1939), No. 4, pp. 229–239, fig. 1).—Herd Improvement Registry records on 1,046 Jersey herds that had completed 12,274 lactations to January 1, 1938, were analyzed with reference to various management and production practices, including the percentage of dry cows, breeding efficiency, culling persistency, and production age of cows.

Note on a new recessive lethal in cattle, H. E. ANNETT (*Jour. Genet.*, 37 (1939), No. 2, pp. 301, 302, pl. 1).—The occurrence is noted of a lethal factor involving a lower jaw of half the normal length in 5 of 28 calves produced by a Shorthorn bull mated to his daughters. The condition was completely recessive to the normal.

Variations in the number of vertebrae of swine, V. A. FREEMAN. (Mich. Expt. Sta.). (*Jour. Heredity*, 30 (1939), No. 2, pp. 61–64, figs. 2).—Continuing these studies (E. S. R., 73, p. 526), the numbers of thoracic and lumbar vertebrae of 182 pigs of different breeds that were born dead or died soon after birth in the college herd averaged 20.52 ± 0.067 for Duroc-Jerseys and 21.27 ± 0.046 for Yorkshires. There were no significant differences between the vertebra numbers of ♂♂ and ♀♀. Pigs with the larger numbers of vertebrae had longer carcasses, and selection for body length probably resulted in an increased number of vertebrae. More than one pair of genes seemed to be involved in vertebra number.

A genetic approach to the control of adult mortality in the fowl, C. D. CARPENTER and J. H. MARTIN. (Univ. Ky.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 168–174, fig. 1).—Citing evidence of progress in reducing mortality by selection for resistance to pullorum disease reported by Roberts and Card (E. S. R., 74, p. 701) and to fowl typhoid reported by Lambert and Knox (E. S. R., 68, p. 823), the authors suggest controlling adult mortality genetically through line-breeding from large families of proved viability and finally by crossing superior lines to restore vigor lost through inbreeding.

The inheritance of melanism in pheasants, J. H. BRUCKNER. (Cornell Univ.). (*Jour. Heredity*, 30 (1939), No. 2, pp. 45–52, figs. 2).—The melanistic mutant in pheasants is primarily black throughout, both in chick and adult plumage. Several crosses with ringnecks showed that the character was due to a single, dominant, autosomal gene *M*. The single homozygous melanistic ♂ found produced 80 melanistic F₁s when crossed with ringneck ♀♀. The F₁ generation consisted of 136 melanistic and 41 ringneck birds, and the backcross produced almost equal numbers in more than 200 individuals. Evidently modifying genes were needed to induce the maximum expression of *M*. The possible relation of the melanistic mutant pheasants to the *Phasianus versicolor* species is discussed.

Sex and internal secretions, E. ALLEN, C. H. DANFORTH, and E. A. DOISY (Baltimore: Williams & Wilkins Co., 1939, 2. ed., pp. XXXVI+1346, pls. [3], figs. [455]).—Chapters bringing the development of the subjects up to date and based on recent surveys of the literature are presented in the different sections as follows: Biological basis of sex, including genetic and endocrine factors and their influence on secondary sex characteristics, by F. R. Lillie, C. B. Bridges, B. H. Willier, E. Witschi, L. V. Domm, and C. H. Danforth; physiology of the sex glands, germ cells, and accessory organs, including lactation,

by C. R. Moore, E. Allen, F. L. Hisaw, W. U. Gardner, C. G. Hartman, W. H. Newton, and C. W. Turner; biochemistry and assay of gonadal hormones, by F. C. Koch, E. A. Doisy, R. G. Gustavson, and W. M. Allen; the hypothysis and the gonadotropic hormones of blood and urine in relation to the reproductive system, by P. El. Smith, H. L. Fevold, E. T. Engle, A. E. Severinghaus, O. Riddle, and R. W. Bates; and additional factors in sex functions and endocrine applications in man, by W. O. Nelson, K. E. Mason, C. P. Stone, and J. P. Pratt.

Factors responsible for the sexual cycle in the English sparrow, *Passer domesticus* (Linnaeus): Ocular stimulation and spermatogenesis; effect of increased light ration on ovarian development, A. R. RINGOEN and A. KIRSCHBAUM. (Univ. Minn.). (*Jour. Expt. Zool.*, 80 (1939), No. 2, pp. 173-191, pls. 3, fig. 1).—Studies of the influence of additional light supplied to sparrows during the nonbreeding season (with and without blindfolding) on the germ cell development showed that light on nonblindfolded birds greatly stimulated testicular growth and to a lesser extent ovarian development and enlargement in most cases. These effects were prevented in most birds by blindfolding during the period when the extra light was supplied. Theelin injections partially duplicated the oviduct enlargement in light-treated ♀♀ but inhibited the ovarian development. A recent publication by Rowan (*E. S. R.*, 80, p. 34) has indicated that the effect of light in activating the pituitary is to stimulate general activity of the bird.

Sexual dimorphism in down and adult plumage of the Pilgrim goose, J. P. QUINN. (U. S. D. A.). (*Jour. Heredity*, 30 (1939), No. 2, pp. 55-57, figs. 2).—Sexual dimorphism in the Pilgrim goose permits ready sex identification in that ♂♂ have white or light-gray plumage and light-colored bills, whereas ♀♀ have darker down and dark bills. Differences seem more pronounced with age. The similarity between these geese and the Alabama geese described by Gordon (*E. S. R.*, 80, p. 326) is noted.

Regeneration of testis in the fowl, and its bearing on germ-cell theory, C. W. HOOKER and B. CUNNINGHAM (*Anat. Rec.*, 72 (1938), No. 3, pp. 371-385, pl. 1, fig. 1).—A small fragment of the testicle inadvertently left after castration causes the resumption of growth of the comb and head furnishings within 1 mo., but in 5 cases among approximately 500 capons resumption of comb growth was delayed for more than 6 mo. Evidence, including the testicular tissue removed from 3 of the 5 animals and histological study of the testicular tissue present, suggested the regeneration of testicular tissue resembling autoplasmic testes grafts, but full spermatogenesis was not observed. However, this evidence is taken to indicate that somatic (peritoneal) cells can be transformed into germ cells.

Mink breeding through the microscope, R. K. ENDERS. (U. S. D. A.). (*Amer. Fur Breeder*, 11 (1939), No. 7, pp. 6, 8, figs. 5).—This is a popular account of changes in the vaginal smear at different stages of the sexual cycle. Three fertilized ova were removed about 52 hr. after copulation. If the case is typical, minks may be considered to ovulate about 36 hr. after mating.

The effect of dilution and density on the fertilizing capacity of fowl sperm suspensions, S. S. MUNRO (*Canad. Jour. Res.*, 16 (1938), No. 10, Sect. D, pp. 281-299, figs. 2).—Study was made of the influence of dilutions up to 1:128 of fowl semen with a synthetic solution and reductions in the number of sperm of cockerels used for artificial insemination. Records of the fertility and hatchability of the eggs showed that 88 percent of the eggs laid on the second day after insemination were fertile. Fertility and hatchability were based on the eggs laid during the 10-day period beginning on the second day after insemination. Fertility dropped rapidly with dilutions, even of 1:2,

and reached a zero point with semen dilutions of 1:64. Variations in the amount of semen injected at different dilutions showed definitely that the decrease in fertility with diluted semen was not due to a decrease in the number of sperm. When sperm serum was used as the diluent, there was almost no decrease in fertility with dilutions as great as 1:64 if the number of sperm per insemination was not decreased, but decreases in the number of sperm per injection from 231.5 million to 57.9 million were associated with some decreases in fertility. Fertility was further lowered as the number of sperm was decreased, and when the number reached 1 million almost complete sterility followed. There seemed to be no correlation between fertility and hatchability of the fertile eggs.

Survival of deciduomata during lactation in the rat, R. A. LYON (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 2, pp. 151, 152).—Irritation of the endometrium from 5 to 17 days after parturition induced formation of the deciduomata in the rat. These had a shorter survival time when produced after the eleventh day of lactation than before, when survival was about 9 days.

Endocrine glands: Gonads, pituitary, and adrenals, H. M. EVANS. (Univ. Calif.). (*Ann. Rev. Physiol.*, 1 (1939), pp. 577-652).—A summary of the recent research on the endocrines and their influence on reproduction and lactation cycles, including reference to their role in general metabolism.

Criteria of placental endocrine activity in the mouse, W. H. NEWTON and F. J. LUTS (*Anat. Rec.*, 72 (1938), No. 3, pp. 333-349, pls. 2, fig. 1).—In addition to the three criteria of placental activity in the mouse, (1) inhibition of oestrus, (2) maintenance of body weight, and (3) stimulation of parturition,⁴ studies were made of the mammary glands of pregnant mice in which the fetuses were destroyed on the twelfth day, and in some cases in which the ovaries were removed at the time of fetal destruction with and without subsequent expulsion of the placentae. The results showed that the full development of the alveoli of the mammary glands was dependent on the presence of intact placentae. However, the degree of vacuolation was less than normal. The formation of an interpubic ligament of normal length was dependent on the presence of both placentae and ovaries.

The technic of hypophysectomy in the rabbit, W. H. NEWTON (*Endocrinology*, 24 (1939), No. 4, pp. 468-474, fig. 1).—Methods successful in the removal of the pituitaries from about 75 percent of the rabbits operated are described.

Significance of operative technic in the removal of the pituitary: A new transphenoidal approach to the pituitary of the dog and notes on the buccal approach to the pituitary in the rabbit, O. COPE and G. A. DONALDSON (*Endocrinology*, 24 (1939), No. 4, pp. 475-487, figs. 14).—Advantages and method of a new parapharyngeal approach to the pituitary in the dog and rabbit are presented.

Effects of light and darkness on activity of the pituitary of the rat, V. M. FISKE (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 2, pp. 189-191).—Studies of the influence of light and darkness on the age of attainment of sex maturity in rats showed that in ♀♀ kept in the light the vaginas averaged to open earlier, and assays of the pituitaries from such animals showed larger amounts of follicle-stimulating hormone than were present in corresponding ♀♀ kept in the dark. However, darkness seemed to favor the production of larger amounts of luteinizing hormone. The pituitaries, testes, and seminal vesicles of ♂ rats kept from 21 to 175 days of age in the light were larger than those of ♂♂ kept in the dark during this period.

⁴ Jour. Physiol., 84 (1935), No. 2, pp. 196-207, figs. 6.

Biphasic effect of male sex hormone on the pituitary of the female rat, S. C. FREED, J. P. GREENHILL, and S. SOSKIN (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 3, pp. 440-442).—Different sized doses of testosterone propionate were found to have different effects when administered over a 16-day period to adult ♀ rats. A small dose, 0.05 mg., caused ovarian atrophy, whereas the larger dose, 1 mg., caused persistent corpora lutea and progestationalike changes in the uterus. Cessation of oestrous cycles followed the administration of all doses.

Augmentation of pituitary gonadotropic hormone by chlorophyll, plant growth hormones, and hemin, W. R. BRENNEMAN (*Endocrinology*, 24 (1939), No. 4, pp. 488-493).—Alcohol or water-soluble chlorophyll, two plant hormones, or hemin with pyridine, mixed with pituitary gonadotropic extract in vitro augmented its influence on the size of the ovaries of immature rats and the testes and comb of chicks. The augmenting effects were questionable or negative when administered separately.

Extraction and standardization of pituitary follicle-stimulating and luteinizing hormones, H. L. FEVOLD (*Endocrinology*, 24 (1939), No. 4, pp. 435-446).—The potency of extract, residue, and unextracted pituitary tissue from horses, hogs, sheep, and rats was compared. Assay methods for the follicle-stimulating and luteinizing hormones before and after separation are described, based on ovarian weights and structural changes produced.

Chemical differences of the follicle-stimulating and luteinizing hormones of the pituitary, H. L. FEVOLD (*Jour. Biol. Chem.*, 128 (1939), No. 1, pp. 83-92).—In tests with immature ♂ and ♀ rats it was found that the follicle-stimulating hormone in water-soluble stock solutions from fresh sheep pituitaries was precipitated and inactivated by picrolonic, picric, and flavianic acids. Luteinizing hormone was not affected. The luteinizing hormone stimulated the interstitial cells of the testes to secrete ♂ hormone, a reaction that was augmented by the follicle-stimulating hormone, although the follicle-stimulating hormone alone was inactive. Luteinizing hormone was active on subcutaneous or intraperitoneal injection, but the follicle-stimulating hormone was only active in the former case.

The effect of sex hormones on the combs of castrated and normal cocks: Direct effect of folliculin on the cock's comb, J. MORATÓ-MANABO and A. ALBREUX (*Endocrinology*, 24 (1939), No. 4, pp. 518-522, figs. 2).—Neutralizing effects of ♂ hormone and folliculin when mixed in vitro prior to application in comb tests were verified. By dividing the combs of capons into anterior and posterior portions and treating one with folliculin it was found that the decreased size resulting was much greater in the half to which the hormone was directly applied than in the other half. A similar local effect was noted in increased comb growth induced by testosterone applied to a portion of the comb even though considerable testicular changes were induced. Assays of ♀ or ♂ hormone must be made on materials freed of the hormone of the opposite sex.

Improved procedure for biological titration of estrogenic and gonadotropic hormones in sera of pregnant women, A. EL RAKOFF (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 2, pp. 195, 196).—The use of unextracted serum, rather than extracted whole blood, was found to provide a more sensitive pregnancy test for the presence of oestrogenic hormone and gonadotropic hormone in the blood of pregnant women, as determined in experiments on castrated and immature ♀ mice, respectively.

Maintenance of the corpus luteum and inhibition of parturition in the rabbit by injection of estrogenic hormone, G. P. HECKEL and W. M. ALLEN (*Endocrinology*, 24 (1939), No. 2, pp. 137-143, figs. 5).—The continued admin-

istration of oestrone or oestradiol monobenzoate to rabbits during the last third of the gestation period caused persistence of the functioning corpora lutea and postponed parturition. To obtain this result the ovaries must be present. All evidence pointed to the role of the corpora lutea in inhibiting parturition. Doses of oestrogenic hormone sufficient to delay parturition always caused death of the fetuses. Single doses were lethal without delaying parturition.

Copulatory activity in adult male rats following castration and injections of testosterone propionate, C. P. STONE (*Endocrinology*, 24 (1939), No. 2, pp. 165-174, figs. 2).—Sexual activity as measured by copulatory frequency was almost completely restored in castrated ♂ rats by injections of 1.25 mg. of testosterone propionate. After injections ceased sexual aggressiveness gradually waned, as following castration, but it was restored by further hormone treatment. The sexual drive of castrates treated with testosterone propionate, as measured in obstruction tests, was considered below that of normals.

The effect of prolonged testosterone propionate administration on the immature and adult female rat, M. and C. MAZER (*Endocrinology*, 24 (1939), No. 2, pp. 175-181, figs. 10).—Prolonged administration of testosterone propionate to immature ♀ rats caused a decrease in the weights of the pituitaries, adrenals, ovaries, and uteri and inhibited oestrus. The adult ♀ showed a similar reaction, but there was no significant decrease in pituitary weight. The ovarian atrophy was considered secondary to pituitary inhibition.

The effect of progestation-injections in ovariectomized guinea-pigs, R. LUTF and L. WALLMAN (*Acta Path. et Microbiol. Scand.*, 16 (1939), No. 1, pp. 103-106).—Injections of synthetic progesterone in oil into ovariectomized guinea pigs did not induce the same type of virilism that seems to result from extracts of the corpus luteum.

Induction of mating in the dog with pregnancy urine extract, J. H. LEATHER and J. A. MORRELL (*Endocrinology*, 24 (1939), No. 2, pp. 149-156, figs. 6).—The daily administration of 10, 25, or 50 rat units of pregnancy urine extract (Follutein) per kilogram to 11 anoestrous bitches induced mating in from 8 to 26 days. Ovariectomized ♀♀ failed to respond. Although follicle development was initiated, ovulation did not occur. Vaginal smears did not show full oestrus and pseudopregnancy did not follow mating.

Effect of pregnancy urine extract on lactation in the rat, I. L. HATHAWAY, H. P. DAVIS, R. P. REECE, and J. W. BARTLETT. (Nebr. and N. J. Expt. Stas.). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 2, pp. 214-218).—Contrary to previous reports regarding the inhibition of lactation by pregnancy urine extracts (E. S. R., 73, p. 323; 79, p. 616), the injection of 100 rat units of Antuitrin-S daily during the first 5 days after parturition had no marked influence on lactation. The rate of growth of the suckling young was reduced as much as 22 to 33 percent by larger doses of the hormone, which also made the dams sick. Injections of similar amounts of physiological salt solution did not inhibit lactation.

Comparison of intravaginal and subcutaneous tests for estrone and estradiol monobenzoate, L. B. STADLER and W. R. LYONS. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 3, pp. 562-564).—Although it was found that oestradiol monobenzoate when administered subcutaneously was about 5 to 10 times as potent as oestrone (E. S. R., 75, p. 329), the relative potencies of these substances in inducing cornification after intravaginal administration was not known. The intravaginal units of oestrone and oestradiol monobenzoate were approximately 0.02 and from 0.01 to 0.005, respectively, of the subcutaneous units of these substances. Oestradiol monobenzoate was about

10 and 30 times, respectively, as potent as oestrone when tested subcutaneously and intravaginally.

Age and sex differences in hormone content of the rabbit hypophysis, J. A. SEXTON, JR., and H. S. N. GREENE (*Endocrinology*, 24 (1939), No. 4, pp. 494-502).—Study was made of the response of the thyroids, ovaries, and adrenals of immature guinea pigs to implants of pituitaries from 96 rabbits ranging in age from 10 days to 45 mo. The pituitaries from the immature rabbits at 10 days of age elicited no gonadotropic response, but an increasing follicle response was noted after 15 days (with luteinizing effects as well) from glands from rabbits older than 28 days. Pituitaries from mature animals stimulated follicle growth and luteinization. The gonadotropic stimulation was greater from young ♀♀ than from ♂♂. Thyroid and adrenal stimulation were noted from rabbits of all ages, but the amounts of stimulation induced varied with the sex and age of the rabbit.

The local effect of luteohormone on uterine mucosa of the infantile rabbit, J. C. MUSSIO FOURNIER, A. S. ALBRIEUX, and O. GROSSO (*Endocrinology*, 24 (1939), No. 4, pp. 515-517, figs. 6).—Studies with 60 infantile rabbits prepared for 8 days with follicular hormone showed that the uterine injection of progesterone brought about a more decided change in the mucous membrane than when the same dose was given subcutaneously. Deposition under the peritoneum around the horn gave a less pronounced reaction.

Increased sensitivity of the vagina to theelin, in the chronic castrated rat, as induced by the cotton swab procedure, F. E. EMERY and E. L. SCHWABE (*Anat. Rec.*, 72 (1938), No. 3, pp. 303-311, pl. 1, fig. 1).—Frequent vaginal smears with a cotton swab in rats from 6 to 10 mo. after ovariectomy were found to give positive oestral smears. The vaginal epithelium became more sensitive to theelin than when vaginal smears were made by the pipette method.

Artificial insemination of farm animals, V. K. MILOVANOV (*Iskusstvennoe osemenenie sel'skokhoziaistvennykh zhivotnykh. Moskva: Gosud. Izdatel.*, 1938, 4. ed., pp. 368, figs. 227).—A discussion of the instruments used in collecting semen and methods employed in artificial insemination of all classes of livestock and poultry in Russia.

A serological investigation of bird eggs, with special reference to the possibility of differentiating species of birds [trans. title], O. SIEVERS (*Acta Path. et Microbiol. Scand.*, 16 (1939), No. 1, pp. 44-98).—Differences in the serological reactions of different birds are noted.

FIELD CROPS

[Field crops work in Alaska, 1937] (Alaska Sta. Bul. 7 [1938], pp. 17, 18, 19, 21, 22, 23-26, 31-33, fig. 1).—Continued experiments (E. S. R., 77, p. 770) at the station and Matanuska Substation, reported on briefly, included variety tests with wheat, barley, oats, corn, sweet corn, grain sorghum, potatoes, soybeans, timothy, and other forage legumes and grasses; tests of legumes and other crops for winter hardiness; fertilizer tests with potatoes and brome grass; investigation of the hardiness, growth habit, and fruiting of the yellow flowered alfalfa (*Medicago falcata*): pasture studies; and crop rotations. Average acre yields of the several cereals, potatoes, and hay are also recorded.

[Field crops research by the Georgia Coastal Plain Station, 1937]. (Partly coop. Ga. Expt. Sta., U. S. D. A., Univ. Ga., et al.). (*Georgia Coastal Plain Sta. Bul.* 29 (1938), pp. 9, 10, 14-32, 32-40, 80-83, 119-125, 131, figs. 7).—Experimentation with field crops again reviewed briefly (E. S. R., 80, p. 36) for 1937 and for different periods of years comprised variety tests with cotton, corn

for yield and resistance to weevils, oats, wheat, rye, grain sorghum, sorgo, sweetpotatoes, perilla, peanuts, lespedeza, soybeans for seed and forage, cowpeas, velvetbeans, crotalaria, winter cover crops, pasture grasses, and miscellaneous summer forage crops; breeding work with corn, cotton, oats, peanuts, soybeans, and pasture grasses; fertilizer experiments with corn, oats, and peanuts; winter cover crops for cotton and corn; and cultural (including planting) experiments with oats, wheat, peanuts, soybeans, velvetbeans, crotalaria, and winter cover crops. Fertilizer work with cotton, tobacco, and sweetpotatoes dealt with formulas, carriers of nitrogen, phosphorus, and potassium, and also with fertilizer placement for cotton and tobacco; nitrogen and potassium top dressings for cotton and sweetpotatoes; secondary nutrient elements for cotton; boron tests and fractional applications with tobacco; and ratios of organic : nonorganic nitrogen with sweetpotatoes. General recommendations on soils, varieties, plant beds, fertilizers, spacing and topping, and curing for flue-cured tobacco are also included.

Biennial report of the Northeast Louisiana Experiment Station, St. Joseph, Louisiana, 1937-1938, C. B. HADDON (*Louisiana Sta., Northeast Louisiana Sta. Bien. Rpt. 1937-38, pp. 23*).—Continued field crops experiments (E. S. R., 77, p. 181) reported on briefly included fertilizer experiments comprising carriers of nitrogen and potassium and rates of sodium nitrate, mixed fertilizers, production after different legume winter cover crops and after vetch seeded at different rates and turned under on several dates, yields following corn and soybeans, and after nitrogen carriers as supplements to vetch, all with cotton; spacing tests with cotton and corn; comparison of nitrogen sources for side dressing corn; corn alone v. corn with soybeans; and variety tests with cotton, corn (and hybrids), oats, alfalfa, and lespedeza.

[Achievements of agronomic research in Nebraska]. (Partly coop. U. S. D. A.). (*Nebraska Sta. Circ. 60 (1939), pp. 26-39, 43-46, figs. 7*).—Major accomplishments in research with field crops, described in those pages as made by the station since its establishment, were obtained in breeding work with corn and corn hybrids, wheat, alfalfa, sweetclover, grain sorghum, sorgo, and potatoes; adaptation studies with corn, corn hybrids, alfalfa, and oats; variety trials with corn, wheat, grain sorghum, sorgo, oats, barley, alfalfa, and potatoes; cultural experiments with corn, wheat, alfalfa, oats, barley, and potatoes; winter hardiness studies with wheat; milling and baking tests with wheat; fertilizer and rotation experiments with sugar beets; storage and seed potato production experiments with potatoes; studies of native meadow and pasture plants; and weed control investigations. Meritorious crop varieties developed or introduced by the station are noted.

[Field crops studies in Western Washington], M. S. GRUNDER. (Partly coop. U. S. D. A. et al.). (*Western Washington Sta. Rpt. 1938, pp. 10-14*).—Progress results are reported briefly from pasture studies on logged-off land, seedings of forage plants on burned-over land, rate of seeding tests with hairy vetch and a rye support crop, variety tests with soybeans (for seed and green forage) and alfalfa, analysis of flat pea at different stages of development, and nurseries for improvement of Italian ryegrass, orchard grass, and Ladino clover.

Preliminary tests with some plant hormones in the rooting of cuttings of certain forage plants, F. S. NOWOSAD (*Sci. Agr., 19 (1939), No. 7, pp. 494-503, pls. 5*).—When naphthyl-acetic and indolyl-acetic acids were applied to cuttings of timothy, alfalfa, and red clover, results indicated that the effects of the treatments are influenced by temperature, humidity, and light in the greenhouse; by degree of maturity of the tissue of cuttings; by pH and chemical concentration of the medium in which planted; and by the type and concentration of the hormone. No treatments gave satisfactory results in rooting timothy cuttings.

Optimum treatments for alfalfa and red clover approximated any one of the following with naphthyl-acetic acid: 50 p. p. m. in talc applied to the fresh scar of the cutting, basal ends of cuttings dipped for 12 hr. in 5-50 p. p. m. solution, or 10 p. p. m. fed in solution in nutrient culture solution.

A relationship between pollination and nodulation of the Leguminosae, J. K. WILSON. (Cornell Univ.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 2, pp. 159-170).—The evidence presented shows that a relationship may exist between pollination and nodulation of species of legumes. Plants completely self-pollinating may not bear nodules or will symbiose with few strains of rhizobia. If cross-pollination is obligatory, the plant will symbiose with a rather large number of strains. Strains of rhizobia symbiosing with self-pollinating plants appear predominantly monotrichic while those symbiosing with cross-pollinating plants seem predominantly multitrichic, although both morphological types may be found symbiosing with cross-pollinating plants. Such a relationship does not seem to correlate in any way with the order, tribe, genus, or species of the plants, except as it may be influenced by pollination. This suggested relationship, if valid, is expected to place symbiosis on a heritable basis and in the same category as certain heritable plant diseases.

Grasses and legumes for pasture and hay, W. WHITMAN, T. E. STOA, and H. C. HANSON. (Coop. U. S. D. A.). (*North Dakota Sta. Circ.* 64 (1939), pp. 26 figs. 16).—Practices in pasture and hay production, based extensively on cooperative research and experience and discussed in some detail, include choice of perennial grasses and legumes; selection of land, seedbed preparation, seeding and other cultural practices, and seeds mixtures for eastern and western North Dakota; seeding eroded fields; use of supplementary forage crops; and fencing and management.

Improving the quality of hay, A. H. LEWIS (*Jour. Min. Agr. [Gt. Brit.]*, 46 (1939), No. 1, pp. 77-82).—Confirmation under British conditions of the results of Sprague and Hawkins (*E. S. R.*, 79, p. 327) is reported.

Alfalfa nursery technic, H. M. TYSDAL and T. A. KIESSELBACH. (U. S. D. A. and Nebr. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 2, pp. 83-98, fig. 1).—Alfalfa nursery plant technic was studied, 1935-37, with respect to number of rows per plat, distance between rows, alley space between plats, removal of border rows at harvest, interplat varietal competition, spacing of plants within the row, rates of planting, and plat distribution. The Hardistan and Ladak varieties were compared in 16 replications of 9 types of nursery plats and adjacent field plats. The nursery plats were 16 ft. long with variations of 1, 3, 4, and 8 rows per plat, and the row-spacings under comparison were 7, 18, and 24 in. All plats were solid-drilled except in one group where the plants were spaced 12 in. in rows 24 in. apart.

The most serviceable types of plat for advanced nursery testing, based on specific principles indicated by these studies and general experience with alfalfa nurseries, appear to be somewhat optional among solid-drilled from 5 to 8 rows spaced 7 in. apart, with a 12- to 14-in. alley between border rows, or solid-drilled from 3 to 5 rows spaced 12 in. apart with an 18-in. alley between border rows. Since removal of border rows is difficult and expensive with alfalfa and since very little error has been found with such plats due to border effect, it is suggested that the entire plat may be harvested for yield, with the possible exception of removing border rows in case adjacent stands are decidedly different. The plats may be 16 ft. or longer, and the alley space should be included in the plat area. Single rows spaced from 18 to 24 in. apart are permissible for preliminary nursery testing.

Barley and malt studies.—II, Experimental malting of barleys grown in 1935, J. G. and A. D. DICKSON, H. L. SHANDS, and B. A. BURKHART. (U. S. D. A. and Wis. Expt. Sta. coop. 11 expt. stas. et al.). (*Cereal Chem.*, 14 (1937), No. 3, pp. 316-327, figs. 5).—The malting data reported for samples of commercial barley tested under commercial and experimental procedure, for show samples from 6 States, and for 5 varieties grown at 11 experiment stations in uniform regional series in 1935 supplement data on the previous crop (E. S. R., 74, p. 479).

An estimation of the number of top-crossed plants required for adequate representation of a corn variety, G. F. SPRAGUE. (Mo. Expt. Sta. and U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 1, pp. 11-16).—Study of variance among top crosses on individual plants of Reid Yellow Dent and Krug corn in relation to variance associated with random error indicated that the variance of means of samples of from 10 to 20 plants would be unimportant compared with that due to random error. Preparation of seed for planting from bulked seed from this many plants would not introduce serious errors unless the size of samples drawn from the bulked lot is small or individual plants contribute widely different numbers of seeds to the total population.

Field corn in Massachusetts, W. G. COLBY and R. W. DONALDSON (*Massachusetts Sta. Bul.* 356 (1939), pp. 16, fig. 1).—Information is given on the adaptations of corn in Massachusetts; choice of varieties and hybrids; corn areas; cultural methods and field practices, especially fertilization; and control of European corn borer. Varieties and hybrids grown in comparison at Amherst, 1936-38, are grouped according to maturities with maturity dates and grain and stover yields.

The foliar diagnosis of *Zea mays* subjected to differential fertilizer treatment, W. THOMAS and W. B. MACK. (Pa. Expt. Sta.). (*Jour. Agr. Res.* [U. S.] 58 (1939). No. 7, pp. 477-491, figs. 6).—Corn plants, examined by the method of foliar diagnosis (E. S. R., 80, p. 188), were grown on plats of the Jordan fertility experiment, unlimed but treated as follows since 1881: Check (0), N, P, K, NP, NK, PK, and NPK. The nitrogen carrier was dried blood; phosphorus, superphosphate; and potassium, the chloride.

A relationship existed between the N percentage in the dried leaf and in the fertilizer but none between N in the leaf and yield nor between N in the fertilizer and yield except when accompanied by P and K. Relationships existed between the P percentage in the leaf and in the fertilizer, between P in the leaf and yield, and between P in the fertilizer and yield. No relationship existed between the K contents in the leaf and fertilizer, between the variation of K in the leaf and variations in yield, or between K in the fertilizer and yield. The percentage content of CaO and MgO in the leaves of plants receiving P, NP was much higher than in those receiving PK, NPK.

Analyses of the third leaf from the base at four periods during growth indicated that low intensities of nutrition are associated with low yields in check, P, N, and NP treatments and high intensities with high yields in PK and NPK; but when "luxuskonsumption" of potash occurs relatively low yields may be associated with relatively high intensities of nutrition as in K and NK. The composition of the composite NPK-unit (E. S. R., 79, p. 23) was related to grain yields: Group 1, poorly nourished plants, check, NK, N, and K, are characterized by low P in the NPK unit; group 2, better nourished plants, P and NP, with very high P, high N, and very low K in the NPK unit; and group 3, best nourished plants, PK and NPK, with values for N, P, and K intermediate between those of groups 1 and 2.

Cotton breeding and seed supply, A. BRIZI (*Roma: Internat. Inst. Agr.*, 1938, pp. 71, figs. 5).—Information is presented on breeding objectives, species

and varieties of *Gossypium*, propagation and conservation of varieties and strains, and trends of cotton breeding in major cotton growing countries (with 63 references), as an appendix to the monograph on World Cotton Production and Trade (E. S. R., 78, p. 119).

Viability of seeds of cotton as affected by moisture and age under different methods of storing. F. B. FLORES (*Philippine Jour. Agr.*, 9 (1938), No. 4, pp. 347-356, fig. 1).—Sun-dried cottonseed, whether delinted, ginned, or in seed cotton, when stored in airtight containers retained enough viability for planting purposes after 1 yr. in storage, while the same kind of seeds kept in burlap sacks were useless after 6 mo. in storage. Sun-dried and air-dried seed cotton maintained higher viability percentages than either ginned or delinted cottonseeds in practically all the tests as storage was prolonged. A definite relation was indicated between the moisture content of the seeds during storage and the rapidity of deterioration.

Relation of temperature and moisture content to longevity of Chewings fescue seed. V. KEARNS and E. H. TOOLE (*U. S. Dept. Agr., Tech. Bul.* 670 (1939), pp. 27, pl. 1).—Chewings fescue (*Festuca rubra* var. *commutata*) seed shipped under different conditions from New Zealand and Virginia- and Oregon-grown seed of high viability were stored at different moisture contents and temperatures, and their germination was determined at intervals. Advantages of shipping seed under cool storage conditions in oversea transit were lost in a few months after arrival in the United States unless the seed was stored subsequently at as low as 2° C. or unless it was dried out after arrival to not exceed 10-percent moisture. Seed dried before oversea shipment and kept dry showed after from 18 to 26 months' storage at room temperature germination equal to that shown by nondried seed on arrival in this country. See also an earlier note by Foy (E. S. R., 73, p. 313).

The tests of domestic seed, ranging from about 8 to 14 percent moisture content and stored in sealed jars at -10°, 2°, 10°, 20°, and 30°, showed the direct association of moisture content and storage temperature on the life of the seed. Fescue seed lost vitality very rapidly at 30° if the moisture content was high. At 30° germination fell about 20 percent in 5 weeks, 4 mo., and 12 mo. at moisture contents of 14, 12, and 10 percent, respectively. The seed was practically dead in from 3 to 5 mo. at 14-percent moisture and in 8 mo. at 12-percent moisture. When stored at 30° with a moisture content of about 10 percent, fescue seed retained vitality much longer than when stored at 20° with about 14-percent moisture, but not as long as seed stored at 10° with a 14-percent moisture content. However, seed with 10-percent moisture stored at 20° germinated above 90 percent after 26 months' storage v. 58 and 77 percent for seed having a 14-percent moisture stored at 10°.

The moisture content of fescue seed stored at 30° evidently should not exceed 8 percent, stored at 20° 10 percent, and stored at 10° not over 12 percent for long-time storage. No benefit comes from shipping seed with high moisture content under cool-storage conditions, because it will lose vitality on arrival in this country as rapidly as seed not shipped under cool storage and its initial germination on arrival would only serve to mislead the trade. Seed that dies slowly goes through a period when many sprouts develop abnormally during germination. Such sprouts are worthless for they would never develop to maturity.

Temperature and other factors affecting the germination of fescue seed. V. KEARNS and E. H. TOOLE (*U. S. Dept. Agr., Tech. Bul.* 638 (1939), pp. 36).—Germination studies with several species of *Festuca* showed that fescue seed tested immediately after harvest required a relatively low temperature for germination, especially in seed collected when immature or mature compared

to seed collected when dead ripe. With fresh seed, optimum temperatures for germination were for mixed commercial strains of *F. rubra* 10° C.; Chewings fescue (*F. rubra commutata*), creeping red fescue (*F. rubra*), and reed fescue (*F. elatior arundinacea*) from 15° to 25°; hair fescue (*F. capillata*) from 10° to 25°; and for meadow fescue (*F. elatior*) 15°, 20°, or from 15° to 25°. The test period needed for maximum germination at the optimum temperature was for meadow fescue 14 days; for Chewings, creeping red, and reed fescues, and *F. rubra* strains 21; and for hair fescue 28 days. As the seed aged it germinated over a wider range of temperatures. A few months after harvest fescue seed germinated its maximum at the alternation from 20° to 30°, although the rate was slower than at lower temperatures.

For fresh seed of Chewings fescue the best constant temperature was 10°, but both rate and final percentage of germination for older seed were lower at 10° and the best constant temperature rose to 15° and 20°. Hair fescue and *F. rubra* strains made the same change in response to temperature with age but did not decrease in germination at 10°. Fresh seed of hair, creeping red, and reed fescues showed low germination at constant temperatures, the best being 10° for hair fescue and 15° for the other two species. Hair fescue, which required a very low temperature alternation when fresh, needed a longer period after harvest before it would give a maximum germination at from 20° to 30° than species showing from 15° to 25° as optimum for fresh seed. Seed of all species prechilled at 5° for about 7 days gave increased germination at temperatures ordinarily too high for complete germination of fresh seed or that not after-ripened. Seed of reed and hair fescues kept in dry storage at low temperatures showed a temperature response at high constant temperatures comparable to seed not after-ripened. Hair fescue was the only one responding to light and nitrate in addition to optimum temperature. Light and nitrate benefited the other fescues only at temperatures unfavorable for complete germination.

Seed flax in eastern Washington, O. E. BARBEE and E. G. SCHAFER (*Washington Sta. Bul.* 370 (1939), pp. 16, figs. 3).—Practices recommended for growing seed flax in eastern Washington, based on experimental results and experience, include the choice of the Bison variety, planting in early spring at the rate of from 40 to 45 lb. per acre not deeper than 1 in. on a well-prepared seedbed on weed-free land and harvesting with a combine if ripe and dry, or if not dry or containing green weeds, cutting with the binder or swather and drying before threshing. Alfalfa and sweetclover have made good stands when sown with flax as a nurse crop.

The acre yield of flax obtained in 1938 by 33 farmers reporting on 2,349 acres varied from 4 to 14 bu., averaging 7 bu. When local prices of December 26, 1938, were applied to yields of different crops obtained under experiment, flax returned a lower acre value than winter wheat, oats, and barley, but higher than spring wheat and peas. The spread in yield between flax and wheat evidently is greater in Washington than in the North Central States, and flax growing does not compare as favorably with wheat in Washington as in that area. Information is also given on the national status of the crop and its commercial movement.

Sun injury to cut potato seed, W. C. EDMUNDSON. (U. S. D. A.). (*Amer. Potato Jour.*, 16 (1939), No. 4, pp. 98-103).—Yields and stands following the planting at Greeley, Colo., in 1937 and 1938 of seed of Rural New Yorker No. 2 and Triumph potatoes, freshly cut and suberized, exposed for 0, 2, and 4 hr., and whole seed not exposed indicated that in sections where planting of the late crop is delayed until the temperature is high, cut seed may be injured by

direct exposure to the sun. Seed not exposed, whether freshly cut, suberized, or whole, produced similar yields in the 2 yr. Although suberized seed was injured by direct exposure, the severest injury was sustained by freshly cut seed, the extent being governed largely by duration of exposure.

Immediate germination of certain selfed and hybrid potato seed, M. L. ODLAND. (Minn. Expt. Sta.). (*Amer. Potato Jour.*, 15 (1938), No. 3, pp. 67-71).—Study of 22 genetically different samples of recently harvested potato seed revealed marked differences in degree of delayed germination. Certain samples completed germination before transplanting time whereas other samples required about 90 days to complete germination. Seed 1 yr. or older when planted may exhibit delayed germination, although one lot of selfed seed showed no delayed germination over 2.5 yr.

Correlation of seedling performance in the greenhouse and subsequent yield in the field, J. R. LIVERMORE. (Cornell Univ.). (*Amer. Potato Jour.*, 16 (1939), No. 2, pp. 41-43).—Analysis of data from a greenhouse planting of approximately 2,000 potato seeds in 1936 and a field planting of the tubers from these seedlings in 1937 at Ithaca, N. Y., indicated that the association between greenhouse growth and field yield was so slight that greenhouse seedling growth would be of little help in detecting superior productivity.

The comparative productiveness of seed potatoes grown on sandy and on peat soils in central Wisconsin, A. R. ALBERT, R. H. LARSON, and J. C. WALKER. (Univ. Wis.). (*Amer. Potato Jour.*, 16 (1939), No. 1, pp. 16-24).—Seed potatoes of several varieties grown on peat soil outyielded seed from mineral soils when compared, 1934-37, in several localities.

Reasons for the low average yields of potatoes in Ohio, J. BUSHNELL. (Ohio Expt. Sta.). (*Amer. Potato Jour.*, 16 (1939), No. 3, pp. 67-70, fig. 1).—The current low average yield of potatoes in Ohio is attributed to the growing of a large proportion of the crop in small patches on farms not equipped to spray properly, with yields seriously reduced by flea beetles and leafhoppers; the ordinary rotations and methods of handling the soil which do not maintain an adequately loose condition for potatoes; and the high summer temperature which probably would of itself prevent Ohio yields from equaling the yields of cooler potato districts.

Fertilizer and nutrition studies with the potato in 1938, O. SMITH. (Cornell Univ.). (*Amer. Potato Jour.*, 16 (1939), No. 3, pp. 53-66).—Results of investigations during 1938 on fertilizers, cover crops and green manures, soil reaction, and sand and solution culture studies with the potato are summarized, with a list of 87 titles.

Further studies on the placement of fertilizer for potatoes, B. E. BROWN, H. H. ZIMMERLEY, G. V. C. HOUGHLAND, W. H. REDDIT, and L. G. SCHOENLIEBER. (U. S. D. A. and Va. Truck Expt. Sta.). (*Amer. Potato Jour.*, 16 (1939), No. 4, pp. 81-93, figs. 4).—Previous cooperative studies (E. S. R., 76, p. 620), showing that in general superior results followed application of fertilizer in a band on each side of, about 2 in. from, and practically on a level with the potato seed piece, were supplemented by a placement study comparing complete fertilizer with separate ingredients. Yields per acre, 1936 and 1937, on Sassaparilla sandy loam at Onley, Va., after 6-6-5 (NPK) fertilizer in furrow, averaged 163.5 bu.; 6-6-5 on each side, 166; 0-6-5 in furrow, 6-0-0 on each side 174; 0-6-5 on each side, 6-0-0 in furrow 141.5; 6-0-5 in furrow, 0-6-0 on each side 135.5; 6-0-5 on each side, 0-6-0 in furrow 193.5; 6-6-0 in furrow, 0-0-5 on each side 148; and 6-6-0 on each side, 0-0-5 in furrow 159 bu. Nitrogen carriers when applied in the row retarded emergence and lowered yields to the greatest extent. Potash had a minor retarding influence. The final stand was less affected, but retardation in emergence indicated a physiological set-back from which plants

concerned failed to recover enough to produce normal yields. Placement of superphosphate in contact with the seed piece, especially since it exerts no appreciable injury at normal rates, appeared desirable. Since certain nitrogen carriers when in contact with the seed piece are most injurious, they might be placed on each side in combination with the potassium materials to avoid injury and to promote fertilizer efficiency.

Eighteen varieties of edible soybeans: Their adaptability, acceptability, culture, and characteristics, J. W. LLOYD and W. L. BURLISON. (Coop. U. S. D. A.). (*Illinois Sta. Bul.* 453 (1939), pp. 381-439, pl. 1, figs. 15).—Cooperative tests in 54 counties indicated the adaptation of the vegetable type of soybeans to production throughout Illinois and the acceptability of the green shell beans as a home garden vegetable. Varieties well adapted to central Illinois also were reported to thrive in other Midwestern States, but for northern Illinois, Iowa, and localities farther north the early varieties were most reliable. Cannery tests showed the feasibility of processing an acceptable product from certain varieties.

The 18 superior varieties of edible soybeans tested at Urbana, i. e., very early, Giant Green; early, 80494, Bansen, and Fuji; midseason, Illini, Hokkaido, Jogun, Willomi, 80490-1, 89162, 84979, and 87617; and late, Illington, Imperial, 87606, Funk Delicious, Emperor, and Higan, showed wide differences in earliness, duration of edible period, plant height, erectness of growth, appearance of pod, and tendency to shatter. While all yielded well, some were heavier producers than others. The yield of green shelled soybeans was about $2\frac{1}{2}$ times the yield of dry ripe beans. Those most attractive in color and size of pod and size of beans also rated very good in table quality. Analyses of the 1938 crop showed that the protein content of the 18 varieties ranged from 36.43 to 44.13 percent and the fat content from 18.05 to 22.42 percent.

Most of these varieties are suitable for use as dry beans as well as green shelled beans. For a succession of green soybeans in Illinois one variety should be selected from each group. The method of growing vegetable soybeans was about the same as for growing the field type, except that they were always planted in rows far enough apart to permit cultivation. Harvest for use as green shelled beans may begin as soon as the beans attain nearly full size and the pods appear well filled and green or yellowish green in color. Mature soybeans should be harvested promptly to avoid excessive shattering and cured properly before threshing. The station's experience indicates that if soybeans contain more than 15 percent moisture at time of threshing special handling is required to prevent spoilage.

Directions for shelling and cooking green soybeans are appended. See also an earlier note (E. S. R., 79, p. 563).

Acclimatization of soybean in the Philippines, I, P. A. RODRIGO (*Philippine Jour. Agr.*, 9 (1938), No. 3, pp. 223-252, pls. 6).—Outstanding varieties for rainy season culture in tests over nearly 5 yr. included Macoupin, Manchu, Dunfield, Hakubi, Illini, and Otama-ao strains 2 and 3 from Japan. More recent introductions of merit were Yellow Biloxi Hybrid, Head Green, American Black, and Mamloxi.

Balanced incomplete block and lattice square designs for testing yield differences among large numbers of soybean varieties, M. G. WEISS and G. M. COX. (Coop. U. S. D. A.). (*Iowa Sta. Res. Bul.* 257 (1939), pp. 289-316, fig. 1).—The features of balanced incomplete block and lattice square designs, quasi-factorial arrangements adapted to the testing of differences between large numbers of varieties, are described and their analysis and relative precision on soils of varying homogeneity illustrated by soybean variety trials.

The efficiency factor of these designs, because of confounding of variety differences with block effects, is lower than that of randomized complete block designs, yet on soil of normal variability the designs permit elimination of enough variability due to soil differences to more than offset this loss. Merits of the lattice square arrangement were demonstrated on extremely heterogeneous soil where use of the design resulted in a gain in precision of 150 percent over that of randomized complete blocks. A case in which the design on very uniform soil results in a loss of precision of 31.5 percent is also illustrated. Use of these designs is recommended in variety trials involving numerous varieties when the trials are conducted on variable soil and when differences between varieties are relatively small.

Studies in experimental technique: Selection of layout, blocks versus Latin squares, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 1, pp. 7-10).—The value of laying out field experiments so that their results may be studied by modern refinements of statistical methods is exemplified by a multiple Latin square arrangement of a test of rates of applying potassium to sugarcane.

The availability of insoluble phosphates to sugar cane, A. S. AYRES (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 1, pp. 45-56, fig. 1).—In availability to H 109 sugarcane, reverted and raw rock phosphates were found to equal calcium superphosphate in the acid, high phosphate-fixing soil used. All three forms resulted in yields 10 times those obtained in the controls. Super and reverted phosphates on limed soil resulted in larger yields than on unlimed soil. Lime without added phosphate did not result in appreciably increased growth. Addition of lime at the rate of 9 tons per acre did not affect adversely the quality of the juice. Marked differences in supplies of available phosphate did not result in differences in the percentages of phosphate in millable cane, although the tops reflected the supply of phosphate in the soil. Symptoms of phosphate deficiency in the control canes were lack of normal growth, yellowish color of the leaves, and complete absence of tillering.

The markedly higher values for phosphate (rapid chemical method) at harvest, found in soils fertilized with raw rock phosphate compared with those receiving superphosphate, were interpreted as indicating that a considerable portion of this insoluble phosphate was still present in the soil at harvest in much its original form. Under field conditions the period required for the solution and subsequent fixation of raw rock phosphate possibly would be much longer. To a lesser extent reverted phosphate was found to resist fixation.

A pictorial showing the effects of delayed weed control upon subsequent growth of sugar cane, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 1, pp. 11-15, figs. 9).—Effects of delayed weeding upon sugarcane growing in soils having specific variations in available plant foods are illustrated.

Storage of sugar beets under conditions of high humidity and low temperature, J. O. GASKILL and H. E. BREWBAKER (U. S. D. A. and Colo. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 2, pp. 109-115, figs. 4).—Sugar beet roots saved for seed production were kept during five winter storage periods with negligible loss from rotting in open crates, without coating or packing material, by maintaining the temperature of the root cellar a few degrees above freezing and the humidity near saturation, and by providing for thorough air circulation. Sugar beets stored 0, 41, 84, and 125 days in the cellar, or 125 days in an outdoor pit-silo, did not differ significantly in root weight. Gradual but statistically significant decline in sucrose percentage occurred with the longer storage periods. The sucrose loss averaged 0.04 percent per day, attributed largely to respiration. Comparison of cellar-stored and pit-siloed roots after

125 days' storage indicated equivalent behavior. The cellar storage method as described is convenient and efficient for storing small lots of sugar beet breeding strains.

Strophostyles helvola (L.) Britton, its habits and probable value on eroded areas, J. N. MARTIN. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 12 (1937), No. 1, pp. 25-35, pl. 1, fig. 1).—Trailing wild bean (*S. helvola*), an annual, propagating by seed and common throughout the Mississippi Valley and States east to the Atlantic, is remarkably resistant to heat and drought. While generally found on sandy soil, it thrives on clay soils and on eroded banks and sides of gullies. It may be of value for cover and food for birds and as a green manure and nitrogen replenisher, and on eroded waste areas. The seeds, shed soon after ripening, are hard, with impermeability due to a definite light line. In the field the seeds are made permeable by variations in temperature and probably moisture of the dormant season and germinate in May and June of the season after their production. Seed coats are easily made permeable by abrasion, and good germination may be secured at any time.

Seeds and seedlings of the taro, *Colocasia esculenta*, K. KIKUTA, L. D. WHITNEY, and G. K. PARRIS. (Hawaii Expt. Sta.). (*Amer. Jour. Bot.*, 25 (1938), No. 3, pp. 186-188, figs. 2).—The course of germination of taro seeds and the development of the seedlings are described and illustrated.

Studies on the salt requirement of tobacco, F. DE PERALTA and D. B. PAGUIRIGAN (*Philippine Jour. Agr.*, 9 (1938), No. 3, pp. 253-272, pls. 7, fig. 1).—In studying the nutrient requirement of Ilagan Sumatra tobacco, 16-day-old seedlings (from sowing) germinated in quartz sand were grown in sand and solution cultures. The most promising nutrient medium had about 0.0132 gram molecule per liter (of all salts), the salts being present in about the molecular proportions: KH_2PO_4 : $\text{Ca}(\text{NO}_3)_2$: $\text{Ca}(\text{H}_2\text{PO}_4)_2$: MgSO_4 =2:6:1:2. As usual, a trace of iron in the form of ferric phosphate or ferrous sulfate is added to the culture medium. In addition to 10 essential elements, a little boron was necessary in the nutrient medium in order for the plant to develop to full maturity. Addition of a small quantity of $\text{Ca}(\text{H}_2\text{PO}_4)_2$ to a nutrient medium containing KH_2PO_4 , $\text{Ca}(\text{NO}_3)_2$, MgSO_4 , FePO_4 and H_3BO_3 improved the nutritive value of the mixture. The plant developed vigorously in a complete nutrient medium containing nitrate nitrogen. Using ammonium sulfate as a nitrogen carrier in the absence of nitrifying bacteria greatly retarded if not inhibited plant growth.

Tobacco growing in Canada, N. A. MACRAE (*Canada Dept. Agr. Pub.* 633 (1938), pp. 45, figs. 34).—Types and varieties of tobacco; climate, soils, and fertilizers; plant beds; cultural and harvest operations; seed production; curing and fermentation; preparation of tobacco for market; and measures for control of diseases and insects affecting tobacco are discussed in this revision of a bulletin noted earlier (*El. S. R.*, 35, p. 534).

Effect of fertilizers and method of their application on nodulation, growth, and nitrogen content of hairy vetch, T. H. ROGERS and D. G. STURGE. (Ala. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 2, pp. 141-148, figs. 2).—Hairy vetch (*Vicia villosa*) produced about 20 percent less growth when superphosphate and triple superphosphate came in contact with seed inoculated with a commercial culture than when the fertilizer was mixed with the soil before planting, and made 158 percent more growth when superphosphate was mixed with soil before adding soil inoculant than when it came in contact with the soil inoculant. Growth was not reduced seriously when basic slag or equal amounts of dolomite and superphosphate were applied in contact with inoculated seed. Injury by superphosphate in contact with inoculated seed was partly reduced or counteracted by dolomite. Fertilizer or inoculation increased the nitrogen content of vetch plants; when both were used the highest percentage of ni-

trogen and the most vegetative growth were obtained. The percentage of nitrogen in plants was not affected by the method of applying fertilizers. Regardless of how fertilizer was applied, commercial inoculant was superior to soil inoculant but only slightly so without fertilizer. The ratio of tops: roots increased as the vetch grew older and was highest with treatments producing the largest vetch yields, and most of the nitrogen was in the tops. Presence of nodules on vetch roots was not a sure indication that the plants were properly inoculated.

Effects of fertilizer applications and other cultural practices on some kernel characteristics of winter wheat, J. T. SULLIVAN, H. R. KRAYBILL, C. B. GUSTAFSON, G. H. CUTLER, G. A. BRINSON, R. R. MULVEY, and G. P. WALKER (*Indiana Sta. Bul.* 432 (1938), pp. 48, figs. 2).—Numerous samples of Purkof, Michigan Amber, Purdue Nos. 1 and 3, and 21-2-11 wheat, grown in 1931-33 on fertilizer, rotation, and cultivation test plats in different locations in Indiana, were subjected to chemical, milling, baking, and other tests.

Spring applications of nitrogen fertilizers tended to increase the hardness characteristics, such as percentages of protein and of vitreous kernels, especially in wheat receiving the latest application on May 20, but did not increase significantly fermentation time, granulation number, and test weight. Nitrogen applied in autumn had very little effect on the hardness characteristics. Previous legume crops in rotation, however, tended to increase vitreousness and amount and quality of protein, as well as test weight.

Phosphorus applied alone or in mixed fertilizers increased yield and decreased vitreousness, protein content, and the loaf volume, and had small effect on granulation number. In many instances fermentation time was increased, although quantity of protein was lowered. Effects with superphosphate were more marked than with rock phosphate on limed plats, but the larger amounts of rock phosphate were more effective than superphosphate on unlimed plats.

Plats never fertilized produced wheat of low yield, shrunk grains, and relatively high protein content. Lime alone increased yield considerably, but the kernels were still small and high in protein. Complete fertilizers used with lime resulted in higher yields and wheat with lower protein content, higher kernel weight and test weight, and lower vitreousness. Clover preceding wheat in the rotation increased hardness as measured by protein content, vitreousness, and time test, while wheat preceding wheat decreased these hardness characteristics. Milling and baking tests on a limited number of samples indicated that protein content of milled fractions and, in general, loaf volumes, were correlated with protein content of wheat.

Wheat improvement in the eastern United States, B. B. BAYLES and J. W. TAYLOR. (U. S. D. A.). (*Cereal Chem.*, 16 (1939), No. 2, pp. 208-223, fig. 1).—The distribution of wheat varieties in the eastern United States is indicated, with discussion of losses due to winter-killing, hessian fly, lodging, leaf and stem rust, loose smut, bunt, and other diseases, and the possibility of reducing these losses through plant breeding.

The technic of producing a new soft wheat, W. W. WORZELLA. (Ind. Expt. Sta.). (*Cereal Chem.*, 16 (1939), No. 2, pp. 188-194, figs. 4).—Objectives and features of field and laboratory methods in wheat improvement are described.

Seed impermeability and viability of native and introduced species of Leguminosae, M. EL-J. HUTTON and R. H. PORTER. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 12 (1937), No. 1, pp. 5-24, figs. 3).—Seeds of *Lespedeza virginica* and *Robinia pseudacacia* were not changed significantly in impermeability by laboratory storage for 2 yr. That in seeds of *L. capitata*, *Strophostyles helvola*, and soybeans declined significantly and usually with a reduction in the percentage of normal seedlings. Impermeability of *S. helvola* was correlated

directly with moisture content of the seed, increasing rapidly when the moisture content fell below 21 percent. Shaking in a glass bottle for 10 min practically eliminated impermeability in seeds of *L. capitata*, *L. virginica*, *Amorpha fruticosa*, *R. pseudacacia*, and soybeans, with resultant development of normal seedlings. The shaking caused fissures to develop at the base of the hilum in seeds of *A. fruticosa* and *L. capitata* through which water entered the embryo, with consequent germination. The bibliography includes 41 references.

Scarification studies on southern grass seeds, G. W. BURTON. (U. S. D. A. and Ga. and Ga. Coastal Plain Expt. Stas.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 3, pp. 179-187, fig. 1).—Removal of the paleas, treatment of seed in concentrated technical H_2SO_4 for 5 min., and removal of all glumes from the caryopses by rubbing the seeds between sandpaper blocks, all hastened germination of Bahia grass (*Paspalum notatum*) seed materially. Seed treated 10 min. in concentrated technical H_2SO_4 germinated 52 percent in 8 days and untreated seed 0.3 percent in 3 weeks. Scarification with crude sulfuric acid (used in making superphosphate) for from 45 to 60 min. proved about as effective as a 10-min. scarification in concentrated technical H_2SO_4 , was much cheaper than technical acid, and there was less danger of killing seed by overtreatment. Indications were that the optimum treatment for one lot of seed may be injurious for another lot. The wisdom of making several small preliminary treatments before treating large quantities of seed is evident. Treatments of 70° C. dry heat for 4 hr., soaking in water 24 hr. with and without reduced pressure, and with concentrated HCl for 5 min. did not increase the germination significantly. Bahia grass seed, unlike many grasses, seemed to require no rest period.

Scarifying Dallis grass (*P. dilatatum*) seed with concentrated technical H_2SO_4 for 5 min. hastened germination materially. The value of 35 percent NaOH as a mild scarifying agent was demonstrated. Five- and 10-min. treatments with either 50 percent HCl or 35 percent NaOH increased the germination rate of centipede grass (*Eremochloa ophiuroides*) seed. Germination of unhulled seed of Bermuda grass was hastened by treatment with concentrated HCl for 5 min. Seed of Vasey grass (*P. urvillei*) and carpet grass (*Axonopus affinis*) germinated readily without treatment, and all scarification treatments reduced the viability of the seed of these species.

A machine facilitating acid scarification of rather large quantities of seed is described.

Pennsylvania weeds, E. M. GRESS (*Pa. Dept. Agr. Bul.* 558 (1938), pp. 39, figs. 17).—A revision of the publication noted earlier (E. S. R., 55, p. 740).

Effectiveness of contact sprays in the control of annual weeds in cereal crops, B. N. SINGH and K. DAS (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 3, pp. 200-208).—In replicated experiments on control of annual weeds (E. S. R., 80, p. 481) in wheat by sulfuric acid, ammonium thiocyanate, and copper sulfate sprays, degree of control differed with weeds and herbicides. *Anagallis arvensis* and *Euphorbia dracunculoides* were killed out more than *Chenopodium album*, explainable on morphological peculiarities and the relative hardness of the weeds and quantity of spray solution adhering on the surface. The herbicides were effective in the decreasing order mentioned. Factors apparently contributing to the effectiveness of treatment were concentration of the herbicides, time of application, stage and development of the plants, leaf area exposed, and temperature and humidity of the atmosphere. Grain yield tended to increase with a reduction in weed density. Spraying with a higher concentration of ammonium thiocyanate solution gave better results due to addition of extra nutrients besides elimination of weed competition. Sulfuric acid spraying did not have a significant souring effect on the soil.

The control of nut grass with chloropicrin, G. H. GODFREY. (Tex. Expt. Sta.). (*Soil Sci.*, 47 (1939), No. 5, pp. 391-395, pl. 1).—Treatment of infested soil at Weslaco, Tex., with chloropicrin at rates of from 400 to 750 lb. per acre, covering with mulch or Kraft paper or wet soil, gave practical control of nut-grass (*Cyperus rotundus*). Cost per 100 sq. ft. approximated \$1 for chloropicrin and a few cents for gas-proof paper for cover. This method is deemed practicable for small gardens, flower beds, and small infestations, but probably will be too expensive on large-scale field application, where the tillage method of Smith and Mayton (El. S. R., 79, p. 190) is suggested. Since chloropicrin is deadly to plant life it must not be applied in the vicinity of living shrubs or trees in garden or flower beds. Its lethal effects on injurious insects, nematodes, fungi, etc., have been noted (El. S. R., 73, pp. 57, 201; 75, p. 638).

HORTICULTURE

[Horticultural studies by the Alaska Station, 1937] (*Alaska Sta. Bul.* 7 [1938], pp. 18, 19, 26, 27, 30, 31, 33-35).—Among studies the progress of which is discussed are the selection and propagation of native blueberries, currants, and raspberries; testing of small fruit varieties; propagation of ornamentals; and varieties of canning peas and other garden vegetables, annual flowers, and other plants.

[Horticulture at the Georgia Coastal Plain Station, 1937] (*Georgia Coastal Plain Sta. Bul.* 29 (1938), pp. 32, 80, 84-92, 93-115, 132-137, figs. 2).—Herein are presented progress statements on variety tests with tomatoes, watermelons, snap beans, asparagus, sweet corn, lettuce, and other vegetables, peaches, grapes, figs, strawberries, jujubes, blueberries, and citrus and other fruits; fertilizer studies with tomatoes, watermelons, lima beans, cabbage, and lettuce; cultural studies with tomatoes and lima beans; and adaptability tests with tung-oil trees, chia, and perilla.

[Vegetable and flower variety trials, 1935-38], W. B. MACK, E. M. RAHN, G. J. STOUT, F. W. HALLER, E. I. WILDE, O. E. HOXSIE, and L. M. STEINITZ (*Pennsylvania Sta., Jour. Ser. Papers* 799 (1937), pp. [11], figs. 2; 802, pp. [11]; 803, pp. [12]; 806, pp. [11]; 816 (1938), pp. [14], figs. 63; 821, pp. [7]; 822, pp. [9]; 825, pp. [23]; 870, pp. [11]; figs. 59; 871, pp. [7]; 872, pp. 8; 875, pp. [33]; 877, pp. 7; 879, pp. 7; 881, pp. 4; 882, pp. 5; 885 (1939), pp. 9).—Herein are included mimeographs on the following subjects: Celery, 1937, beets and carrots, 1936-37; cabbage, 1936-37; sweet corn, 1937; peas, 1937; beans, 1937; peppers, 1935-37; petunias, 1937; peas, 1938; beets, carrots, onions, and radish, 1938; petunias, 1938; tomatoes, 1938; cabbage and cauliflower, 1938; beans, 1938; peppers, eggplant, and summer squash, 1938; and sweet corn, 1938.

[Horticultural investigations by the Western Washington Station], C. D. SCHWARTZ, G. A. HUBER, and W. J. CLORE. (Partly coop. Wash. Expt. Sta. and U. S. D. A.). (*Western Washington Sta. Rpt.* 1938, pp. 25-27).—Brief comments are offered on the progress of investigations in raspberry, blackberry, and strawberry breeding; varieties of vegetables for freezing preservation; and varieties of fruits and nuts.

Snap bean production in South Carolina, J. M. JENKINS, JR. (*South Carolina Sta. Cir.* 59 (1939), pp. 16, figs. 5).—Consisting for the most part of general information relating to the extent of the industry, varieties, cultural requirements, fertilizers, control of insects and diseases, and harvesting, certain data are included that show that the use of 30 lb. of available N, 100 lb. of available phosphoric acid, and no K has given the most profitable yields. The use of from 50 to 100 lb. of available K significantly reduced the yields as compared with no K. The harmful effect of K is ascribed to an accumulation from several

years of intensive fertilization. Fertilizers having all the N in water-soluble form gave as good yields as those in which from 20 to 50 percent of the N was in water-insoluble form. The need of including Mn and Mg in the mineral fertilizer is stressed.

Directions for spraying fruits in Illinois, W. P. FLINT and H. W. ANDERSON (*Illinois Sta. Cir. 492 (1939), pp. 32, figs. 6*).—General information is presented.

Fall fertilization of peach trees in the Sandhills, C. F. WILLIAMS (*North Carolina Sta. Bul. 321 (1939), pp. 15, figs. 3*).—Based on studies with bearing and young trees it was found that N from nitrate of soda was assimilated by the roots of peach trees during the dormant season if the temperatures were above freezing, but was not translocated to the above-ground parts unless temperatures were above 45° F. Although nitrate applied to bearing trees in November and December produced a response in growth and yield approximately equal to the same rates of application in March, reserves in the tree were not increased before February unless the nitrate was applied in August or October. Longer terminal growth and larger yields resulted if the trees went into the dormant period in relatively high N condition, but fewer buds per shoot resulted unless the trees also had an application of N in March. The data suggested the need of good nutritional conditions throughout the season rather than heavy fertilization at any one time. Available nutrients were as important after the period of length growth and harvest in creating food reserves in the trees as they were in early spring for producing length growth. Postharvest applications of nitrate did not encourage late growth but did tend to avoid premature dormancy and thereby increased the resistance of the trees to winter injury. Postharvest applications of nitrate provided N for the winter period, but a fertilizer program including more slowly available materials applied in spring and early summer should be just as effective under most conditions. The use of cover crops is suggested as a means of providing a more constant supply of nutrients.

Nitrogen fertilization of bearing Elberta peach trees in the Sandhills, C. F. WILLIAMS (*North Carolina Sta. Bul. 322 (1939), pp. 24, figs. 4*).—To Elberta trees 8 yr. old at the beginning of the 5-yr. study and uniformly treated with respect to P and K and growing on a sandy soil containing little humus and low in native fertility and moisture-holding capacity, N in the form of nitrate of soda was applied in different amounts at different seasons and in single and split applications. During the 5-yr. experiment yields decreased each year on all treatments, and after the second year were unsatisfactory. In the first season, increases in the rate of nitrate application increased yields, but after the initial year the differences in yield between 3 and 6 lb. of nitrate per tree were small. The first year yields and growth increased with earliness of applications, but in the succeeding years the highest yields were often secured with treatments including an application after harvest. Apparently, postharvest treatments tended to delay leaf fall and dormancy and thus decreased the response of the trees to warm weather during the winter. Postharvest applications resulted in a high nutritive condition during the fall and winter and resulted in greater terminal growth the following year. Differential N treatments affected the rate of terminal growth but not at the time of its occurrence. There was no effect of the different treatments on the time of bloom. Increasing the total amount of nitrate applied before harvest tended to delay fruit maturity. Winter injury occurred only in trees of an extremely low nutritive condition. On the whole, it appeared that a more or less constant supply of nutrients was more desirable than heavy N fertilization at any one time.

Orchard and forest trees (*Nebraska Sta. Cir. 60 (1939), pp. 39-43, figs. 2*).—The station work with tree fruits and windbreaks is briefly reviewed.

Blueberry culture in Massachusetts, J. S. BAILEY, H. J. FRANKLIN, and J. L. KELLEY (*Massachusetts Sta. Bul. 358 (1939), pp. 20, figs. 12*).—For the most part this includes general information on cultural requirements, propagation, pruning, control of insects and diseases, harvesting and marketing, etc. Studies in the improvement of wild high-bush varieties showed that the removal of competing trees and vegetation increased the growth of blueberry bushes. Pruning, where not excessive, increased growth and yields. Fertilizers, particularly N, increased growth and yields, the latter mostly from an increased number of fruits per plant. Fertilized bushes showed a marked tendency to annual bearing, and the berries on fertilized plats were firmer during dry periods. A combination of fertilization and pruning was much more effective than either alone. Any treatment that increased terminal shoot growth up to about 10 in. increased yield. Above 10 in. the growth tended to become overvegetative.

FORESTRY

A method of marking trees, J. D. CURTIS. (Mass. State Col.). (*Jour. Forestry, 37 (1939), No. 3, pp. 246-249, figs. 3*).—The author discusses the use of wooden nails made of bamboo or other material for marking trees.

Measurement of precipitation above forest canopies, W. E. DAVIS. (U. S. D. A.). (*Jour. Forestry, 37 (1939), No. 4, pp. 324-329, figs. 4*).—Stating that the amount of precipitation intercepted by forest canopies has been estimated by various investigators to be from one-fifth to one-third of the total rainfall, the author presents a method for measuring the rainfall at the tree crown surfaces. By the use of a simple hoist device mounted at the end of a pole the gage could be raised or lowered from the ground to the crown-surface position.

Transpiration of trees and forests, L. S. MINCKLER. (U. S. D. A.). (*Jour. Forestry, 37 (1939), No. 4, pp. 336-339*).—Based on measurements on large forest trees growing in their natural habitat in New York State, transpiration in acre-inches is estimated to range from 4.72 to 17.02 for red maple, from 1.52 to 7.37 for American elm, and from 2.35 to 7.87 for white pine. Sugar maple and beech lost 3.04 and 2.98 acre-in., respectively. Current transpiration is influenced by light intensity, relative humidity, time of day, and season.

Density of stocking and character of ground cover as factors in longleaf pine reproduction, L. J. PESSIN. (U. S. D. A.). (*Jour. Forestry, 37 (1939), No. 3, pp. 255-258, figs. 2*).—In a dense natural stand of 12-year-old longleaf pine seedlings still in the grass, plats denuded in 1932 of all vegetation except the pine showed greater height development in the next 5 yr., regardless of the density of the stand, than where the grass was not removed. In the grassy plats the maximum growth occurred in the plat with 1,000 seedlings per acre, but height growth was only one-third that of the denuded area. The favorable effect of grass removal is believed to result from release from root competition for nutrients and at times for water.

The release of seeds from jack pine cones, R. K. LeBARRON and F. H. EYRE. (U. S. D. A. and Univ. Minn.). (*Jour. Forestry, 37 (1939), No. 4, pp. 305-309, figs. 3*).—Having shown in an earlier report (E. S. R., 80, p. 777) that mid-summer heat is a potent factor in releasing seed from cone-bearing slash, the authors compared the amount and time of seed fall from jack pine cones attached to slash, felled trees, and girdled trees. During a period of 29 mo., the cones of the lopped branches yielded 9 times as many seeds as the felled trees and 100 times as many as the girdled trees. The slash cones released

25, 68, and 7 percent of the seed, respectively, in the first, second, and third years. The girdled and the felled trees released practically no seed the first year. July and August were the months of maximum release each year, with smaller amounts released in June, September, and October.

Testing germination in sand, A. A. DUNLAP and A. D. McDONNELL. (Conn [New Haven] Expt. Sta.). (*Jour. Forestry*, 37 (1939), No. 4, pp. 330-332, fig. 1).—A method which involves the use of partially sterile sand continuously supplied with moisture by subirrigation is described. With the device there were secured germination percentages of forest seeds practically equal to or higher than those obtained in soil or in oven germinators. In addition, there was less tendency to decay.

The phosphate and potash starvation of forest seedlings as a result of the shallow application of organic matter, S. A. WILDE and R. WITENKAMP (*Jour. Forestry*, 37 (1939), No. 4, pp. 333-335, figs. 3).—Evidence is presented to show that top dressings of organic matter discourage the downward movement of the roots, thereby preventing their securing adequate supplies of other nutrients, chiefly phosphate and K, occurring in the soil at greater depths. In field practice it is suggested that prior to planting the seed or seedlings a considerable portion of the peat or duff should be incorporated in the soil by alternate plowing and disking or rototilling.

Relation of the root system of a sprouting stump in *Quercus montana* Willd. to that of an undisturbed tree, O. M. WOOD. (U. S. D. A. et al.). (*Jour. Forestry*, 37 (1939), No. 4, pp. 309-312, fig. 1).—In studies conducted in an experimental forest in the New Jersey Coastal Plain, excavation of the roots of two trees, one dug directly and the other in September of the season following cutting, indicated that a portion of the root system dies shortly after the parent tree is cut. The sprouts developing in the year following cutting had a leaf area of about 13 percent of that of the parent tree.

The effect of spacing on the growth of Norway pine plantations—a progress report, D. D. STEVENSON and R. A. BARROO. (Pa. Expt. Sta.). (*Jour. Forestry*, 37 (1939), No. 4, pp. 313-319, fig. 1).—Observations on the development of Norway pines planted in the spring of 1921 at intervals of 5 by 5, 6 by 6, 6 by 8, and 10 by 10 ft. showed in 1937 that crown closure had occurred on all but the 10- by 10-ft. plat. Natural pruning up to a height of 8 ft. had occurred on the 5- by 5-ft. plat, with practically none on the 10 by 10. On the 10 by 10 trees branch diameters were over 50 percent larger than on the more closely planted, had made the most rapid growth during the 17 yr., and were the tallest, with little difference in height between the trees on the other three plats. The average form quotient of the 10 by 10 trees was considerably lower than that of the other trees.

A design for experiments in thinning forest stands, J. G. OSBORNE. (U. S. D. A.). (*Jour. Forestry*, 37 (1939), No. 4, pp. 296-304, fig. 1).—This paper presents with discussion and elaboration an experimental design which is intended to increase the amount and accuracy of information obtained from thinning investigations.

An experiment in the use of sodium arsenite in thinning ponderosa pine, B. R. LEXEN. (U. S. D. A. and Univ. Ariz.). (*Jour. Forestry*, 37 (1939), No. 3, pp. 259-262).—The injection of sodium arsenite solution into holes bored into the trunks of ponderosa pines was found effective in killing the trees. In the case of over 700 trees ranging from 4 to 18 in. in diameter poisoned over a period of 3 yr., in no instance did bark beetles enter the cambium. Common wood borers entered the year following poisoning but preferred areas not reached by the ascending arsenite of soda.

Hardwood brush disposal in the Hudson highlands, H. H. TRYON (*Black Rock Forest Papers, 1 (1938), No. 12, pp. 81-86, figs. 4*).—Of four methods of handling brush, lopping and scattering was the most effective for hastening decay but interfered with the hauling of wood from the forest. Large piles of brush were observed to be slow to decay except at the ground level. The most efficient procedure was to make small shallow piles, none over 2.5 ft. high. After two summers such piles were usually so well rotted that the fire hazard was materially reduced. Practical suggestions are included.

Forest fires in Ohio, 1923 to 1935, B. E. LEESE (*Ohio Sta. Bul. 598 (1938), pp. 54, figs. 21*).—Information is presented on the location and organization of the forest fire districts, number and size of fires, damage caused, cost of suppression, causes of fires, etc.

DISEASES OF PLANTS

The Plant Disease Reporter, May 1 and 15, 1939 (U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 23 (1939), Nos. 8, pp. 129-139; 9, pp. 141-157, figs. 4).—The following are included:

No. 8.—Noteworthy Florida and Georgia fungi, by V. K. Charles; notes on the occurrence of *Coleosporium crowellii* Cummins in the United States, by G. G. Hedgecock; notes on *Coleosporium crowellii*, by J. Dearnness; further reports on apple scab, for Massachusetts, Rhode Island, and New York (Hudson Valley); some reports on diseases of cereals, including rusts in Texas and powdery mildew on barley in California; *Macrophomina phaseoli* on *Strophostyles helvola* in Georgia, by H. W. Johnson; and brief notes on dodder on tomato in Texas, drop of lettuce and other lettuce diseases in North Carolina, and tobacco downy mildew appears in Virginia.

No. 9.—Relative prevalence and geographic distribution of various ear rot fungi in the 1938 corn crop, by P. E. Hoppe; early appearance of crown rust of oats in Arkansas in 1939, by H. R. Rosen; rusts and loose smut on small grains in Texas, wheat leaf rust in Kansas, wheat leaf rust in Iowa, and leaf rust on wheat and barley in Kentucky; apple scab development in Rhode Island, New York, Delaware, and Illinois; some reports on diseases of peach, including the general prevalence of scab infection on peach twigs, scab on peach twigs in New York, brown rot and frost injury in Delaware, and peach leaf curl in Illinois; red stele of strawberry in Kentucky, pear scab in New York, development of cedar rusts in New York, and blight injury to pears from last year in New York; reports on tobacco diseases, including tobacco downy mildew in Virginia, downy mildew and wildfire in Maryland, and tobacco diseases in Kentucky; late blight of potato on the Eastern Shore of Virginia, by H. T. Cook; and *Ceratostomella (Endoconidiophora)* on planetrees, by M. E. Fowler.

[Plant disease studies by the Georgia Coastal Plain Station]. (Partly coop. U. S. D. A.). (*Georgia Coastal Plain Sta. Bul. 29 (1938), pp. 10, 11, 92, 93, 115-119, 125-130, figs. 3*).—Brief reports on the following are included: Control of root knot nematode on tobacco and other crop plants by nematocides, resistant sorts, and cultural practices; tomato disease studies with special reference to *Macrosporium*; and tobacco diseases, including downy mildew control by spraying and cultural practices, damping-off (*Rhizoctonia* and *Pythium*), sore shin (*Sclerotium rolfsii* and *Rhizoctonia* sp.), frog-eye leaf spot (*Cercospora nicotianae*), Granville bacterial wilt, *Fusarium* wilt, black shank (*Phytophthora parasitica nicotianae*), and mosaic.

Department of plant pathology (Western Washington Sta. Rpt. 1938, pp. 27-32).—Brief reports of studies are included with reference to bulb diseases, by

G. A. Huber;^{*} brown rot of stone fruits, and raspberry mosaic and its vectors (El. S. R., 78, p. 210; 80, p. 504), both by Huber and K. Baur; crown gall of blackberry, by Baur and Huber; stem rot (*Botrytis*-type organism) of poinsettia, by Huber; bronzing and dwarfing of hops, alfalfa bronze top, raspberry rust, crumbly fruit in raspberries, and black tip of rhubarb, all by Baur and Huber; canker and gall disease of gardenia, by Huber; late blight of potato, by Huber and Bauer; and club root of crucifers, by Baur and Huber.

Infection of tomato and red clover with conidia of *Pleospora lycopersici* and *Macrosporium sarcinaeforme*, J. T. MIDDLETON. (Univ. Calif. and Univ. Mo.). (*Phytopathology*, 29 (1939), No. 6, pp. 541-545, figs. 2).—On inoculation, conidia of *P. lycopersici* were found capable of infecting leaves and flowers of tomato, while negative results were obtained on red clover, white clover, alsike, alfalfa, and white sweetclover. On the other hand, conidia of *M. sarcinaeforme* proved capable of infecting various leguminous plants on inoculation, but no infection was obtained on tomato. Differences in the cultural characters as well as in the pathogenic powers of these two fungi are considered prohibitive to the application of the binomial *M. sarcinaeforme* to the imperfect stage of *P. lycopersici*.

Plant viruses, I, II (*Tab. Biol.*, 16 (1938), No. 4, pp. 355-371, figs. 4; 17 (1939), No. 1, pp. 24-71).—Two papers are included:

I. *Serological, chemical, and physico-chemical properties*, F. C. Bawden and N. W. Pirie.—This is a conspectus of present knowledge, with tabulations, and virus groupings according to various properties.

II. *Virus diseases of plants*, K. M. Smith.—This is an annotated tabular list of plant viruses alphabetically arranged by hosts, with insect vectors and other transmission methods, differential hosts, chief symptoms, main host plants, distribution, control, and literature references indicated for each. There is also a general bibliography.

The intracellular inclusions of some plant virus diseases, F. C. BAWDEN and F. M. L. SHEFFIELD (*Ann. Appl. Biol.*, 26 (1939), No. 1, pp. 102-115, pls. 2).—"The contents of healthy cells and those infected with a number of different plant viruses are described. Some of these viruses apparently do not cause the production of intracellular inclusions; others cause the production of amorphous bodies only, and the remainder produce both amorphous and crystalline inclusions. The properties of the inclusions are compared with those of purified preparations of the viruses. It is shown that insoluble complexes of the viruses with protamines, histones, and proteins which in many ways resemble the intracellular inclusions can be produced in vitro. Possible explanations for the formation and disappearance of the inclusions in infected plants are suggested."

Transmission of plant viruses by insects, H. H. STOREY (*Bot. Rev.*, 5 (1939), No. 4, pp. 240-272).—Following an introductory discussion, this critical review (90 references) of transmission by leaf-sucking insects treats the subject matter under the headings: How the vector obtains the virus, how the vector carries the virus (with transmission negative on first hosts and positive on succeeding hosts, and the reverse), and how the vector inoculates the virus.

Injuries to plants caused by insect toxins, W. CARTER. (Hawaii Pineapple Producers' Expt. Sta.). (*Bot. Rev.*, 5 (1939), No. 5, pp. 273-326).—This comprehensive review (257 references) concerns those plant toxemias induced by insect secretions toxic to the plant cell but not increasing within plant tissues and distinct from damage arising from traumatic injury incident to insect feeding. Except for the gall formers, which include species in several

^{*} Florists' Rev., 79 (1937), No. 2045, p. 21.

orders, all the forms referred to here are sucking insects belonging to the Homoptera or Hemiptera. The voluminous data are discussed under leaf-spotting forms, toxic effects of feeding by Miridae (Capsidae), tissue derangements by the Aphididae, insect galls, hopperburn, froghopper blight, psyllid yellows of potato and tomato, and mealybug wilt of pineapples.

Physiological relations between host and parasite in crown gall: An example of basic biological research with plant materials, A. J. RIKER. (Wis. Expt. Sta.). (*Amer. Jour. Bot.*, 26 (1939), No. 3, pp. 159-162, figs. 3).—The author enumerates the advantages of plants over animals as objects for basic research on cellular pathology, and summarizes the high points, particularly of his own studies directed towards determining the mechanisms whereby bacteria stimulate the infected plant to hypertrophy and hyperplasia. His discussion of the crown gall topic is considered under its bacteriological, biochemical, and physiological aspects, and both factual and theoretical data are included.

Some factors affecting the susceptibility of plants to fire blight, H. E. THOMAS and P. A. ARK (*Hilgardia [California Sta.]*, 12 (1939), No. 4, pp. 299-322, figs. 2).—Histological observations on shoots of resistant v. susceptible plants in general supported earlier workers in indicating that the size of intercellular spaces is a minor factor in determining the course of infection. Tissues known to be high in N were in general more susceptible than the nearest comparable tissues of lower N content. The evidence suggests that the concentration of solutes in the nectar and perhaps also in the plant sap as affected by atmospheric humidity is important in the penetration by *Bacillus amylovorus* (= *Erwinia amylovora*) and in the development of infection. On the trunks of girdled pear and apple trees, the bark immediately above proved more susceptible than that immediately below. Slight wounds 2-4 in. below the points of inoculation of susceptible shoots failed to cause marked change in the development of infection. Gums and suberins were not detected at the margins of wounds until after the period during which the wounds would be susceptible. Etiolation had a relatively slight influence on infection, while defoliation definitely reduced susceptibility. In the progeny of a hybrid of *Pyracantha angustifolia* and *P. gibbsii yunnanensis*, resistance seemed to be at least partially dominant. In the F₂ generation no relation was observed between susceptibility and parental resemblance. Forty-four references are included.

Studies on variation in *Gibberella saubinetii* (Mont.) Sacc. (Fusarium Graminearum Schwabe), M. GODDARD (*Ann. Missouri Bot. Gard.*, 26 (1939), No. 2, pp. 99-164, pls. 8, figs. 2).—After growing a number of conidial isolates of two strains for several generations on potato-dextrose agar, only one permanent variant was formed in one strain and two in the other. When nine conidial isolates, including the three variants, were grown on Brown's, Coons', Richards', Leonian's and potato-dextrose agar at 18°, 20°, 25°, and 30° C., ecovariants, as well as some permanent variations, were produced. More variations of both kinds and best growth occurred at the lower temperatures and on Leonian's agar. Optimum temperature was 25°. Subjected to variations in media and temperature, mycelial and conidial forms were only fairly constant. The pionnotal stage in one strain reverted to the aerial mycelial stage, which seemed to answer the description of the original ascospore isolate from corn stubble. It completed a cycle of growth by passing from the aerial mycelial phase through the conidial and appressed phase, through the pionnotal phase back to the aerial mycelial phase. No new or intermediate strains resulted from crossing morphologically different strains. There was no evidence of caryogamy in the hyphal anastomoses. Production of two sectors at about

the same time and identical mutant sectors favor the theory that the saltation was somatic rather than germinal. Nearly four pages of bibliography are included.

Distribution and prevalence of Ozonium root rot in the shelterbelt planting area of Oklahoma. G. L. PELTIER, F. R. SCHROEDER, and E. WRIGHT. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 6, pp. 485-490, figs. 3).—Using methods previously described (E. S. R., 77, p. 345), the authors found that the western limit of *Phymatotrichum omnivorum* root rot infestation extends somewhat beyond the 99° meridian, the northern limit just south of the Wichita Mountains, the eastern limit beyond the planting area, and the southern limit across the Red River into Texas. A relationship appeared to exist between infested areas and certain watersheds and drainage basins of the larger rivers. Since much of the success of tree planting in the Southwest depends on the previous location of root rot-infested areas, the U. S. D. A. Forest Service can, on the basis of the information obtained, now safely make shelterbelt plantings either by avoiding infested lands or by using resistant tree species on infested soil.

Unusual features in the behavior of sclerotia of *Phymatotrichum omnivorum*. J. T. PRESLEY. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 6, pp. 498-502, figs. 2).—After reviewing briefly the previously known stages (vegetative, sclerotial, and conidial) of the fungus, the author reports that, in contrast to the usual development of reproductive structures from primordia located just beneath the rind of sclerotia, in the *Phymatotrichum* sclerotium every cell seems capable of reproduction. However, these cells have never been seen to germinate and give rise to reproductive structures. Instead, a sterile mycelium is produced by "vegetative sprouting," which continues as long as any part of the sclerotium remains viable. Detailed study indicated that the new hyphae do not arise as branches or elongations of the resting cells, but appear to be formed within the cells, whose contents appear to go through a process of disorganization and reorganization that results in the forming of new hyphae instead of sporophores. Each of these new hyphae is capable of developing into a mycelium. The sequence of events within the sclerotial cells, based on the material thus far observed, is described and illustrated in detail, but final conclusions as to their significance is reserved pending further cytological studies under way.

Studies of monosporous cultures of *Septoria bromigena*. J. L. ALLISON. (Minn. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 6, pp. 554-556, fig. 1).—This is a preliminary report of studies of 200 monosporous lines of *S. bromigena* isolated (1937) from *Bromus inermis* collected in 4 Minnesota localities and grown on 12 culture media. Among them there were many consistently different cultural types falling into 4 groups corresponding to the locality from which isolated. The isolates from each locality differed from those of every other locality, while those from the same locality, though differing slightly, were very much alike. Sector variants appeared in some cultures of all lines, several distinct variants often developing in a single culture. Inoculated on susceptible strains of *B. inermis*, infection was obtained readily with conidial suspensions but none with macerated mycelial mat suspensions of 6 nonsporulating variants. Preliminary evidence indicates that *B. inermis* is the only susceptible one of 34 *Bromus* species tested, and that inbred lines of this species differ greatly in susceptibility.

Soil infestation by *Ophiobolus graminis* and its spread. H. FELLOWS and C. H. FICKE. (U. S. D. A. and Kans. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 7, pp. 505-519, fig. 1).—The data presented from field and greenhouse tests indicate that any agency capable of moving soil particles or plant debris may

carry infestation, but that the establishment of take-all in a new location is slow and uncertain. *O. graminis* did not spread from infested to noninfested soils when such soils were placed in contact without mixing and no wheat roots were growing through the adjacent sections, but when roots grew through these sections in either direction the fungus spread to the noninfested soil. Infested soils placed in contact with noninfested soils often lost their infestation, and infestation often apparently disappeared from take-all spots in the field. Dead diseased host remains proved to be fairly good carriers in the greenhouse but not in the field. Ascospores were an excellent source of infection, but were seldom seen in the Middle West. Cultures of the fungus grown on sterilized barley-oat medium experimentally infested the soil in both field and greenhouse, and the soils remained infested a long time, but methods of soil infestation were more positive in greenhouse than in field tests. Infected roots of the living host are considered perhaps the most positive factor in carrying *O. graminis* to non-infested soil and in contributing greatly to its establishment. This explains the value of crop rotation in controlling take-all.

Summary of uniform spring-wheat bunt nursery, 1938, H. A. RODENHISE and J. A. CLARK (U. S. Dept. Agr., Bur. Plant Indus., 1939, pp. 3).—This is a discussion and tabulation of the results obtained in 1938, together with averages for previous years.

Studies of the susceptibility of forage grasses to cereal smut fungi.—II, A preliminary report on *Ustilago hordei* and *U. nigra*, G. W. FISCHER. (U. S. D. A. and Wash. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 6, pp. 490-494).—Three collections of a covered smut from *Agropyron cristatum* and *Elymus glaucus jepsoni*, morphologically identical to *U. hordei*, were inoculated into Beldi Giant and Trebi barley, along with one authentic collection of *U. hordei* from Beldi Giant. Monosporidial cultures of these collections were also crossed in all possible combinations and inoculated into the two barleys. Both varieties became smutted by each of the three grass collections of *U. hordei*, by the collection from Beldi Giant, and by all crosses among the collections. The collections on *Agropyron* and *Elymus* are therefore considered to be *U. hordei*. Of 25 species of grasses in the tribe Hordeae inoculated with the same 4 collections of *U. hordei*, 10-50 percent infection resulted on *A. caninum*, *E. canadensis*, *E. glaucus jepsoni*, *E. sibiricus*, *Hordeum nodosum*, and *Sitanion jubatum*. When the same 25 grasses were inoculated with *U. nigra*, 30-50 percent smut appeared on *E. canadensis*, *H. nodosum*, and *S. jubatum*. See also a previous note (E. S. R., 77, p. 639).

The Ustilaginales or smuts of Utah, A. O. GARRETT (Utah Univ. Bul., 29 (1939), No. 9, pp. 23, pls. 4).—This study, begun in 1902, is based on collections in the State—all by the author unless otherwise stated. It is presented as an annotated list, with a key to the genera and indexes to scientific names of both hosts and smut fungi.

Genetic and environmental factors affecting growth types of *Ustilago zeae*, M. F. KERNKAMP. (Minn. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 6, pp. 473-484, figs. 2).—A (1) strict sporidial type, a (2) rather strict mycelial type, and (3) various intermediate types of growth were shown to exist. The first type could not be induced to develop mycelium by any of the means used, while the second type could be induced to form only a very few sporidia under certain conditions. Some of the intermediate types could be induced to become either sporidial or mycelial with proper environal relations. Increasing the amount of various nutrients in solutions, especially certain sugars, increased the sporidial growth in intermediate lines and to a much lesser extent in mycelial lines. Fresh supplies of nutrients increased the

sporidial growth in intermediate lines and to a much lesser extent in rather strict mycelial lines. Temperature, pH of the medium, and "staling" products had no effect on the growth types of the lines studied. In a sporidial \times mycelial cross, segregation of factors for sporidial and mycelial growth types occurred on individual promycelia on a 4:0, 3:1, and 2:2 basis. The results appear to indicate two or more factors for both sporidial and mycelial types.

Dissemination of celery blight pathogens on the clothing of farm laborers, M. B. LINN. (Cornell Univ.). (*Phytopathology*, 29 (1939), No. 6, pp. 553, 554).—Observational and experimental evidence (1937) that spores of early and late blight due, respectively, to *Cercospora apii* and *Septoria apii* are disseminated on the clothing emphasizes the danger of walking through or cultivating celery fields when the plants are wet. Reported failures of some growers with fungicidal control practices may possibly be explained by these findings.

A survey of the spotted wilt disease of lettuce in the Salinas Valley, M. R. HARRIS (Calif. Dept. Agr. Bul., 28 (1939), No. 3, pp. 201-213, figs. 2).—The disease is described and its virus nature discussed. It is reported as having been noted on 43 species of 15 families (listed). The symptoms on hosts other than lettuce are also described, and various hosts are grouped according to relative susceptibility. A total of 44,924 acres of lettuce were planted in the Salinas Valley in 1938, and a summary of the amount of infection at various times during the year, the distribution of hosts, and the prevalence of spotted wilt on lettuce there are considered. As a result of this survey, the following suggestions are presented: Lettuce fields should be plowed or disked as soon as harvested, ornamental hosts in the vicinity should be eliminated, so far as practicable lettuce should be avoided in appreciably infected areas, lettuce should not be planted near pepper or tomato if it is to be harvested late in summer or fall, nor should it be planted in summer or fall on areas adjacent to ornamental hosts used for seed production, and old malva plants should be destroyed in cultivated areas and along roadsides. Thirteen references are given.

Chemical elimination of saprophytes during laboratory germination of seed peas, W. CROSBIE and S. PATRICK. (N. Y. State Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 6, pp. 397-422).—Of the various chemicals tested, dusts containing mercury compounds effectively controlled surface molds on pea seeds when properly used and without injury to the seedlings. The size and weight of the seedlings and the germination percentages were increased by Ceresan treatment. Copper and zinc compounds were less efficient fungicides and prevented normal radicle elongation. Sulfur, aldehydes, and ferrous sulfate failed to reduce the fungus-seed associations. Dip treatments with soluble mercury compounds eliminated molds as effectively as the dusts and gave a saving in time and material. A concentration of 0.18 percent for HgCl₂ or New Ceresan was an optimum dosage. Nonsoluble mercury, copper, and zinc compounds did not give a uniform coverage of the seeds. As to pathogens, *Rhizoctonia solani* and species of *Alternaria* and *Fusarium* were tolerant of all the chemicals studied, but ethyl mercury phosphate occasionally decreased the incidence of seeds infected by *Ascochyta blight*. Elimination of *Rhizopus nigricans* permitted *Alternaria* spp. to develop rapidly and also made recognition of the latter easier. Testing the chemically treated peas in towels gave more exact germination data than untreated seeds widely spaced in pasteurized soil.

Disease resistant pea varieties, J. C. WALKER. (Univ. Wis.). (*Canner*, 88 (1939), No. 12, pt. 2, p. 89).—Note on resistance, with special reference to wilt and near-wilt.

Controlling the peanut leaf spot, W. A. JENKINS. (Ga. Expt. Sta.). (*South. Seedsman*, 2 (1939), No. 5, pp. 4, 17, 19, fig. 1).—After summarizing previously noted points relating to the two *Mycosphaerella* leaf spots of peanut (El. S. R., 79, p. 350), the author adds data on reductions in yield and on control. Preliminary trials (1937-38) of sulfur dust (325-mesh) were encouraging, and progress is noted on development of resistant strains of peanuts.

The effects of some agronomic practices on the incidence of *Rhizoctonia*, F. M. BLONDETT. (Cornell Univ.). (*Amer. Potato Jour.*, 16 (1939), No. 4, pp. 93-98).—Although these potato rotation experiments have been in operation for only 3 yr., certain definite results are reported. When potatoes were grown on the same plats for 3 successive years, more *Rhizoctonia* occurred on the tubers than during the longer rotations, but use of 1,000 lb. of a 5-10-5 fertilizer reduced the number of tubers bearing *Rhizoctonia* in the two places where this point was tested. Stable manure also reduced the amount of *Rhizoctonia* on the tubers in all of the places, and a rye cover crop in two of three places. Where potatoes were grown repeatedly on the same plats, the best control was obtained by combining commercial fertilizer, stable manure, and cover crops.

Notes on the photoperiodic reactions and virus contents of some Peruvian potatoes, R. W. G. DENNIS (*Ann. Appl. Biol.*, 26 (1939), No. 1, pp. 87-101, pls. 2).—Exposure of 59 Peruvian potato varieties to full summer day at Cambridge, England, resulted in a more uniform growing period and increased the blooming tendency, but the effect on tuber production varied according to the variety. In most types the weight and number of tubers were not adversely affected, but there was a tendency to elimination of the dormancy period and to conversion of the stolons into aerial shoots. In a few varieties there was no adverse influence, and in one small group the plants exposed to full-day conditions formed no tubers. Study of the virus content indicated only 11 of the 59 varieties to be healthy, in those remaining there being found viruses apparently identical with those known in England as X, B, C, F, G, and perhaps leaf roll. There was also evidence of other viruses, suggesting the existence in America of a virus complex, only isolated members of which have hitherto been known in Europe. Great caution is therefore recommended in introducing South American varieties into potato-growing districts.

Soft rot of pumpkin and watermelon fruits caused by *Pythium ultimum*, C. M. TOMPKINS, P. A. ARK, C. M. TUCKER, and J. T. MIDDLETON. (Calif. and Mo. Expt. Stas.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 6, pp. 461-475, figs. 3).—The soft rot of Zucchini and Mammoth Summer Crookneck pumpkin and watermelon fruits, described as prevalent in California and due to *P. ultimum*, occurs when fruits are in contact with wet soil and is favored by cool weather. The symptoms are described. Invaded fruits may be completely rotted 6-10 days after infection. Certain cucurbit isolates of the fungus, indistinguishable from normal cultures by growth or pathogenic characters, failed to produce oospores, though reproductive bodies resembling oogonia developed in culture. It is suggested that the absence of oospores results from failure to develop antheridia. A minimum of 4° C., an optimum of 25°-28°, and a maximum of 40° were determined for the fungus. All cucurbit isolates and those from roots of alfalfa, tobacco, and spinach, and a culture from an unknown host, had identical temperature relations. Infection of healthy pumpkin and watermelon fruits was obtained by laboratory inoculations, but wounding of watermelon fruits was necessary in order to induce decay. All isolates caused damping-off of pumpkin, watermelon, and tomato seedlings, but older plants were resistant. In the laboratory, green and ripe

tomatoes, eggplant, beans, and field pumpkin proved susceptible to infection without wounding. When wounded, apple, bell pepper, squash, pumpkin (two varieties), watermelon, melons (Casaba, Honey Dew, and Persian), cucumber, turnip, rutabaga, carrot, parsnip, potato, lemon, sweet orange, onion, and sweetpotato all proved susceptible.

Pathology, J. P. MARTIN (*Hawaii. Sugar Planters' Assoc. Proc.*, 58 (1938), *Egypt. Sta. Com. Rpt.*, pp. 30-38).—A review and brief notes on approved projects are presented, including quarantine against foreign plant diseases, especially those of sugarcane; plantation inspection and consultation services; cane diseases in Hawaii, including brown stripe, mechanical injuries, chlorotic streak, lightning injury, *Helminthosporium sacchari* eyespot disease, *Bacterium albilineans* leaf scald, stem galls and their insect relations, mosaic, and growth failure and *Pythium* root rot; physiological disorders of sugarcane, including the relations of nutritional factors and growth-promoting substances; and chromosome studies of sugarcane, with special reference to colchicine effects.

The behavior of POJ 2878 sugar cane in relation to Fiji disease and transmission of the virus by nymphs of *Perkinsiella vastatrix*, G. O. OCFEMIA and M. S. CELINO (*Phytopathology*, 29 (1939), No. 6, pp. 512-517, fig. 1).—The results of this study indicated that among apparently healthy stalks of the P. O. J. 2878 variety selected from a field, two produced shoots some of which were infected with Fiji disease while the others were disease-free. The shoots not showing symptoms of the disease proved to be virus-free. When the apparently healthy shoots arising from the two infected stalks were used in transmission tests they became readily affected with Fiji disease. Besides the adults of *P. vastatrix*, the second, third, fourth, and fifth instar nymphs were shown to be capable of transmitting the Fiji disease virus, but nymphs hatching from eggs of viruliferous leafhoppers did not carry the virus. Viruliferous adults required at least 24 hr. to elapse before they could transmit the disease.

Comparative study of sugarcane mosaic from different countries, J. MATZ. (U. S. D. A.). (*Internat. Soc. Sugar Cane Technol. Cong. [Baton Rouge, La.]*, *Proc.*, 6 (1938), pp. 572-580, figs. 2).—Comparative studies (since 1935) of virus strains from the United States, Puerto Rico, islands of the Pacific, India, and Spain have shown through use of differential hosts the existence of distinct virus types. Sugarcane B. H. 10 (12) has proved to be a most receptive variety to the several available Louisiana and Puerto Rico mosaic virus strains, and with respect to a Hawaiian virus it also served to establish the fact that this virus possesses the property of transmissibility, though in a restricted varietal range. The observations and tests indicate clearly that the mosaic strain from Hawaii used is innocuous to the C. P. 28/60, C. P. 31/294, and Co. 281 cane varieties, which are susceptible to the more prevalent virus strains in North America and Puerto Rico. These studies further indicate that in Tahiti, New Caledonia, and Hawaii there exist mosaic virus strains that are less virulent and more difficult to transmit to varieties that are highly susceptible to the prevalent strains in the United States. The P. O. J. 36 variety was one of the first mosaic-infected canes introduced from Java into Puerto Rico (via Tucuman), and B. H. 10 (12) has been the most widely cultivated variety there in recent years. The virus strains obtained from Puerto Rico on each of these varieties are apparently identical, and are said to be similar to the moderately severe, highly infectious, stable virus 1-B Summers (formerly strain II Louisiana), and to strains from Spain and India. It is deemed fairly conclusive that the four out of five strains from certain Pacific islands have so far proved

to be less infective than the principal types of our common cane mosaic viruses at the present time.

Frenching of tobacco, E. L. SPENCER and G. I. LAVIN (*Phytopathology*, 29 (1939), No. 6, pp. 502, 503).—The authors report spectrographic analyses of greenhouse Turkish tobacco grown in field and composted soils and in sand with and without added TlNO₃ to test the theory that frenching is due to the toxic action of thallium. The data obtained suggested that frenching and known Tl injury are two distinct physiological diseases. However, if the two are due to different agents, it is noted as surprising that the top and root symptoms and the methods of control are so similar. Furthermore, a water extract of nontoxic soil, collected near a natural frenching area, did not produce frenching until supplemented by the additive effect of a nontoxic amount of Tl. It is suggested as not improbable that the toxic action of Tl may be exerted on the root, giving rise to some disturbance affecting the top, and that possibly the Tl compound in the soil may be in a form not so readily translocated into the top as the salt used in the experiments. If this were true the spectrographic detection of Tl only in plants treated with TlNO₃ would not necessarily eliminate thallium as the cause of frenching.

On the molecular weight of the tobacco-mosaic virus protein, V. L. FRAMPTON. (Cornell Univ.). (*Phytopathology*, 29 (1939), No. 6, pp. 495-497).—The author points out the limitations in applicability of the laws of Fick, Pousselle, and Stokes to sols of this virus protein in water or phosphate buffer for the determination of the particle weight, with the conclusion that the laws enunciated by the first two are not followed by these sols but that Stokes' law is valid for the material in question.

Symptoms of yellow ring spot and longevity of the virus in tobacco seed, W. D. VALLEAU. (Ky. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 6, pp. 549-551).—It was found that this tobacco virus could be transmitted through the seed from generation to generation without the formation of ring patterns, i. e., with general leaf-edge chlorosis (yellow strain) symptoms and pollen sterility as the chief signs of the infection. The ring and line patterns are said to be inoculative and invasive symptoms. The survival time found for the virus was 5½ yr.

Root-knot nematode of tomatoes in relation to the Indiana canning crop, G. A. FROST (*Indiana Sta. Bul.* 434 (1939), pp. 15, figs. 8).—As an important pest of canning tomatoes in Indiana, nematodes are said to occur primarily in fields set to plants originating in the South. Infestation was found to produce important effects on the yield of canning fruits, the amount set being reduced and the size being smaller, with the consequent lowering of quality of some types of pack. The decreased income to growers from this pest has amounted to as much as \$32 per acre on the conservative basis of \$12 per ton for U. S. No. 1 and \$7 per ton for No. 2 canning fruits. No evidence has been obtained for the winter survival of *Heterodera marioni* in the open in northern Indiana, though it has been known to live over in Ohio and New York. Rotations are therefore advised to include corn, wheat, oats, sweetclover, grasses, or other resistant hosts, and tomato plants should be examined for infestation before setting out.

Factors affecting development of the bacterial canker of stone fruits, E. E. WILSON (*Hilgardia [California Sta.]*, 12 (1939), No. 4, pp. 257-298, figs. 9).—Criteria were developed to determine rise and fall in activity of the cankers induced by *Phytophthora cerasi*, by which it was seen to begin in late fall, continue through winter and spring, and halt in early summer, bacterial fluctuations in affected tissue accompanying this rise and fall in canker activity.

By successive inoculations (nearly 2 yr. and principally on plum), it was found that the fall period when they were successful corresponded with the period of activity of spontaneous cankers, while the spring period when inoculations failed to take agreed with the time when established cankers ceased activity. Low temperatures in midwinter were correlated with decreased canker extension, whereas rises in temperature in spring were accompanied by increased extension, but failure of inoculations in early fall and early summer was apparently not due to adverse temperatures. Moderately diseased trees on sandy loam were benefited by $(\text{NH}_4)_2\text{SO}_4$ fertilization, seemingly from an enhanced ability to repair damage by the disease. The results of controlled soil moisture tests are interpreted as indicating that a lack of available moisture affects the disease adversely, whereas wide differences short of actual lack of available moisture did not appear to influence the disease. The severity of the disease locally is conditioned by the varieties grown. Distinction is made between susceptibility to infection and susceptibility to inroads by the cankers once infection becomes established, and examples are given. Internal host reactions to the presence of diseased areas are considered as to those induced (1) by the vascular cambium and (2) by the phellogen, and major aspects of development of the phellogen and resultant periderm around diseased areas at canker margins are described. These phenomena are shown to depend on the growth activity of the tree. Varieties that begin growth early developed periderm around diseased areas and callus at wound surfaces earlier than others that begin growth late. Observations on plums appear to indicate that cankers in early-blooming varieties stop activity earlier in spring than those in late-blooming varieties. Experimental data showed a certain relation between phellogen occurrence and cessation of canker extension, but failed to prove that the periderm actually prevented canker activity. Twenty-two references are given.

Host organs attacked by bacterial canker of stone fruits, E. E. WILSON and W. B. HEWITT (*Hilgardia [California Sta.]*, 12 (1939), No. 4, pp. 249-255, figs. 3).—The less common symptoms on leaves, blossoms, fruit, fruit stems, green shoots, and buds of *Prunus* spp. are discussed in their relation to severe outbreaks. Bacteria isolated from leaves, blossom buds, fruit stems, fruit and green terminal shoots of cherry, apricot, and plum induced cankers identical with those due to *Phytophthora cerasi* from plum. Leaf, fruit, fruit stem, and green shoot infections have not contributed to the severity of epidemics. These infections commonly arise from bacteria originating in bud infections and twig lesions. Blossom and particularly bud infections are frequently serious and develop concurrently with outbreaks of limb cankers. Such infections cause direct crop losses, reduce future fruitfulness of branches, and produce foci for invasion of large limbs. The symptoms resemble those of bacteriosis of cherries and plums in England. In other studies the causal bacteria of the two diseases have proved identical.

Peach mosaic, G. L. STOUT (*Calif. Dept. Agr. Bul.*, 28 (1939), No. 3, pp. 177-200, figs. 10).—The author reviews the discovery and early history of the disease, including early studies by Reed and Thornberry in California (E. S. R., 74, p. 349), where by 1933 it is said to have come into general prominence and to have aroused much concern. Discussions follow, summarizing present data on the virus nature of the malady, descriptions of the blossom, foliage, fruit, and twig symptoms, the effects on fruit production, its transmission and spread (including extensive orchard records under the author's supervision), hosts, control methods, and a survey of current control operations in California. Fifteen references are included.

Observations on powdery mildew on cultivated blueberries in Massachusetts in 1938, H. F. BERGMAN. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 6, pp. 545, 546).—Of the varieties now grown in Massachusetts, Pioneer is said to be the most susceptible to the *Microsphaera* powdery mildew, with Cabot and Wareham following in the order named, and Harding and Katherine apparently the most resistant. Data are presented suggesting the possibility of obtaining by selection from crosses varieties that will be more resistant than those now grown.

Avocado sun-blotch in Florida, H. E. STEVENS. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 6, pp. 537-541, fig. 1).—Definite cases of sun-blotch, a disease believed to be of virus origin, are reported from a single grove in Florida, but only on Taylor and Nabal avocados topworked on Taft trees. The possible source of this infection is discussed, but is believed to be obscure unless the Taft variety served as a latent carrier. Sun-blotch has occurred previously in Florida only in sporadic cases.

Scaly bark in relation to propagation of citrus trees, H. S. FAWCETT. (Calif. Citrus Expt. Sta.). (*Calif. Citrog.*, 24 (1939), No. 7, pp. 242, 262, figs. 3).—This is a summary of the author's studies of this transmissible disease, now believed to be of virus origin, discovery of the leaf symptoms of which (1933) is said to have furnished a means of studying the malady and of indicating something of its real nature. See also a previous note (E. S. R., 80, p. 505).

Economics of scaly bark in orchard management, H. HEPNER (*Calif. Citrog.*, 24 (1939), No. 7, pp. 242, 250, 251).—This is a general discussion of the effects of psorosis on citrus orchard efficiency, with detailed analysis of returns in a ± 8 -acre orchard where ± 12 percent of badly diseased trees are estimated to have decreased the profits by 28 percent.

Recommendations for the control of scab and foliage diseases of pecans in the Southeast, J. R. COLE and J. R. LARGE (U. S. Dept. Agr., Bur. Plant Indus., 1938, pp. 4).—Directions are given for controlling these diseases by sanitation and by spraying with bordeaux mixture.

A bud and twig blight of azaleas caused by *Sporocybe azaleae*, W. H. DAVIS. (Mass. State Col.). (*Phytopathology*, 29 (1939), No. 6, pp. 517-529, figs. 2).—This blight is reported as threatening to exterminate some species of the cultivated and native azaleas in Massachusetts. The fungus, related to *Graphium ulmi* and in like manner plugging the vessels with tyloses, has been reported as parasitizing rhododendrons in New Jersey and California, but only two infected buds were observed on these hosts in Massachusetts. The symptoms on infected buds, flowers, and plants and the cultural characters of the fungus are described. For the substratum \pm pH 6 was preferable, and the optimum temperature for growth was 22°-25° C. A maturing culture is described. Initial infection was found to occur in the axils of the lower bud scales, where bud and stem tissues were penetrated, the fungus then advancing into the bark and pith cells filled with stored starch grains and traversing the vascular system. The parasite kills the buds, prevents the formation of new flowers, leaves, and stems, arrests photosynthesis, girdles the stems, and plugs the phloem, all of which results in necrosis. The fungus could be cultured from infected stems as long as the inner bark remained green. Nine azalea and rhododendron (the same generic name used for both) species were inoculated, the results indicating *Rhododendron arborescens* and *R. viscosum* to be resistant, and *R. nudiflorum* and *R. canescens* to be susceptible. The rhododendrons are considered resistant. The disease was controlled by pruning and destroying infected materials, and either spraying or dusting with copper fungicides (copper-lime dust 57 or 5-5-50 bordeaux used).

Fungi of the Duke Forest and their relation to forest pathology, F. A. WOLF, with collab. of K. H. GARREN and J. K. MILLER (*Duke Univ. Forestry Bul.* 2 (1938), pp. 122, figs. 53).—The stated purpose of the present bulletin was to record the fungi collected in the Duke Forest during the past 6 yr. The list is not limited to species on woody plants because herbaceous species are ecologically a part of the forest and some of them are alternate hosts for certain of the rusts. Consideration is given to the more important pathological problems suggested by the collections and observations, and to an evaluation of the status of available knowledge of certain specific tree diseases. The more important fungi causing diseases or decays are discussed for alder, ash, beech, buckeye, cedar, cherry, elm, sweet gum, hickory, holly, honey locust, black locust, maple, mulberry, oak, pine, tulip poplar, red bud, dwarf sumac, sycamore, and black willow, and for the fir-fern rusts. A list of fungi systematically arranged and a host index are included.

A survey of forest tree diseases and their relation to stand improvement in the Lake and Central States, R. C. LORENZ and C. M. CHRISTENSEN. (Coop. Univ. Minn. et al.). (*U. S. Dept. Agr., Bur. Plant Indus.*, 1937, pp. [5]+52, pls. 11, fig. 1).—The report (with 28 literature references) of this survey discusses the nature and causes of tree diseases, tabulates the estimated prevalence of diseases of conifers and of hardwoods in the Lake and Central States, considers specific diseases (heart rots, cankers, burls, needle and twig diseases of conifers, leaf diseases of hardwoods, mycorrhizas, mistletoe, and nonparasitic diseases), gives an example of a disease problem on a timber sale area (aspen) involving *Fomes ignarius*, and discusses forest practices and their effects on diseases.

Observations on fructification of *Ceratostomella ulmi* in England, J. M. WALTER. (*U. S. D. A.*). (*Phytopathology*, 29 (1939), No. 6, pp. 551-553).—In England, very abundant coremia and perithecia of *C. ulmi* were noted in dead, dying, and fallen elms. Their most plentiful development was on the xylem surface of trees from which the bark had just begun to loosen, but they develop commonly in the galleries of the bark beetles *Scolytus scolytus multistriatus*. The largest numbers of perithecia were found on surfaces that had produced coremial stands 2-4 weeks previously. Logs in contact with moist soil yielded more extensive stands of coremia and perithecia than standing dead trees. Fresh coremia were found throughout the year, but during the observation period (3 yr.) perithecial development apparently ceased during November and did not begin again until about mid-March.

Scouting and sampling elms with symptoms commonly associated with the Dutch elm disease as an aid in eradicating *Ceratostomella ulmi*, R. P. TRUE and S. S. SLOWATA. (*U. S. D. A. et al.*). (*Phytopathology*, 29 (1939), No. 6, pp. 529-537, fig. 1).—Biweekly observations on 2,289 trees in 1936 and 4,424 trees in 1937 indicated that as the summer advanced the number of elms showing these external symptoms increased markedly until mid-September, when defoliation set in. However, only a small percentage of the trees observed proved to be actually infected with *C. ulmi*, and those showing symptoms plus *C. ulmi* infection before September 1 nearly all did so before mid-August. The efficiency of symptom sampling was at its maximum during late June and throughout July. In the most completely sampled plats 12-26 percent of the trees showed external symptoms, while 3-10 percent of the latter also showed internal symptoms and had to be diagnosed by culturing from selected samples. By this technic, 0.007-2.325 percent of all the trees were found infected. Among 419 felled plat trees, careful examination and culturing indicated 12 trees not showing external symptoms to be infected with *C. ulmi*. Nine of 24 infected trees recovered in the sense that the infection became occluded, though the fungus was found to have

remained alive within certain trees for several years. The ultimate relation of such infections to eradication is at present unknown.

The relation of *Saperda tridentata* to infection of American elm by *Ceratostomella ulmi*, L. J. TYLER, K. G. PARKER, and L. L. PECHUMAN. (Cornell Univ.). (*Phytopathology*, 29 (1939), No. 6, pp. 547-549).—Through wounds made by the common elm borer, *S. tridentata*, 2- to 4-yr. budded elms in pails were inoculated in the greenhouse with *C. ulmi*, infection being obtained whether inoculation was by fungus-infested beetles or by atomizing these wounds with a spore suspension. However, the infected trees failed to wilt, and examination indicated that the fungus invasion was not extensive, due, it is believed, to the fact that the beetles fed on the more succulent parts of growing shoots. Injection of spores into such tissue on other trees also failed to result in extensive invasion. Inoculation by infested beetles was slightly more successful than by atomizing the wounds with spore suspensions.

The hemlock rust caused by *Melampsora farlowii*, G. H. HEPTING and E. R. TOOLE. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 6, pp. 463-473, figs. 2).—In certain commercial nurseries of western North Carolina, eastern hemlocks had up to 82 percent of their 1938 shoots killed by a twig blight shown by inoculations to be due to the autoecious *M. farlowii*. Carolina hemlock proved much more resistant. In spraying experiments the most efficient control was obtained by weekly spraying with lime-sulfur (4 lb. dry form to 50 gal. water) through May. Sprayed trees had 3 percent of their twigs killed, as compared with 19 percent for the controls. The cost of spraying a 2- to 5-ft. tree was 4 mills per tree per application.

New species of *Taphrina* on red maple and on silver maple, A. E. JENKINS. (U. S. D. A.). (*Jour. Wash. Acad. Sci.*, 29 (1939), No. 5, pp. 222-230, figs. 4).—*T. dearnessii* n. sp., causing a leaf blister of *Acer rubrum*, and *T. carverii* n. sp., one of *A. saccharinum*, are described and illustrated.

Growth and variability of *Stereum gausapatum* in culture, J. A. HERRICK (*Phytopathology*, 29 (1939), No. 6, pp. 504-511, figs. 3).—The causal fungus of heart rot of oak was studied by culturing on agar, the 58 isolates used representing collections at various points throughout the northeastern United States. Transfers from old agar cultures or from those recently derived therefrom grew in an unpredictable way. However, a sufficient number of successive transfers, made at short intervals, gave rise to cultures of predictable behavior, the number of successive transfers necessary for such results varying widely among the 58 isolates. Intensive studies of 12 selected isolates grown in Petri dishes at 25° C. showed them to vary widely in growth rate, as well as in mycelial character and color, but the various individual isolates remained constant in cultural characteristics throughout the nearly 2 years' duration of the study.

Ceratostomella ips associated with *Ips lecontei* in Arizona, D. E. ELLIS (U. S. D. A. et al.). (*Phytopathology*, 29 (1939), No. 6, pp. 556, 557).—The blue-staining fungus *C. ips* is reported in association with the bark beetle *I. lecontei* attacking *Pinus ponderosa* in Arizona.

ECONOMIC ZOOLOGY—ENTOMOLOGY

The wildlife restoration program under the Pittman-Robertson Act of 1937, A. M. DAY (U. S. Dept. Agr., Misc. Pub. 350 (1939), pp. 12).—This discusses the purpose of the wildlife restoration program, types of suitable projects, projects not contemplated by the act, methods of allocating funds to the States, and project initiation and accomplishment procedure, and gives the text of the Federal law and regulations.

Wildlife of the Atlantic coast salt marshes, W. L. McATEE (*U. S. Dept. Agr. Cir. 520* (1939), pp. 28, pls. 6, figs. 10).—This circular refers briefly to the zones of salt-marsh plants and the plants of these zones and their value to wildlife, then takes up the more characteristic species of birds, the less characteristic species of fowl, and notes on other wildlife, including reptiles, fishes, and mammals.

Shortening daylight periods between May 15 and September 12 and the pelt cycle of the mink, T. H. BISSENETTE and E. WILSON (*Science*, 89 (1939), No. 2314, pp. 418, 419).—The author presents evidence to show that the assumption of winter prime pelt by mink may be induced in summer despite relatively high temperatures or hastened in autumn by reducing the duration of the periods of light (and/or its intensity) to which the animals are exposed daily.

The muskrat [trans. title], H. N. KLUYVER (*Tijdschr. Plantenziekten*, 42 (1936), No. 12, pp. 311-340, pls. 4, figs. 5; also *Verslag. en Meded. Plantenziektenkund. Dienst Wageningen*, No. 85 (1937), pp. 33, pls. 4, figs. 5).—A discussion of the biology and economic importance of the muskrat (*Ondatra zibethica*) in western Europe, where it has become established at many points.

Some notes on rat control in the Mourilyan area, E. H. FOX (*Queensland Soc. Sugar Cane Technol. Proc.*, 8 (1937), pp. 37-39).—The observations reported are said to indicate that over 50 percent of the field rats in the Mourilyan area of Queensland belong to the species *Melomys littoralis*.

Combating the field rat in ricefields, P. VAN DER GOOT (*Landbouw [Buitenzorg]*, 13 (1937), No. 9, pp. 405-421; *Eng. abs.*, pp. 419-421).—A comprehensive account of the common field rat (*Mus rattus brevicaudatus*) in the rice fields of Java and means for combating it.

Parasites of some Minnesota Cricetidae and Zapodidae, and a host catalogue of helminth parasites of native American mice, A. B. ERICKSON (*Amer. Midland Nat.*, 20 (1938), No. 3, pp. 575-589, figs. 18).—This contribution, which includes descriptions of five new species and the erection of the jumping mouse genus *Spiruracerca*, is presented with a host catalog of helminth parasites of native North American mice.

The chemistry and toxicology of pest control [trans. title], G. PETERS (*Samml. Chem. u. Chem. Tech. Vorträge. n. ser.*, No. 31 (1936), pp. 120, figs. 22).—This contribution, presented in 10 chapters, is accompanied by 201 references to the literature.

Insects and other animal pests (*Nebraska Sta. Cir. 60* (1939), pp. 47-51, fig. 1).—A brief summary of some of the more important work conducted by the station since its organization.

[Report of work with economic insects in western Washington] (*Western Washington Sta. Rpt. 1938*, pp. 20-24).—Reference is made to work with the cabbage weevil *Ceutorhynchus assimilis* Payk. and the carrot rust fly, both by A. J. Hanson and R. L. Webster; the life history and control of the cherry fruitworm in western Washington, by E. P. Breakey and Webster; and holly insects and their control, the effect of the solvent on rotenone in solution, and the resistance of plants to insect attack, all by Breakey.

Report on the natural enemies in Haiti of the horn-fly (*Lyperosia irritans*) and the green tomato bug (*Nezara viridula*), J. G. MYERS (*Jour. Council Sci. and Indus. Res. [Australia]*, 11 (1938), No. 1, pp. 35-46, fig. 1).—In the course of an intensive study of the parasites of the horn fly and the southern green stinkbug in Haiti the author found considerable evidence that the former is largely controlled there by natural enemies, of which the most important are a histerid beetle and an anthomyiid larva, both predaceous on the horn fly maggot. The southern green stinkbug is parasitized in Haiti in October and November by a tachinid fly (*Trichopoda* sp.) to the extent of only 4.1 percent.

It is suggested that *T. pennipes* F. in Florida is a more efficient and promising parasite.

Department of entomology, S. G. JARY and M. D. AUSTIN (*Jour. Southeast. Agr. Col., Wye, Kent, No. 41 (1938), pp. 9-14*).—Notes on the occurrence of the more important insects and a brief reference to the experimental work conducted are given with a list of 11 references (*E. S. R.*, 77, p. 219).

[Contributions on economic insects in the Soviet subtropics] (*Soviet Subtrop. (Soviet Subtrop.)*, No. 12 (28) (1936), pp. 26-70, figs. 27; *Eng. abs.*, pp. 33, 40, 58, 65, 70).—Included among the contributions presented are the following: The Scale Species [Principally *Pulvinaria floccifera* Targ. and *Aspidiotus destructor* Sign.] in the Tea Regions, by Sh. I. Patarafa (S. I. Pataraya) (pp. 26-33); The Problem of Citrus Tree Fumigation With Hydrocyanide Gas, by M. P. Voitenko (pp. 34-40); Mechanisation of Citrus Pest Control, by Ů K. Kirtbafa (J. K. Kirtbaya) (pp. 41-58); The Pests of the Main Essential Oil Plants in the Crimea, by S. M. Fedorov and E. P. Kozlova (pp. 59-65); and The Pests [Principally the European Red Mite and the Soft Scale] and Diseases of Citrus Plants Grown in Pots, by I. Seletskiĭ (J. Seletzki) (pp. 66-70).

Report of the entomological section, H. WILKINSON (*Kenya Dept. Agr. Ann. Rpts.*, 1935, vol. 2, pp. 60-70; 1936, vol. 2, pp. 43-54).—The occurrence of and work with economic insects in Kenya are reported for the years 1935 and 1936.

Division of entomology, annual report for year 1936, R. W. JACK (*Rhodesia Agr. Jour.*, 34 (1937), No. 7, pp. 570-592).—The occurrence and the work of the year with economic insects, including those of medical and veterinary importance, are reported upon (*E. S. R.*, 76, p. 657).

[Report of entomological work in the Sudan during the season 1934-35], H. W. BEDFORD (*Sudan Govt., Agr. Res. Serv. Ann. Rpt.*, 1935, pp. 63-96, pls. 2).—The work reported upon relates to a general survey of insect pests of crops in the Sudan (including enemies of cotton and sorghum and two garden pests), experimental work with and control measures for the same pests, forest entomology, veterinary entomology, and apiculture.

Report of the entomologist, 1935, A. H. RITCHIE (*Tanganyika Dept. Agr. Ann. Rpt.*, 1935, pp. 95-103).—A report of the occurrence of and work of the year with insects in Tanganyika (*E. S. R.*, 74, p. 229), particularly those attacking coffee, and notes on cotton and miscellaneous pests.

[Report of work in entomology in 1935-36 and 1936-37] (*Uganda Dept. Agr. Ann. Rpts.*, 1936, pt. 2, pp. 8-39; 1937, pt. 2, pp. 7-42).—In the report for 1935-36, reports by H. Hargreaves (pp. 8-11) and A. M. Gwynn (pp. 12-18) deal with the occurrence of and work with the more important insects of 1935 (*E. S. R.*, 75, p. 808), followed by an extended report on a year's investigation of the pink bollworm in Uganda, March 1935 to April 1936, by T. H. C. Taylor (pp. 19-39). For 1936-37 the work reported upon includes the Report of the Senior Entomologist for 1936, by H. Hargreaves (pp. 7, 8), the Report of the Entomologist, Serere, 1936-37, by A. M. Gwynn (pp. 33-39), and Pink Boll Worm (*Platyedra gossypiella* Saund.), by T. H. C. Taylor (pp. 40-42). In a Report on Investigations of Cotton Stainers (*Dysdercus* spp.) for 1936, H. Hargreaves and T. H. C. Taylor (pp. 9-32) report upon the bionomics, alternative host plants, natural control, annual cycle, and measures for control of the four species of *Dysdercus* occurring on cotton in Uganda (*D. nigrofasciatus* Stal, *D. superstiosus* Sign., *D. fasciatus* Sign., and *D. cardinalis* Gerst.).

Entomological investigations, G. A. JULIUS ET AL. (*Austral. Council Sci. and Indus. Res. Ann. Rpt.*, 11 (1937), pp. 15-21).—The progress of investigational work (*E. S. R.*, 77, p. 815) with ectoparasites and with blood parasites of cattle; ephemeral fever of cattle (suspected of being insect-borne); orchard and fruit

pests, including the oriental fruit moth and the codling moth; field and pasture pests; termites; several other insect and snail pests, etc., is briefly considered.

Insect pests of the maize-crop in Java, C. J. H. FRANSSEN (*Landbouw [Buitenzorg]*, 12 (1936), No. 2, pp. 57-105, figs. 72; *Eng. abs.*, pp. 104, 105).—Brief notes are given on the life history and control of 41 species of insects attacking corn in Java, most of which are of minor importance. The 11 which occasionally cause serious damage are the white grubs *Holotrichia helleri* Brske. and *Aprosterna aerea* Perty, the larvae of the weevil *Hypomeces squamosus* F., 3 cutworms (the black cutworm, *Euxoa segetum* Schiff., and *E. interjectionis* Guen.), the European corn borer, the purplish stem borer *Sesamia inferens* Walk., the grasshopper *Valanga nigricornis* Burm., the armyworm *Laphygma exempta* Walk., and the cantharid beetle *Epicauta ruficeps* Ill., and these are treated somewhat more in detail.

Cotton insect investigations. (Coop. U. S. D. A.). (*Georgia Coastal Plain Sta. Bul.* 29 (1938), pp. 78, 79, figs. 2).—Brief report is made of the results of control work with the bollweevil on upland, or short staple, and sea-island, or long staple, cotton.

Some insects injurious to pear-trees, S. TSENG and C. Ho (*Lingnan Sci. Jour.*, 16 (1937), Nos. 2, pp. 249-259; 3, pp. 457-462, pls. 3).—Descriptions of the several stages, life history and habits, distribution and habitat, and control measures are reported for the tree cricket *Calypotrypus tibbinonis* Mats. and the pear stinkbug *Urochela luteovariorum* Distant, common and injurious enemies of orchards in Tsingtao, and for *Rhynchites heros* Roel., which is widely distributed, causing great damage to the fruit.

Insect and allied pests of the papaw, J. H. SMITH (*Queensland Agr. Jour.*, 48 (1937), No. 5, pp. 553-557, figs. 7).—In this brief account particular mention is made of the common red spider, the fruit-spotting bug *Amblypelta lutescens* Dist., the southern green stinkbug, and the yellow peach moth *Dichocrocis punctiferalis* Guen. as enemies of the papaw.

[**Observations on citrus insects near Swatow, China**], I. J. CONNIT, W. EL. HOFFMANN, and H. C. WANG (*Lingnan Agr. Jour.*, 1 (1935), No. 2, pp. 192-235, figs. 24; *Eng. abs.*, pp. 242-245).—Observations of some 80 insect pests of citrus in China, most of which are known to occur in Kwangtung Province, are reported. The majority of these are briefly described and biological and bionomical notes given.

[**Notes on citrus insects in Kwangtung Province, China**], W. EL. HOFFMANN (*Lingnan Agr. Jour.*, 2 (1936), Nos. 1, pp. 165-218, figs. 42, *Eng. abs.* pp. 215-218; 2-4, pp. 378-396, figs. 3, *Eng. trans.* pp. 384-396).—These contributions, in the first of which 38 miscellaneous insects of importance and in the second papilionid and lycaenid caterpillars are considered, supplement the account above noted.

[**Coconut and coffee pests in New Guinea**], J. L. FROGGATT (*New Guinea Agr. Gaz.*, 2 (1936), No. 3, pp. 18-24).—Brief accounts are given of the more important insect enemies of the coconut (pp. 18-21) and of two coccid pests (*Pseudococcus* sp. and the green scale) of coffee (pp. 22-24).

Pests of the carnation and their control, EL. R. SPEYER (*Sci. Hort. [Wye, Kent, Eng.]*, 6 (1938), pp. 72-85, pls. 2).—This contribution from the Experimental and Research Station, Cheshunt, Herts, includes a list of 43 references to the literature.

Pests of commercial ornamental plants, G. FOX WILSON (*Sci. Hort. [Wye, Kent, Eng.]*, 6 (1938), pp. 102-116).—Included in this account is an appendix listing the chief pests of some ornamental flowering and foliaged plants grown for market, including their host plants and common names.

Recent research on wood-destroying insects, R. C. FISHER (*Jour. Roy. Soc. Arts*, 85 (1937), No. 4400, pp. 407-425, figs. 2).—A review of recent work with *Lyctus* powder-post beetles and the deathwatch beetle *Xestobium rufovillosum* DeG.

Destruction of timber by marine organisms in the port of Brisbane, C. J. J. WATSON, F. A. McNEILL, R. A. JOHNSON, and T. IREDALE (*Queensland Forest Serv. Bul.* 12 (1936), pp. X+107, figs. 23).—The results of over 5 yr. of intensive research on the destruction of timber by marine organisms, conducted by the Queensland Forest Service, are reported. Nine distinct species of destructive timber borers have been discovered in the Brisbane River and Moreton Bay, and the damage occasioned by each on a range of special test samples was systematically observed at several carefully selected control stations. These methods enabled the relative resistance of each timber to be determined.

In a systematic account of the terebrid mollusks of South Queensland, by T. Iredale (pp. 31-44), the genus *Glumebia* is erected and seven species representing six genera are described as new to science.

Studies on some of the factors involved in the use of sodium arsenite against the Mormon cricket (*Anabrus simplex* Hald.), E. B. HASTINGS and J. H. PEPPER (*Montana Sta. Bul.* 370 (1939), pp. 26, figs. 8).—Earlier studies have shown the desirability of using some diluent in spreading the sodium arsenite used in the field to combat the Mormon cricket in order to better regulate the distribution of the poison. In the experiments here reported hydrated lime, bentonite, calcium carbonate, celite, diatomaceous earth, and volcanic ash, when added to sodium arsenite, were found to act solely in the role of diluents. The uniformity of the dust cloud was shown to depend largely on the difference in size of the particles of the diluent. The diluents tested were not effective in insuring a uniform distribution of the sodium arsenite. Thus, the dust cloud was not a measure of the distribution of the poison.

"Prolonged jarring of receptacles containing mixed dusts did not alter appreciably the concentration either on the top or bottom of the containers. Sodium arsenite dusts were found to be effective in treating Mormon crickets when applied either as purely contact poisons or as stomach and contact poison combined. When their tarsi alone were dipped in the dust the length of time to obtain a 50-percent mortality of the crickets was greatly increased. An increase in temperature was found to bring about a corresponding decrease in time for a 50-percent kill in both nymphs and adults when dusted with sodium arsenite dusts. Temperature changes were found to have a greater effect on adults than on immature stages. Each of the six diluents studied was apparently inert when used in connection with cricket dusts. If sodium arsenite dust is removed from the surface of crickets within 45 min. after dusting, a considerable decrease in percentage mortality may be expected."

The desert locust, R. C. MAXWELL DARLING (*Sudan Notes and Rec.*, 19 (1936), No. 1, pp. 163-175).—This is an account of *Schistocerca gregaria* Forsk., investigations of which and of the red locust *Nomadacris septemfasciata* Serv. and the tropical migratory or hairy chested locust *Locusta migratoria migratorioides* R. & F., the forms of major economic importance in Africa, are under way.

Banana rust thrips control, N. E. H. CALDWELL (*Queensland Agr. Jour.*, 48 (1937), No. 4, pp. 392-399, fig. 1).—An account of *Scirtothrips signipennis* Bagn., long known as a pest of cultivated bananas in Queensland and of increasing importance in the last two decades.

The control of banana rust thrips, N. E. H. CALDWELL (*Queensland Agr. Jour.*, 50 (1938), Nos. 2, pp. 144-163, figs. 3; 3, pp. 295-316, figs. 3; 4, pp. 422-449, figs. 4; 5, pp. 576-584).—A report of further studies of the biology, im-

portance, and control of *Scirtothrips signipennis* Bagn., as related to the rust of banana fruit in Queensland.

A leaf-hopper (jassid) on rhododendron, G. Fox Wilson (*Jour. Roy. Hort. Soc.*, 62 (1937), No. 5, pp. 210-213, pls. 4).—A North American jassid enemy of rhododendrons (*Graphocephala coccinea* Forst.) that has been introduced into Great Britain and become well established in Surrey gardens is reported upon.

Progress of work on *Sexava* spp., the coco-nut treehopper, B. A. O'CONNOR (*New Guinea Agr. Gaz.*, 3 (1937), No. 1, pp. 1-4).—This contribution on coconut treehoppers (*Sexava* spp.) supplements the report by Froggatt previously noted (*E. S. R.*, 76, p. 218).

Aphis migration and distribution in relation to seed potato production, W. M. DAVIES (*Sci. Hort. [Wye, Kent, Eng.]*, 5 (1937), pp. 47-54).—The importance of a knowledge of the influence of local conditions upon the movement of aphids in the raising and maintenance of virus-free stocks of crop plants is emphasized.

Kwangtung Aphididae including hostplants and distribution, W. E. HOFFMANN (*Lingnan Sci. Jour.*, 16 (1937), No. 2, pp. 267-302; *Chin. abs.*, p. 302).—The present contribution records 25 additional species of aphids from Kwangtung, making 64 species from the Province and representing about one-half of the species that have been recorded from the whole of China. The notes on these species include synonymy, Kwangtung hosts, and hosts elsewhere. A plant host list and an index to Kwangtung aphids are included.

The cabbage aphid (*Brevicoryne brassicae* L.), F. R. PETHERIDGE (*Jour. Min. Agr. [Gt. Brit.]*, 45 (1938), No. 2, pp. 140-148, pls. 2).—Observations on the life history and experiments on control of the cabbage aphid, one of the most serious pests of cabbage and related plants in Great Britain, are reported.

A list of the scale insects and mealy bugs (Coccidae) and their host-plants in South Africa, H. K. MUNRO and F. A. FOUCHÉ (*Union So. Africa Dept. Agr. and Forestry Bul.* 158 (1936), pp. 104).—A list of host plants (pp. 11-68), a list of insects (pp. 69-96), and the known distribution of species of Coccidae notified as pests (pp. 97, 98), together with a vocabulary of English common names are presented.

The cyanide fumigation of citrus trees in the eastern Cape Province, South Africa, B. SMIT (*Union So. Africa Dept. Agr. and Forestry Bul.* 171 (1937), pp. 39, pl. 1, figs. 22).—This is a practical account of cyanide fumigation of citrus trees for scale control in the Union of South Africa.

Researches on the development and epidemiology of *Aspidiotus pyri* (Licht.) Reh. on the generation of the year 1935, G. I. SZÉLÉNYI (*Kísérlet. Közlem.*, 39 (1936), No. 4-6, pp. 159-170, fig. 1; *Ger., Eng. abs.*, pp. 168-170).—This contribution deals with a scale insect which is widely distributed over Hungary and infests a variety of hosts, principally apple and pear.

Sexual dimorphism and post-embryonic growth in *Dialeurodes dissimilis* Quaint. and Baker (Homoptera, Aleurodidae), M. L. ROONWAL (*Natl. Acad. Sci., India, Proc.*, 6 (1936), No. 3, pp. 196-203, figs. 3).—Having shown for the first time that sexual dimorphism occurs in the nymphs of a species of the Aleurodidae (*D. dissimilis*), the author is led to believe that it occurs in other Aleurodidae as well.

Studies on gustatory reactions and feeding of wattle bagworm, with special reference to dusted foliage, L. B. RIPLEY, B. K. PETTY, and P. W. VAN HEERDEN (*Union So. Africa Dept. Agr. and Forestry, Sci. Bul.* 148 (1936), pp. 27, figs. 12).—The details of the work conducted are graphically presented in charts.

Control of the wattle bagworm *Acanthopsyche junodi* Heylaeris by dusting with natural cryolite. L. B. RIPLEY, B. K. PETTY, G. A. HEBURN, and J. P. V. D. WESTHUYSEN (*Union So. Africa Dept. Agr. and Forestry, Sci. Bul.* 152 (1936), pp. 22).—In continuation of the preliminary contributions (E. S. R., 74, p. 520), the report here presented includes the results of some fifty field tests over two seasons during which more than 10 tons of natural cryolite were applied. They are said to have removed all doubt as to the efficiency and practicability of its use.

On the development of the tusser *Antheraea pernyi* Guérin-Meneville, with special reference to the comparative embryology of insects. S. SATTO (*Jour. Faculty Agr., Hokkaido Imp. Univ.*, 40 (1937), No. 2, pp. 35–109, pls. 11, figs. 4).—This contribution on the silk-producing tussah moth *A. pernyi* is presented with a list of 160 references to the literature.

Controlling the fruit-tree leaf roller. L. HASEMAN and H. E. BROWN (*Missouri Sta. Cir.* 203 (1939), pp. 4, figs. 2).—A practical account.

Notes on the biology of the nun moth and its main insect parasites [trans. title], S. KOLUBAJTIV (*Lesnická Práce*, 16 (1937), No. 4, pp. 169–199, figs. 2; *Ger., Eng. abs.*, pp. 196–199).—An account is given of the biology of *Porthetria* (*Lynantria*) *monacha* L. and its parasites, of which the tachinid *Parasetigena silvestris* B. B. (= *segregata* Rond.) is the most important.

The apple pith moth. M. MILES (*Jour. Min. Agr. [Gt. Brit.]*, 44 (1937), No. 2, pp. 138–142, pls. 3).—This is an account of *Chrysoclista atra* Haw., which has caused a great deal of damage locally in apple plantations in the south and east of England, and in the spring of 1936 became more serious and widely distributed in south Lincolnshire, Cambridgeshire, Kent, and Hertfordshire.

Contribution to the knowledge of the morphology and biology of *Polia* (*Mamestra*) *pisi* L. [trans. title], A. MELIS (*Redia*, 22 (1936), pp. 1–31, pls. 4, figs. 20; pp. 33, 34; *abs. in Rev. Appl. Ent.*, 24 (1936), Ser. A, No. 8, pp. 484, 485).—Observations of the life history and bionomics of a noctuid, the larvae of the first generation of which in Italy skeletonize the leaves of peas and cause a marked reduction in the crop. It was determined later to have been *Barathra* (*Mamestra*) *brassicae* L.

Notes on the life history of *Prodenia littoralis* Boisdu. (Lep., Noctuidae), Y. C. NG (*Lingnan Sci. Jour.*, 16 (1937), No. 2, pp. 261–266, pl. 1; *Chin. abs.*, p. 266).—This is a report of observations of *P. littoralis*, a very general feeder known as the tobacco cutworm, in Canton, where during the latter half of the year three generations were recorded and in which during October, November, and December it requires some 40 to 45 days to complete its life cycle.

Studies on the spring brood larvae of the paddy borer *Schoenobius incertellus* Walker. C. Y. LIU (*Lingnan Sci. Jour.*, 15 (1936), No. 4, pp. 548–556; *Chin. abs.*, p. 556).—In observations at Kashing and Hangchow, China, from 86 to 98 percent of the hatched larvae of the rice borer *S. incertellus* were found to be able to bore into the seedlings. The percentage of survival of the spring brood larvae in terms of mature larvae and pupae varied from 0 to 10. The submergence of leaf sheath of the rice seedling is suggested as a possible method to prevent the larvae from boring into the seedlings after hatching and to kill those which have previously bored into the seedlings, but there are still some problems to be cleared up.

The light-brown apple moth *Tortrix postvittana* Walker. J. W. EVANS (*Tasmanian Jour. Agr.*, 8 (1937), No. 3, Sup., pp. [2] + 18, figs. 6).—An account of the life history, bionomics, and economic importance of and control measures for *T. postvittana*. This is the most injurious insect enemy of apples in certain districts in Tasmania, where under orchard conditions there are two generations each year, only one of which damages fruit.

Contribution to a study of the anatomy and physiology of the larval stage of the Mediterranean flour moth (*Ephestia kuehniella* Zell.) [trans. title], R. G. BUSNEL (*Rev. Path. Vég. et Ent. Agr. France*, 24 (1937), No. 2, pp. 137-162, figs. 5).—This contribution is presented with a list of 15 references.

A contribution to the study of *Ephestia elutella* Hbn. [trans. title], F. CHABOUSSOU (*Rev. Zool. Agr. et Appl.*, 36 (1937), Nos. 2, pp. 20-32, figs. 3; 3, pp. 36-48, figs. 4; 6, pp. 81-90, fig. 1; 7, pp. 100-109; 10, pp. 154-158; 12, pp. 184-190).—This contribution deals with the anatomy, physiology, life cycle, parasites, economic importance, and means of control of the adult and larval stages of the tobacco moth. The contribution is accompanied by a bibliography of 37 titles.

Studies on the apple fruit borer *Grapholitha inopinata* Heinrich, M. TAKIZAWA (*Res. Bul. Agr. Egypt. Sta. So. Manchuria Ry. Co.*, No. 16 (1936), pp. 77-112, pls. 6, figs. 7; *Eng. obs.*, pp. 109-112).—The results of studies during the seasons of 1934 and 1935 especially on the life history of and control measures for the apple fruit borer *G. inopinata*, which is generally recognized as the most serious enemy of fruit of the apple in southern Manchuria, including Kwangtung Province, are reported. While its distribution is not definitely known, the pest appears to be confined to southern Manchuria, being most commonly present in the apple orchards south of the Gaipin Prefecture.

Studies of the red plum worm *Laspeyresia (Grapholitha) funebrana* Treit. [trans. title], P. BOVEY (*Rev. Path. Vég. et Ent. Agr. France*, 24 (1937), No. 3-4, pp. 189-317, figs. 68).—Report is made of a study of the morphology, life history, habits, and natural enemies of and means of control for *L. funebrana* conducted in Switzerland, the details being given in tables and graphs. The contribution is presented with a list of 75 references to the literature.

Field comparisons of insecticides for control of the codling moth, J. R. EYER (*New Mexico Sta. Bul.* 259 (1938), pp. 44, figs. 14).—This further report on control measures for the codling moth (*El. S. R.*, 79, p. 364) reviews the results of field spraying experiments for the control of this pest conducted at the station during the past 9 yr.

In work with lead arsenate and lead arsenate substitutes in the southern part of the State it was shown that of all of the insecticides tested only lead arsenate affords a high and consistent degree of freedom from infestation. "Where six applications, consisting of a calyx and five cover sprays, are used, a reasonable degree of protection, resulting in 85 to 95 percent of sound fruit, can be secured. With a split schedule using arsenate of lead in the first three applications and one of the more effective organic insecticides, such as oil-nicotine or phenothiazine, in the last three cover sprays, the amount of control is reduced to 65 or 75 percent. Where the arsenical applications are reduced to a calyx and one cover spray, only a very moderate degree of protection, e. g., 50 to 65 percent of sound fruit, is secured.

"Fruit receiving three applications of lead arsenate almost invariably exceeds the tolerance of arsenic residue at harvest, regardless of what supplementary materials are used, but when only two applications of lead arsenate are used the deposit of arsenic is usually below tolerance at harvest. Next to lead arsenate, aluminum silicofluoride or cryolite was the most promising insecticide tested, but Federal regulations regarding the amount of deposit at harvest likewise restrict its use to a small number of applications. Some degree of encouragement was found in the use of certain spreaders, stickers, and conditioners to increase spray deposit, particularly triethanolamine oleate and summer oil, bentonite clay, copper resinate oil, and certain proprietary colloids.

"Weather conditions, particularly dry, hot summers, apparently interfere with the efficiency of organic insecticides like oil-nicotine and phenothiazine, which,

according to other investigators, have proved to be much more promising in other regions than in New Mexico. Late frosts occasionally destroy the apple crop and during such years the codling moth population is reduced considerably, although not entirely destroyed. Control during years immediately following crop destruction is comparatively easy."

The European corn borer and corn hybrids, L. L. HUBER. (Coop. U. S. D. A. et al.). (*Ohio Sta. Bimo. Bul.* 197 (1939), pp. 26-28, figs. 3).—This article describes and identifies the areas of Ohio that appear to be most favorable to the corn borer and in which appreciable commercial damage has been caused, and discusses briefly the principles which underlie present recommendations for control.

Fifteen yr. of investigations have shown that the avoidance of abnormally early planting on well-drained, fertile soil and the use of resistant and tolerant strains of corn are the best defense against the corn borer. These two measures are relatively effective and can be applied individually. Fundamentally they are preventive measures. It is pointed out that the principles are identical with those involved in later planting. Just as borer survival is higher on early than on late-planted corn, it is also higher on early than on late-season strains. It is the difference in borers per stalk that most growers and seedsmen have in mind when they say that a certain strain is resistant to the corn borer, and this is a type of resistance associated with seasonal maturity. Resistance other than that accounted for through seasonal maturity is present in certain strains, but in general it is not of important commercial consequence.

The maize trap crop for the control of corn ear worm in cotton, W. J. S. SLOAN (*Queensland Agr. Jour.*, 49 (1938), No. 1, p. 76).—Reporting briefly upon work conducted in the experimental field the results obtained are said to have been sufficiently promising to justify a considerable extension of experimental work on a maize trap for the control of the corn earworm in cotton during the current season.

Some observations on the salivary and stomach secretion of *Anopheles* and other mosquitoes, A. DE BUCK (*K. Akad. Wetensch. Amsterdam. Proc.*, 40 (1937), No. 2, pp. 217-223).—The studies reported relate to agglutination of the red blood corpuscles by the salivary secretion of *A. maculipennis* and other mosquitoes, delay of coagulation of the blood caused by the strong anticoagulin in the salivary secretion, acceleration of coagulation of the blood resulting from a strong coagulin in the stomach secretion, and reaction of the skin.

It was found that the hemagglutinin in the salivary secretion of *A. maculipennis* is present in the median acinus only, and the salivary glands of *Theobaldia annulata* contain a weak hemagglutinin. The anticoagulin in the salivary secretion of *A. maculipennis* is present almost exclusively in the median acinus. The secretion of the posterior portion of the mid-gut of *Culex pipiens* and *T. annulata* contains a coagulin. The secretion of the lateral acini of the salivary glands of *A. maculipennis* seems to be responsible for the irritating and wheal-producing action of the saliva.

A new larvicide, W. OMAR (*Jour. Egypt. Med. Assoc.*, 19 (1936, No. 10, pp. 592-608).—The acid oil sludge which is a waste product in the oil-refining industry was found by the author to have a powerful insecticidal action on the larvae and pupae of mosquitoes (*Culex* and *Anopheles*). This property seems to be mainly due to its soluble ingredients. One part of sludge when added to 1,000 parts of water was found to kill all the developmental stages of the mosquito in a few hours. It has many advantages over other larvicides used in practice, the most important being that it is a waste product without monetary value.

Recent investigations on the buffalo fly *Lyperosia exigua* de Meijere and its parasites in north Australia, T. G. CAMPBELL (*Jour. Council Sci. and Indus. Res. [Austral.]*, 11 (1938), No. 1, pp. 77-82, fig. 1).—Observations made on the density of the buffalo fly *L. exigua* in localities in Australia where parasites (*Spalangia* spp.) have been liberated showed that they had not become established, the numbers of the flies having been found much the same as in previous years.

A laboratory method for testing tropisms of blowflies, D. J. LEE (*Jour. Council Sci. and Indus. Res. [Austral.]*, 10 (1937), No. 4, pp. 271-274, fig. 1).—A method for testing the chemotropisms of blowflies, devised during the course of work on a laboratory technic for investigation of their responses to attractants and repellents, and, particularly, attractive materials in fleece wool, is described.

A survey of the Australian sheep blowflies, I. M. MACKERRAS and M. E. FULLER (*Jour. Council Sci. and Indus. Res. [Austral.]*, 10 (1937), No. 4, pp. 261-270, fig. 1).—In an examination of 1,691 strikes from all the sheep-raising parts of Australia in the course of a survey which extended over several years, *Lucilia cuprina* was found to be the most important and widespread of the sheep flies in the Commonwealth. The species of *Galliphora*, especially *G. nociova*, are responsible for about one-fifth of the strikes, chiefly in southern districts. The English sheep fly *L. sericata* was found to be of no practical importance in Australia.

Details of the survey are presented in tables.

Studies on the sheep blowfly problem (N. S. Wales Dept. Agr., Sci. Bul. 54 (1937), pp. 126, figs. 71).—The studies here contributed are A Review of the Sheep Blowfly Problem in New South Wales (pp. 7-60) and Observations on Fleece Rot and Body Strike in Sheep, Particularly in Regard to Their Incidence, Type of Sheep Susceptible, and Economic Importance (pp. 61-95), both by H. G. Belschner; Bacterial Colouration of Wool, by H. R. Seddon (pp. 96-110); The Classification of Sheep According to Susceptibility to Blowfly Strike, by H. R. Seddon and H. G. Belschner (pp. 111-122); and Relationship of Rainfall to Crutch Strike by Sheep Blowflies (pp. 123-126).

The control of the onion fly, D. W. WRIGHT (*Jour. Min. Agr. [Gt. Brit.]*, 44 (1938), No. 11, pp. 1081-1087, pl. 1).—Observations of the life history and habits of the onion maggot in the eastern counties of England are presented. Control measures in Europe and North America are briefly reviewed and experiments involving the use of deterrents and larval poisons described. Satisfactory control was obtained by the use of calomel powder applied to the seed before planting.

Biology and control of three noxious fruitflies in Java, C. J. H. FRANSSEN (*Landbouw [Buitensorg]*, 13 (1937), No. 5, pp. 221-238, figs. 11; *Eng. abs.*, pp. 237, 238).—Of the fruitflies indigenous in Java, only three have been found to be a source of injury, namely, *Dacus ferrugineus* Coq., which may cause serious damage especially to Spanish pepper, 100 percent of the crop being at times infested, and also to mangoes, bananas, oranges, coffeeberries, etc.; *D. umbrosus* F., which has been found in jack fruit (*Artocarpus integra*) and tjampedak (*A. champeden*); and the melonfly, injurious chiefly to cucumbers, melons, and other cucurbits, and to tomatoes, papaw, and other plants.

A contribution to the knowledge of the puparia of Anthomyiidae, M. N. STORK (*Tijdschr. Ent.*, 79 (1936), No. 1-2, pp. 94-168, figs. 35).—This contribution is presented with a four-page list of references to the literature.

Control of *Hylemyia brassicae* Béhé.: Results of five years' experiments in Mory near Warsaw, Poland, J. W. RUSZKOWSKI and J. GAWINOWA (*Rocz.*

Ochrony. Roślin, 3 (1936), No. 2, pp. 136-167; *Eng. abs.*, pp. 165, 166).—The authors report upon a study of the cabbage maggot, the most injurious insect of cabbage and cauliflower crops, especially the early plants, in Poland. It is said to have appeared near Warszawa (Warsaw) in great numbers, producing 96.5 percent of infestations and 39.5 percent of dead plants. The most satisfactory control was obtained from two or three applications of corrosive sublimate.

The contribution is presented with a list of 42 references to the literature.

The chemical control of the sheep maggot fly *Lucilia sericata* Meigen, W. MOORE (*Scot. Jour. Agr.*, 20 (1937), No. 3, pp. 227-240, pl. 1).—An account is given of a dip and of a dressing which proved effective in combating *L. sericata*.

Some results of trapping the sheep blowfly *Lucilia sericata* Meigen, G. D. MORISON (*Scot. Jour. Agr.*, 20 (1937), No. 2, pp. 123-134).—Data relating to the sites in which sheep blowflies are most numerous, the number and species captured, the correlation of catch to weather and to number of sheep struck, and traps and lures are reported upon, in connection with a list of 25 references.

Catalogue of Chinese Siphonaptera, C. Y. LIU (*Lingnan Sci. Jour.*, 15 (1936), Nos. 3, pp. 379-390; 4, pp. 583-594; *Chin. abs.*, p. 594).—A systematic catalog of the Chinese fleas, including host and collection records.

A note on *Melasoma populi* L. (Chrysomelidae) as a pest of basket willows, H. G. H. KLEARN (*Jour. Bath and West and South. Counties Soc.*, 6. ser., 10 (1935-36), pp. 229-232, pl. 1).—An account is given of the life history of the chrysomelid beetle *M. populi*, the damage caused to basket willow, and methods of control, including a suggested spray program.

Catalogue of the phytophagous beetles of China, G. LIU (*Lingnan Sci. Jour.*, 13 (1934), Nos. 1, pp. 109-133; 2, pp. 239-250; 4, pp. 633-660; 14 (1935), Nos. 1, pp. 105-121; 2, pp. 285-298; 3, pp. 415-438; 4, pp. 627-637; 15 (1936), Nos. 1, pp. 19-30; 2, pp. 249-261).—This is a continuation of the catalog previously noted (*El. S. R.*, 70, p. 651).

A dangerous enemy of the vine in Morocco, *Dorystenes forficatus* F. (Coleoptera, Cerambycidae) [trans. title], R. BOUHÉLIER and E. HUDAUT (*Rev. Zool. Agr. et Appl.*, 35 (1936), Nos. 10, pp. 145-153, figs. 3; 11, pp. 173-176).—A report of a study of the cerambycid beetle *D. forficatus*, based upon observations near Boulhaut (Chaoula), Morocco.

The control of flea beetles by means of a seed dressing.—Progress report, C. L. WALTON (*Jour. Bath and West and South. Counties Soc.*, 6. ser., 10 (1935-36), pp. 206-213).—A dressing consisting of a mixture of paradichlorobenzene and naphthalene dissolved in kerosene, applied at the rate of 0.5 to 1 fluid oz. to each pound of crucifer seed sown at a cost not exceeding 2 d. per acre for materials, was found to have prevented or reduced flea beetle injuries in a considerable number of field trials despite weather conditions that were in many cases very unfavorable.

Wireworms and sugar-beet, F. R. PETHERBRIDGE (*Jour. Min. Agr. [Gt. Brit.]*, 45 (1938), No. 1, pp. 23-27, pls. 2).—In a number of preliminary experiments (aimed at establishing the first sowing of sugar beets in wireworm-infested fields) that were conducted on various farms in the eastern counties of England, best results were obtained by drilling wheat between the rows of beets. The experiments have shown that under certain circumstances it is possible to obtain a good crop of sugar beets in such fields by drilling the wheat in this way.

The coffee berry-borer in Ceylon (*Stephanoderes hampei* Ferr.), J. C. HUTTON (*Trop. Agr. [Ceylon]*, 87 (1936), No. 6, pp. 378-383, fig. 1).—Notes on the life history and habits of and control measures for *S. hampei* in Ceylon.

[Notes on the New Guinea sugarcane weevil] (*Queensland Soc. Sugar Cane Technol. Proc.*, 8 (1937), pp. 49-62, 143-152, 265-268, figs. 10).—The contributions presented include a Progress Report of Sugar Cane Beetle Borer Investigations in North Queensland, by R. W. Mungomery (pp. 49-62); Rind Hardness Determinations as an Aid in Beetle Borer Control, by J. H. Buzacott (pp. 143-152); and Conservation of Crop Residues and Its Relation to Borer Population in the Tully Area by H. G. Knust (pp. 265-268).

Borers in clove trees, L. G. E. KALSHOVEN (*Landbouw [Buitenzorg]*, 12 (1936), No. 4, pp. 165-190, figs. 6; *Eng. abs.*, pp. 189, 190).—Longicorn borers, the main pests attacking clove trees in the Dutch East Indies, include the stem borer *Hocamitodera semivelutina* Hell, a cerambycid thought to be *Opiocercus biguttatus* Donov., the Sumatra clove borer *Nothopeus (Coloborhombus) fasciatipennis* Waterh., and *Chelidonium brevicorne* Schwarzer in Malacca.

Entomological investigations (*St. Lucia Agr. Dept. Rpt.*, 1935, pp. 20, 21).—The work of the year (*E. S. R.*, 74, p. 513), with the citrus weevil (*Diaprepes* spp.) is briefly reported upon.

Beekkeeping (*Alaska Sta. Bul.* 7 [1938], pp. 27, 28).—Reference is made to the satisfactory wintering of a hive of Golden Italian bees kept in the root cellar, where darkness and a temperature of 34° F. were maintained. Thirty lb. of uncapped comb honey was a sufficient food supply for the winter months. The swarm was placed outside on April 12, and no food was provided after May 6. A production of 99 lb. of extracted honey for the season was found when weighed on October 23.

The weight of bees, nectar, and pollen loads they carry and the causes for the changes of these weights, P. RISEA (*Latv. Univ. Rak., Lauks. Fakult. Scr.*, 3 (1936), No. 1-3, pp. 1-47, figs. 28; *Eng. abs.*, pp. 42-46).—Results obtained from weighings of bees under varying weather conditions, carried on at Vecauce, Latvia, over a period of years in the apiary of the university, are reported.

On three chalcidoid parasites of cotton borer-beetles from south India, T. V. RAMAKRISHNA AYYAR and M. S. MANI (*Rec. Indian Mus.*, 39 (1937), No. 2, pp. 125-127).—*Neocatolaccus indicus* and *Euderus pempheriphila*, attacking the cotton borer beetle *Pemphres affinis* F., are described as new. *E. gossypii* Ferr., parasitic on the larva of another cotton borer beetle (*Sphenoptera gossypii* Kerr.), is recorded for the first time from south India.

Spraying for plum sawfly, with notes on red spider and thrips, F. R. PETERSENBRIDGE and I. THOMAS (*Jour. Min. Agr. [Gt. Brit.]*, 44 (1937), No. 9, pp. 858-865).—In the experiments reported a single spraying with 3 percent quassia and soft soap when the cots of Czar and damson plums were beginning to split gave a very good control of the plum sawfly *Hoplocampa flava* L. Mineral oil emulsion and derris also gave a good control, but derris and sulfonated loral was not quite so good. Mineral oil and derris was the only one of the washes to check the fruit tree red spider *Oligonychus ulmi* Koch and also the pear thrips.

The small spruce sawfly (*Lygaeonematus pini* Retz.=*Nematus abietinus* Christ) [trans. title], W. NÄGELI (*Mitt. Schweiz. Anst. Forstl. Versuchsw.*, 19 (1936), No. 2, pp. 213-331, figs. 54; *Fr. abs.*, pp. 371-375).—A monographic account presented with a list of 147 references to the literature.

Control of cyclamen and broad mites on gerbera, F. F. SMITH (*U. S. Dept. Agr. Cir.* 516 (1939), pp. 15, figs. 9).—The several species of *Tarsonemus* mites that occur on *Gerbera jamesoni* in greenhouses, except the broad mite and the cyclamen mite, appear to be saprozoic. The broad mite increases rapidly in

numbers and causes severe diseaselike dwarfing and curling of leaves and abortion and decolorization of flower rays. Dusting infested plants with sulfur is an effective control. The cyclamen mite occurs more generally but in smaller numbers. Foliage injured by the cyclamen mite develops bronzed patches and slight curling. Flowers are rendered valueless by deformation of rays. Sprays, dusts, and fumigants have not controlled this mite on gerbera. Both the cyclamen mite and the broad mite may be destroyed by immersing plants arranged in thin layers on a wire tray at transplanting time for from 15 to 20 min. in water at 110° F. or by a 30- to 60-min. exposure to vapor heat at 110°. Successful control of mites depends upon aseptic methods to prevent reinfestation. Gerbera varieties differ in tolerance to treatment from 25- to 40-min. immersion in water or from 60- to 120-min. exposure to vapor heat. The most resistant varieties were severely injured or killed by 30-min. immersion in water at 116° for control of the root-knot nematode *Heterodera marioni* (Cornu). Chemical dips for disease control were generally injurious when used in conjunction with heat treatment for mites.

The control of sheep ticks, W. L. STEWART (*Jour. Roy. Agr. Soc. England*, 97 (1936), pp. 81-95, pls. 2, figs. 4).—This contribution deals with the castor-bean tick, which constitutes a serious menace to sheep rearing in upland areas of England through the transmission of louping ill and tick-borne fever and is responsible for much wastage in lambs due to septic infections. A new anti-tick dip consisting of an arsenic-carbolic mixture, incorporating a natural greasy compound and used at a strength of 0.17 percent arsenious oxide, was tested and appeared to act as a deterrent against reinfestation. It is suggested that this dip may be used to control ticks without unduly upsetting the ordinary routine of sheep management.

Ticks infesting domestic animals in Southern Rhodesia, R. W. JACK (*Rhodesia Agr. Jour.*, 33 (1936), No. 12, pp. 907-929, figs. 3; 34 (1937), No. 1, pp. 25-37).—A revision of an earlier account (*E. S. R.*, 59, p. 777), including the life history, habits, relation to animal diseases, and measures employed for tick control.

ANIMAL PRODUCTION

The American Society of Animal Production: Record of proceedings of the thirty-first annual meeting, November 25-27, 1938 (*Amer. Soc. Anim. Prod. Proc.*, 31 (1938), pp. 380, figs. 34).—This is a report of the annual meeting held at Chicago in 1938 (*E. S. R.*, 79, p. 664). The following papers were presented before the dairy cattle, horses and mules, beef cattle, swine, sheep and wool, meats, and nutrition sections:

One Cause of Fat Variation in Milk, by E. B. Powell (pp. 40-47); Effects of Climatic Factors on Livestock, by F. R. Edwards (pp. 48-53) (*Ga. Expt. Sta.*); The Distribution of Elements of Fertility Between Feces and Urine in Dairy Cattle, by K. E. Harshbarger and W. B. Nevens (pp. 58-61) (*Univ. Ill.*); Effect of Decreased Body Reserves of Vitamin E on the Reproduction of Goats, by G. K. L. Underbjerg, B. H. Thomas, and C. Y. Cannon (pp. 62-67) (*Iowa*); A Discussion of Winter Feeding of Kentucky Thoroughbreds, by G. D. Buckner, E. S. Good, and A. Harms (pp. 73-76) (*Ky.*); Progress Report—Work Stock Project in the State of Georgia, by M. P. Jarnagin (pp. 83-86) (*Univ. Ga.*); Carotene Requirements for Fattening Beef Cattle, by J. H. Jones, J. K. Riggs, G. S. Fraps, J. M. Jones, H. Schmidt, R. E. Dickson, P. E. Howe, and W. H. Black (pp. 94-102) (*Tex. Expt. Sta. and A. and M. Col. and U. S. D. A.*); Reducing the Corn and Increasing the Hay Content of Rations for Fattening Yearling Steers, by P. Gerlaugh and C. W. Gay (pp. 107-109); Creep-Feeding

March and April Calves That Are To Be Finished in Dry Lot After Weaning, by B. R. Taylor, L. E. Hawkins, and O. S. Willham (pp. 110-112) (Okla.); Ration of Sow and Response of Suckling Pigs, by A. G. Hughes (pp. 332, 333) (Calif.); The Utilization of the Nitrogen of Urea and Ammonium Bicarbonate by Growing Calves, by E. B. Hart, G. Bohstedt, H. J. Deobald, and M. I. Wegner (pp. 333-336) (Univ. Wis.); Shape of the Growth Curve as a Controlling Factor in Conformation and Anatomical Composition of the Animal Body—Swine, by C. P. McMeekan (pp. 337-341); Food Value and Metabolic Unit of Body Size, by M. Kleiber (pp. 341, 342) (Univ. Calif.); and Meat and Meat Products as Sources of Essential Dietary Factors, by C. A. Elvehjem (pp. 343-350) (Univ. Wis.).

[Livestock investigations in Alaska] (*Alaska Sta. Bul.* 7 [1938], pp. 12-17, 22, 23, 28-30, figs. 6).—Studies for which results are reported include the value of oat-and-pea silage as a sole ration for milking cows; the effect of temperature on the keeping quality of silage in a trench silo; the value of oat-and-pea

hay as a sole ration for fattening pigs; rations for dairy calves; a comparison of stake-cured oat-and-pea hay, artificially dehydrated oat-and-pea hay, artificially dehydrated oat-and-vetch hay, and alfalfa hay for milking cows; and a comparison of unchopped oat-and-pea hay, chopped oat-and-pea hay, and chopped wild beach hay for wintering sheep.

[Investigations with livestock in Georgia]. (Partly coop. U. S. D. A.). (*Georgia Coastal Plain Sta. Bul.* 29 (1938), pp. 40-75, figs. 4).—Progress reports (E. S. R., 80, p. 85) are presented for the following lines of investigations: The returns secured by grazing steers on variously fertilized lowland and upland permanent pastures, various types of annual summer and winter pastures, and kudzu; the returns secured by winter grazing of corn and velvetbeans and green oats with the beef breeding herd; the production of feeder calves and veal calves; the management of brood sows and their litters; a year-round grazing system for hogs; and the returns secured from hogging off corn, runner peanuts, and sweetpotatoes. The second year's results of previously described steer fattening trials are reported in detail.

[Livestock investigations by the Nebraska Station] (*Nebraska Sta. Cir.* 60 (1939), pp. 56-72, figs. 6).—A brief résumé of outstanding accomplishments in beef cattle, swine, and sheep feeding investigations, meat quality studies, poultry feeding and management studies, and the production and manufacturing of dairy products is recorded.

Papers presented at meeting of Texas Agricultural Workers' Association, Fort Worth, Texas, January 13, 14, 1939 (*Tex. Agr. Workers' Assoc. Mtg., Papers 1939*, [pp. 93-104, 110-121, 127-140, 164-166]).—The following papers are among those presented before the annual meeting: Carotene Requirements of Dairy Cattle, by O. C. Copeland (pp. 93-97), Vitamin and Mineral Requirements of Poultry, by R. M. Sherwood (pp. 98-101), On the Way Toward Tender Meat, by S. Cover (pp. 102-104), Mineral Deficiency Studies with Lambs and Range Cattle, by J. M. Jones (pp. 110-114), Cattle Feeding Experiments, by J. H. Jones (pp. 115-117), Primitive Sheep and Their Relation to Modern Sheep and Wool Production, by B. L. Warwick and S. P. Davis (pp. 118-121), A Parade of Some Texas Swine Experiments, by F. Hale (pp. 127-130), Some Factors Affecting the Body and Texture of Texas Butter, by F. E. Hanson (pp. 131-133), and Range and Pasture Research in Texas, by R. L. Hensel (pp. 164-166) (all *Tex. Expt. Sta.*); and Wildlife Conservation in the Farm and Ranch Program, by W. P. Taylor (pp. 134-140) (*Tex. A. and M. Col., U. S. D. A., et al.*).

[Livestock and poultry investigations in western Washington], M. W. and V. L. MILLER, G. E. BEARSE, and C. F. McCLARY (*Western Washington Sta. Rpt.* 1938, pp. 5, 6, 33-35, 37, 38).—In addition to reports of investigations previously noted (E. S. R., 81, p. 255), information is presented on the influence of various cereals and oat hulls in chick rations on the incidence of cannibalism; the value of various supplements to breeding hen rations on hatchability, chick mortality, and chick growth; and the effect of packaging materials and treatments and humidity conditions during shipping on egg quality.

Factors influencing the apparent energetic efficiency of productive processes in farm animals, S. BRODY. (*Mo. Expt. Sta.*). (*Jour. Nutr.*, 17 (1939), No. 3, pp. 235-251).—A comprehensive review, with particular reference to (1) the influence of body size on apparent efficiency of milk production, egg production, growth, and muscular work; (2) the influence of endogenous and exogenous factors on apparent gross efficiency; and (3) the principle of optimal and limiting factors in efficiency. Twenty-seven references are cited.

The distribution of orally administered arsenic in the tissues of animals, with special reference to its partition in rat blood, J. S. McHARGUE

and M. LYONS. (Ky. Expt. Sta.). (*Ky. Acad. Sci. Trans.*, 7 (1935-37), pp. 70, 71).—The blood of albino rats, guinea pigs, rabbits, and chickens, all of which had received a ration containing 250 p. p. m. of arsenic, was found to contain 1,300, 7, 5.2, and 4 p. p. m. of arsenic, respectively. The high content in rat blood was found to be almost entirely in the cells and appeared to be chemically combined with the hemoglobin molecule.

The physiological significance of small amounts of arsenic: Effect on erythrogenesis, J. S. McHARGUE and W. K. HALL. (Ky. Expt. Sta.). (*Ky. Acad. Sci. Trans.*, 7 (1935-37, p. 89).—Preliminary studies, in which albino rats were fed a stock ration to which was added 9 p. p. m. of sodium arsenate, gave evidence that arsenic stimulates erythrogenesis in this species, although the mechanism by which stimulation occurs was not determined.

Cobalt in nutrition, B. W. FAIRBANKS. (Univ. Ill.). (*North Amer. Vet.*, 20 (1939), No. 3, pp. 33-38).—A comprehensive review with 36 references is cited.

Skeletal storage of fluorine in the growing rat fed bone meals of varying fluorine content, R. J. EVANS and P. H. PHILLIPS. (Wis. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 1, pp. 188-191).—Confirming previous findings (E. S. R., 70, p. 231), it was found that bonemeal prepared from the bones of veal calves was very low in fluorine (average 20 p. p. m.), while meals prepared from mature cattle bones and commercial bonemeals ranged from 474 to 550 p. p. m. Feeding tests with rats indicated a much greater deposition of fluorine in the femurs of growing rats receiving the high fluorine bonemeals than in cases where the veal calf bonemeal was fed. There was also evidence that a part of the fluorine in the calf bonemeal was in a form not readily available for absorption and storage in the skeleton of the rat.

Chondroitin sulfuric acid as a growth factor, H. E. ROBINSON, R. E. GRAY, F. F. CHESLEY, and L. A. CRANDALL (*Jour. Nutr.*, 17 (1939), No. 3, pp. 227-233).—Continuing this line of investigation (E. S. R., 81, p. 263), tests with both chicks and rats gave evidence that chondroitin sulfuric acid serves as a growth factor for this species, a 3-percent level apparently being optimal in the basal ration used. It was shown that this material is not identical with the antidermatosis factor found in rice polish filtrate.

The lactation-promoting effect of l-cystine when fed with alfalfa proteins, L. D. WRIGHT and J. R. HAAG. (Oreg. Expt. Sta.). (*Jour. Nutr.*, 17 (1939), No. 3, pp. 263-268, fig. 1).—In a series of tests in which lactating rats were fed synthetic rations containing alfalfa leaf meal as the source of protein (approximately 9 percent of crude protein), the addition of 0.4 percent l-cystine to the ration markedly enhanced its lactation-promoting properties as indicated by the rate of growth of nursing litters of young.

Simplified rations for guinea pigs suitable for assay of the grass juice factor, G. O. KOHLER, S. B. RANDLE, C. A. ELVFILJEM, and E. B. HAERT. (Wis. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 2, pp. 154-157, fig. 1).—In further studies (E. S. R., 79, p. 667), efforts were directed toward developing a purified ration which could replace mineralized winter milk as a basal ration in assaying for the grass-juice factor. A ration composed of dextrin, crude casein, salts, brewers' yeast, cod-liver oil, cottonseed oil, Snowdrift, and butterfat 59:18:4:6:1:2:5:5 or a similar ration in which 12 parts of lard replaced the cottonseed oil, Snowdrift, and butterfat in the above mixtures proved satisfactory for studying the grass-juice factor and also a second nutritional factor described as the stomach-ulcer factor.

Evaluation of the vitamin A potency of feeds, G. S. FRAPS. (Tex. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 9, pp. 525-527).—

This discussion deals with the precursors of vitamin A in feeding stuffs and various methods for estimating the vitamin A potency of feeds.

Stability of vitamin B₁ of vacuum-dried animal tissues during storage, A. ARNOLD and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Food Res.*, 3 (1938), No. 4, pp. 367-372, figs. 2).—Using the chick-assay procedure, fresh stocks of vacuum-dried beef kidney, beef spleen, beef lung, and hog brains were found to contain 5, 2, 2, and 1.6 International Units of vitamin B₁ per gram, respectively. Assays of these same materials after 2 years' storage in vacuum-packed cans showed varying degrees of loss in antineuritic potency. Very little loss occurred in the beef spleen, while small but significant losses ranging up to a maximum of 20 percent occurred in the other materials.

Assay of vitamin K concentrates, S. A. THAYER, R. W. MCKEE, S. B. BINKLEY, D. W. MACCORQUODALE, and E. A. DOISY (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 3, pp. 478-481, fig. 1).—A curative method of assay of vitamin K, using chicks depleted of vitamin K reserve and based on Trevan's principles of bio-assay, is described. A unit of the vitamin is defined as that quantity which produces a clotting time of 10 min. or less in 50 percent of a group of 10 or more chicks which have been fed a diet practically devoid of vitamin K for 14 days immediately following hatching.

Conference on Cooperative Meat Investigations—State agricultural experiment stations, United States Department of Agriculture, and the livestock and meat industry, participating; Report of review committee, I, II ([*Chicago: Natl. Livestock and Meat Bd.*], 1937, vols. 1, pp. [540]; 2, pp. [454], [fig. 1]).—At the 1935 conference on cooperative meat investigations a review committee was authorized and given the responsibility for preparing reviews and summaries of both published and unpublished meat research results which had been produced by cooperating institutions since 1925. The report of this committee is now available in two mimeographed volumes, including approximately 450 abstracts. Volume 1 contains reports on methods, beef, and pork, and vol. 2 reports on lamb, grade and measurements, cookery, lard, and nutrition.

Effect of a pellagra-producing diet on Herbivora, P. B. PEARSON, II. SCHMIDT, and A. K. MACKAY. (Tex. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 3, pp. 423-425, fig. 1).—Six lambs, from 2 to 3 mo. of age, were placed on a diet of regenerated cellulose, yellow corn, peas, unpurified casein, and dicalcium phosphate 20 : 60 : 10 : 9 : 1, with salt ad libitum and vitamins A and D supplied by percomorph oil. Aside from a temporary setback after 4 or 5 weeks on this ration, the lambs developed normally during the course of the trial. Since this diet consistently caused cessation of growth and produced pellagra-like symptoms in pigs and blacktongue in dogs, it is concluded that nicotinic acid is either not a dietary essential for lambs or that their requirements are much lower than for the above-named species.

Cattle feeding, 1937-1938, J. H. SKINNER and F. G. KING (*Indiana Sta. Bul.* 433 (1938), pp. 12).—In trials involving seven lots of 2-year-old feeder cattle, the rations were designed to give information on (1) the value of cottonseed meal in a ration of shelled corn, corn silage, and oat straw; (2) the value of a ration containing ground ear corn and shelled corn; and (3) mixed protein supplements compared to cottonseed meal. A comparison of cattle receiving a basal ration of shelled corn, corn silage, and oat straw with those receiving a supplement of cottonseed meal in addition to this ration indicated that the supplement added a markedly beneficial result in gains and finish of the cattle and increased the net returns over the feed costs. A comparison of groups which received shelled corn, ground ear corn, and a mixture of shelled and ground ear corn (4:5), respectively, in addition to cottonseed meal, silage,

and oat straw indicated that the cattle on ground ear corn made more rapid gains and sold at a higher price than those receiving shelled corn, while those receiving the mixture gained more rapidly but did not reach a higher finish than those on shelled corn. Gains on hogs following the cattle and the value of pork per steer after deducting the cost of extra feed was materially higher in the shelled corn lot than the ground ear corn. A comparison of four groups receiving protein supplements of (1) cottonseed meal, (2) cottonseed meal, linseed meal, and soybean oil meal, equal parts, (3) a complex protein mixture plus minerals, and (4) the same as group 3, less minerals, indicated that the mixed supplements had only a very slight advantage over cottonseed meal alone in rate of gain or finish of cattle. Cattle receiving the complex mixture plus minerals slightly excelled the other groups in selling value.

Chemical analysis and probable cause of urinary calculi formed in a yearling bull. G. D. BUCKNER and E. S. GOOD. (Ky. Expt. Sta.). (*Ky. Acad. Sci. Trans.*, 7 (1935-37), p. 68).—In the case reported autopsy of a yearling bull revealed a large number of urinary calculi in the kidneys, urethra, and bladder. Chemical tests showed that these calculi were composed mainly of ammonium magnesium phosphate with some calcium phosphate. Faulty metabolism is listed as the probable cause.

Managing farm flock sheep for greater profit in southern Idaho. C. E. FAYRE and T. D. PHINNEY. (Coop. U. S. D. A. et al.). (*Idaho Sta. Bul.* 228 (1939), pp. 16, figs. 3).—In an attempt to determine the causes for the instability of permits to graze farm sheep flocks on national forest summer range, a comparison was made of the results obtained from farm flocks grazed in cooperative bands on summer range v. yearlong farm flocks. The summer ewe losses averaged 5.3 and 3.4 percent, the summer lamb losses averaged 6.6 and 1.7 percent, the average weight of lambs produced per ewe was 57.9 and 67 lb., and the annual returns per ewe were \$1.41 and \$3.04 for the cooperative bands and yearlong farm flocks, respectively. The net receipts per lamb were 38 ct. greater, the receipts from wool per ewe 17 ct. greater, and the total expense of operation per ewe was \$1.01 less in the farm flocks. With a yield of 3 tons of alfalfa hay per acre of irrigated land, the hay would have to sell for \$8.12 per ton to equal the returns secured by grazing the eight ewes and their lambs per acre of irrigated pasture under the conditions of this test.

Changes in meat and wool characteristics resulting from the use of pure-bred mutton rams on native ewes. J. E. FOSTER and E. H. HOSTETLER (*North Carolina Sta. Tech. Bul.* 60 (1939), pp. 27, figs. 9).—Detailed studies were made of the quality and quantity of meat and wool secured from the offspring of (1) native ewes by native rams, (2) native ewes by purebred Shropshire and Hampshire rams, (3) second-, third-, and fourth-generation females from group 2 by purebred rams in each instance, and (4) purebred Hampshire ewes and rams. The first-cross ewes by both Shropshire and Hampshire rams were materially heavier, both as yearlings and when mature, and produced heavier fleeces of longer staple than the native ewes. The second crosses did not show an increase in live weight or fleece weight over the first crosses, but all showed improvement in body conformation and quality and in quality of wool. The Hampshire crosses excelled the Shropshire crosses in weight but did not show as much quality, while the Shropshire crosses excelled both in weight and quality of fleece. Purebred Hampshire lambs made most rapid gains, followed in order by Hampshire crosses, Shropshire crosses, and natives. The Shropshire crosses were much larger, deeper, and wider but not higher than the natives, while the Hampshire crosses were larger and higher but not wider or deeper than the Shropshire crosses, and the purebred

Hampshires were larger in every respect than the other breeds. The native carcasses, both lamb and mature, were markedly inferior to the others in finish, color of lean and fat, and marbling, while the Shropshire crosses slightly excelled the Hampshire crosses in these factors.

Silicon content of wool in relation to dietary silicon, A. R. PATTON (Arkansas Sta. Bul. 375 (1939), pp. 15).—Two groups of four Hampshire sheep each were fed rations containing 0.7 and 4.7 percent silica, respectively, over a 10-mo. experimental period, the high silica content being supplied by replacing a portion of alfalfa hay in the low silica diet with ground rice hulls. Monthly wool samples were analyzed for silica. Samples from the low silica group began at a mean level of 0.019 percent, increased to a maximum of 0.03 percent at the end of 3 mo., and then gradually decreased to 0.005 at the end of the 10-mo. period, while samples from the high silica group started at 0.024, rose to 0.072, and then declined to 0.008 percent. The relatively small differences in silica content of the samples was considered insufficient to establish any influence of dietary silica on the silicon in the wool. Silica determinations on 81 species of grasses showed a range from 0.3 to 4.9 percent.

Canned dog food as a source of energy for dogs, C. J. KOEHN. (Ala. Polytech. Inst.). (Vet. Med., 34 (1939), No. 2, pp. 108-111, figs. 2).—Chemical analyses of 23 samples of commercial canned dog feeds showed a range from 1.3 to 4.9 in nutritive ratio and from 0.77 to 3.31 calories per gram in total calorific value. A feeding trial in which 7 brands of canned feeds were each fed as a sole diet to American foxhound pups over a 26-week experimental period showed that the average daily consumption of feed per pup ranged from 3.1 to 4.8 lb. Three of these brands proved to be a complete diet, 1 was deficient in vitamin D, 1 deficient in calcium, and 2 were of extremely poor nutritional quality. Young pups required about three times as much feed per unit of body weight as the same individuals at maturity, and the body requirements of bitches were approximately doubled during lactation. In practically all cases, specific feeding directions on the package failed to recommend sufficient amounts to meet the total nutritive requirements of dogs.

The utilization of the energy of feed by growing chickens, G. S. FRAPS and E. C. CARLYLE (Texas Sta. Bul. 571 (1939), pp. 44).—Productive energy of a basal mixture of feed based on 11 experiments involving 256 chicks is reported. Representative chicks were analyzed at the beginning of the test, and all chicks were analyzed for protein and fat at the end of the test. The gains in energy of the chicks, the quantity of feed consumed, and the length of the feeding period gave data from which the maintenance requirement of the chicks and the productive energy of the feed were calculated. Individual chicks varied appreciably in their capacity to grow and to utilize feed. Maintenance requirements and productive energy, calculated on the assumption that maintenance requirement varied according to live weight, varied less and were in closer agreement with values reported by other investigators than when calculated on the assumption that maintenance requirement varied according to the surface area of the bird. The average maintenance requirements of chickens from 28 to 42 days old was 74.8 gm. of total feed, 63.3 gm. of effective organic constituents, 48.7 gm. of effective digestible nutrients, 134 calories of productive energy or 200 calories of metabolizable energy. The ration averaged 1.79 calories of productive energy per gram of feed, 2.14 calories per gram of effective organic constituents, and 2.77 calories per gram of effective digestible nutrients, and 67.6 percent of the calories of metabolizable energy over maintenance was used for productive purposes. An average of 25.8 percent of a limited (about one-half) ration and 42.1 percent of a full-fed ration was used for gain in weight.

The utilization of food elements by growing chicks.—VII, A comparison of corn and kalo in a ration for growing chicks, C. W. ACKERSON, M. J. BLISH, and F. E. MUSSEHL (*Nebraska Sta. Res. Bul.* 109 (1939), pp. 8).—Continuing this series of studies (E. S. R., 81, p. 93), the effect of replacing 31 percent of ground corn in a chick growing ration by 31 percent of ground kalo was studied in a growth and body analysis experiment with newly hatched chicks, in which the feed intake of the two lots was kept identical by the hand-feeding of pelleted rations. No significant differences in rate of growth or in the percentage reduction of nitrogen, calcium, and phosphorus was evident at the end of a 6-week trial. Some instances of wing and toe picking occurred in the kalo-fed lots.

A study of the cell content of the blood of normal chickens, with special reference to comparative differential leucocyte counts made with supravital and Wright's staining technics, N. M. TWISSELMANN. (Univ. Calif.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 151-159, fig. 1).—The mean values, standard deviations, and the range of variability within normal limits for total erythrocyte, total leucocyte, and differential leucocyte counts for 21 chickens, as obtained by the supravital and by the Wright method of staining, are presented and these values compared with other published values. Wide variations were found in successive differential counts of the same individual as well as between individuals, indicating the misleading conception that may be gained from a limited number of observations.

The non-fermentable reducing substance of chicken blood, J. W. CAVETT (*Poultry Sci.*, 18 (1939), No. 2, p. 150).—To ascertain whether the relatively high normal blood sugar level in chickens was primarily due to glucose or partially to non-sugar-reducing material, the non-fermentable-reducing substance in the whole blood, plasma, and cells of 21 chickens was determined. The data presented indicate that the high blood sugar was not due to the latter substance.

The influence of bile on erosions of the chick gizzard lining, H. J. ALMQUIST and E. MECCHI. (Univ. Calif.). (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 407-412).—Extending these studies (E. S. R., 80, p. 90), it was established that cholic acid is an effective dietary supplement in the cure or prevention of erosions of the gizzard lining and that dehydrocholic acid is almost as effective, while desoxycholic acid is comparatively ineffective in this regard. A deficiency of bile or cholic acid in the chick leads to gizzard erosions.

Some observations on the skeletal development of fowl to six weeks of age, H. E. LEMASURIER and H. D. BRANTON (*Poultry Sci.*, 18 (1939), No. 2, pp. 114-122, figs. 4).—Data are presented on the weekly growth rate of New Hampshire, Barred Plymouth Rock, and White Leghorn chicks which indicated that both male and female chicks of each breed grew more rapidly and were heavier at 6 weeks of age when raised in batteries with 24-hr. lighting than when raised on the floor. X-ray photographs of representative chicks from each lot indicated more extensive calcification of the skeletal tissue of the battery-reared chicks. However, this increased degree of calcification was not in relative proportion to the remainder of the body growth, resulting in a coarse heavy bone, whereas birds raised on the floor showed a very desirable skeletal growth in keeping with other body development, resulting at 6 weeks in a finely textured and finished bone. Certain questions are raised regarding the present criteria and standards for the measurements of calcification and skeletal growth.

A new factor required for growth and reproduction in the domestic fowl, J. C. BAURENFEIND, A. E. SCHUMACHER, A. Z. HODSON, L. C. NORRIS, and G. F. HEUSER. (Cornell Univ.). (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 1, pp. 108-111).—In trials with chicks involving the use of a heated diet

adequate in all known vitamins except the antidermatosis factor and nicotinic acid, it became evident that supplementing this diet with the above factors resulted in a significantly slower rate of growth than was obtained by feeding the unheated diet. Similarly in trials with laying hens, feeding the heated diet supplemented with the antidermatosis factor or nicotinic acid resulted in very low hatchability of eggs as compared with the unheated diet. An unidentified factor which corrected the above-described deficiencies was provided in yeast, milk, and cereals. The factor was destroyed by heating in a dry atmosphere for 36 hr. at 120° C. It appeared improbable that it was identical with the grass-juice factor or that it was of a protein nature.

The antidermatosis vitamin required for reproduction in the domestic fowl, J. C. BAUERNFEIND and L. C. NORRIS. (Cornell Univ.). (*Science*, 89 (1939), No. 2314, pp. 416, 417).—In an experiment to determine the requirements of mature chickens for the antidermatosis vitamin, the evidence obtained indicated that within the limits of this test a lack of this factor did not affect egg production or mortality but that its presence was required for hatchability or reproduction. Hens receiving the heated experimental diet deposited less of the antidermatosis vitamin in their eggs than hens fed a normal diet, as indicated by the relative susceptibility of their chicks to a deficiency of this factor.

Vitamin A requirements of laying hens, H. J. ALMQUIST and E. MECOMI. (Univ. Calif.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 129-137).—Six groups of hens of tested egg-producing ability were maintained on experiment for 1 yr. (July 9 to July 9). The basal ration for the various groups was supplemented as follows: 1, check; 2, 3, and 4, carotene in oil to supply 1,800, 3,600, and 7,200 International Units of vitamin A; and 5 and 6, shark-liver oil to supply 1,800 and 3,600 I. U. of vitamin A per pound of ration, respectively. Data are reported on the feed consumption, percentage mortality, egg production, hatchability of fertile eggs, vitamin A storage in the livers of hens at the end of the trial, and the growth rate and survival of chicks for the 6 groups. The lower level of carotene feeding proved inadequate for satisfactory hatchability, while an equal level of vitamin A units supplied by shark-liver oil allowed satisfactory hatchability. Rat assays at the end of the trial indicated that the carotene supplement had lost approximately one-third of its original vitamin A activity. A ration containing the lower level of shark-liver oil calculated to contain 2,027 I. U. of vitamin A per pound of feed appeared to represent about the minimum dietary level of vitamin A, which was satisfactory for all purposes. These results, along with recent findings of other investigators, led to the conclusion that about 2,500 I. U. of vitamin A per pound of feed may be considered as a minimum practical recommendation for poultry feeding.

The availability of manganese in avian digestion, H. S. WILGUS, JR., and A. R. PATTON. (Colo. Expt. Sta.). (*Science*, 89 (1939), No. 2313, p. 393).—A series of in vitro experiments which consisted of precipitating calcium phosphate from solutions containing calcium, phosphate, and manganous ions in known amounts approximating the concentration which produces perosis in chicks gave evidence that the manganese was carried down quantitatively by the calcium phosphate precipitate. Similar results were obtained by precipitating ferric chloride solution containing manganous ions. These results were substantiated by in vivo experiments using White Leghorn pullets by showing that manganese in the digestive tract, in the excreta, and even in the feed was rendered markedly less diffusible by the use of excessive amounts of bone-meal. These findings support the hypothesis that the perosis-producing action of calcium phosphate and ferric citrate is at least partially due to the removal

of manganese from solution in the intestinal tract either by adsorption or chemical combination.

Assimilation and storage of manganese in the developing embryo and growing chick, W. D. GALLUP and L. C. NORRIS. ([N. Y.] Cornell Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 99-105).—A study of the assimilation of manganese by the developing chick embryo revealed that approximately 75 percent of the manganese in the egg was taken up by the embryo during incubation. The greatest concentration of manganese per unit of dry weight occurred at the ninth day (0.613 mg. per 100 gm.), while the most rapid accumulation of manganese occurred between the ninth and fifteenth days of incubation. In growing chicks, both on the low-manganese and manganese-supplemented diets, the absolute amount of manganese increased during the first 5 days, but no further increases occurred until about the twenty-fourth day. There was considerable decrease in the manganese content of the livers of the former lot during the first 5 days, followed by a slight increase, while that of the latter group remained quite constant. Depletion of liver stores did not occur until the chicks were over 6 weeks of age, after which the liver content was roughly in proportion to the manganese intake. The manganese content of the bones declined rather rapidly, particularly in the former group, indicating that the manganese requirement of the liver is met first and that of the bones second.

Some effects of manganese on eggshell quality, M. LYONS (*Arkansas Sta. Bul.* 374 (1939), pp. 18, figs. 6).—A detailed study was made of the eggshell quality of approximately 5,200 eggs produced by six pens of pullets receiving rations varying in amounts and sources of manganese and containing varying amounts of calcium and phosphorus. Pullets fed low manganese rations (7 p. p. m.) with either high or low levels of calcium and phosphorus produced eggs with distinctly different and inferior shell characteristics than those fed adequate amounts of manganese. When a number of pullets on the manganese-deficient diets were changed to manganese-adequate diets, a rapid and marked improvement in shell quality occurred, while pullets changed from adequate to deficient-manganese levels showed an even more rapid decrease in eggshell quality. Rations containing 27 p. p. m. of manganese proved inadequate in some cases for the production of high quality eggshell, while 57 p. p. m. appeared entirely adequate. Manganese supplied in rice bran appeared equally as effective as manganous sulfate. Normal eggshells contained less than 0.00002 percent manganese.

Comparative nutritive value of firm and watery egg albumen, N. B. GUERANT and W. J. RUDY. (Pa. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 2, pp. 166-169, fig. 1).—Two series of rat feeding tests, in which dried whole eggs containing varying proportions of firm and watery albumen plus calcium carbonate ad libitum constituted the sole diet, gave evidence that there is no significant difference in the nutritional value of firm and watery egg albumen.

A study of the effect of green feed upon interior egg quality, R. C. RINGROSE and C. L. MORGAN. (S. C. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 125-128).—A determination of the height of firm albumin, percentage of firm albumin, and yolk index of eggs produced by comparable pens of White Leghorn pullets confined and allowed access to green feed, respectively, indicated that the presence of green feed in the ration did not affect the quality of the eggs.

Effect of high temperatures for short periods on the quality of infertile eggs, M. W. OLSEN. (U. S. D. A.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 123, 124).—Three comparable lots of infertile eggs were incubated at 90° F. for

24 hr., incubated at 100° for 18 hr., and unincubated, respectively, and then stored at 35°. At the end of 7 days the loss in weight and the percentage of thick and thin albumin were determined for each lot. Only slight differences occurred in percentage moisture loss for the different lots. The eggs contained an average of 53, 52, and 61.5 percent of thick albumin, respectively, after storage, but aside from this variable condition the incubated eggs kept as well in storage as did the control eggs.

The care of layers in batteries, D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bmo. Bul.* 197 (1939), pp. 29-34, figs. 3).—Feeding and watering equipment for laying battery installation, rations for layers in batteries, and methods of feeding are each briefly discussed. A comparison of the livability and egg production of pullet layers in batteries v. similar pullets in floor pens (average 25 trials) indicated a lower percentage of mortality and an average of 7 eggs per bird greater production in favor of those in batteries.

DAIRY FARMING—DAIRYING

Early cut artificially dried hays for dairy cows, O. M. CAMBUEN and C. H. JONES (*Vermont Sta. Bul.* 446 (1939), pp. 8).—In further studies (E. S. R., 74, p. 677), various artificially dried young immature roughages were used to replace grain in the ration of milking cows. The results of two trials indicated that cows receiving corn silage and a full allowance of the artificially dried grass hay but no grain produced milk as efficiently as when fed silage, a limited quantity of the same quality hay, and a half allowance of grain, thus indicating the possibility of lessening production costs through the feeding of such high quality hays.

Physiology of dairy cattle, I, II (*Jour. Dairy Res.* [London], 10 (1939), No. 1, pp. 133-164).—Continuing this series (E. S. R., 73, p. 689), part 1, Reproduction and Lactation, by J. A. B. Smith (pp. 133-152), and part 2, Nutrition, by S. Morris (pp. 153-164), give comprehensive reviews of recent developments within these specific fields of dairy science. References to the literature include 171 citations in the first review and 100 in the second.

Glucose infusion through the external pudic artery, W. E. PETERSEN and W. L. BOYD. (Minn. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 37 (1937), No. 3, pp. 537-539).—Following previous attempts to influence lactose secretion by intravenous or intramammary duct injections of sugar (E. S. R., 75, p. 332), isotonic solutions of glucose were introduced into the external pudic artery. No consistent increases in lactose content of the milk occurred after such infusions of sugar, leading to the conclusion that the lactose content of milk is not increased by increasing the glucose content of the arterial blood.

The energy content of goat milk, V. E. PETERSON, C. W. TURNER, and N. P. RALSTON. (Mo. Expt. Sta.). (*Jour. Nutr.*, 17 (1939), No. 3, pp. 293-301, figs. 3).—The energy value, fat, nitrogen, lactose, inorganic and total phosphorus, and total solids are reported for 18 samples of goat's milk collected at various stages of lactation. One lb. of 4-percent goat's milk contained an average energy value of 342.28 calories. Energy value could be estimated with considerable accuracy from the percentages of protein, lactose, fat, or total solids. Within a fat range of 3.5 to 5.5 percent the equation $y=9.564x+39.618$ gave the energy value with considerable accuracy, and when the percentage of total solids was known the equation $y=7.035x-21.632$ gave very accurate estimates of energy values.

Studies of lipase action, I-III. (Cornell Univ.). (*Jour. Dairy Sci.*, 22 (1939), No. 3, pp. 127-152, figs. 21).—Three phases of this study are reported.

I. *Lipase action in normal milk*, B. L. Herrington and V. N. Krukovsky (pp. 127-135).—By determining the free fatty acids in the fat phase of numerous individual cow and mixed milk samples, it was found that the fat lipolysis occurred in practically all raw milk samples. Milk from different cows showed a narrow range in the acidity of the fat at the time the milk was drawn from the udder, but after a few hours wide variations occurred. An appreciable increase in free fatty acids occurred between the time of afternoon milking and the time of delivery to a pasteurizing plant the following morning. Rapid cooling tended to retard the rate of lipase action. It appeared that milk contains two lipases, one of which was completely inhibited by a very small amount of formalin while the other was not significantly inhibited by moderate amounts of formalin.

II. *The activation of milk lipase by temperature changes*, V. N. Krukovsky and B. L. Herrington (pp. 137-147).—Further studies indicated the pronounced effect of temperature changes on lipolytic activity. Lipolysis in cold milk was accelerated by warming the milk slightly and recooling, and within the temperature range studied the length of time milk was held at the precooling temperature or at the activating temperature was of less importance than the actual temperatures employed. Maximum activation was obtained by precooling to 5° C., rewarming to 30°, and then recooling to below 10°. Milk which had been activated could be reactivated or deactivated by suitable heat treatment.

III. *Lipase action in the milk of individual cows*, B. L. Herrington and V. N. Krukovsky (pp. 149-152).—A study of lipolysis in the milk of 61 individual cows showed much variation in the rate of lipolytic action and in the response of different samples to activation by warming and cooling. However, no correlation could be established between rate of lipolysis and stage of lactation, stage of gestation, or level of milk production. Most samples contained both the formalin-tolerant and formalin-sensitive enzymes, although the ratio varied.

Studies on the activated flavor of milk, J. C. FLAKE, K. G. WECKEL, and H. C. JACKSON. (Univ. Wis.). (*Jour. Dairy Sci.*, 22 (1939), No. 3, pp. 153-161).—Continuing this line of investigation (E. S. R., 77, p. 841), samples of milk subjected to various treatments were irradiated with a strong ultraviolet source and were tested for intensity of activated flavor development. Heating milk to temperatures above 150° to 160° F. and cooling enhanced the activated flavor when such milks were subsequently irradiated. Better results were secured when irradiation preceded homogenization when both processes were used. Altering the "salt balance" of milk failed to influence the intensity of activated flavor, while additions of nitrogen and oat flour inhibited the development of this flavor. Oxidation of milk samples tended to remove the activated flavor. Further evidence was secured to indicate that the protein fraction of milk is the parent substance of this off-flavor. The activated flavor due to the intense ultraviolet irradiation was shown to be practically identical with the burnt flavor which develops in milk exposed to sunshine.

A further study of the production of milk of abnormal composition by cows free from udder streptococci, E. G. HASTINGS and B. A. BEACH. (Wis. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 53 (1939), No. 7, pp. 543-556).—The observations reported in a previous paper (E. S. R., 77, p. 386) regarding the production of abnormal foremilk by cows free from udder streptococci have been extended during the second lactation for some of these animals. Of the 13 animals studied further, 9 which produced abnormal milk during the first lactation were abnormal in the second, while the 4 animals which had normal histories during the first lactation were normal during the second. No more

definite statement as to the cause of this disturbance or the transmissibility of its cause can be made as a result of the further study. The disturbance tended to continue from one lactation to another in the same quarters. It also tended to decrease production and to shorten the production period and to provide a more favorable udder environment for the establishment of streptococci. Its influence on the composition of milk was generally slight.

Productivity of media containing milk for recently isolated strains of the coliform group, M. T. BARTHAM and L. A. BLACK. (Univ. Md.). (Jour. Bact., 37 (1939), No. 4, pp. 371-375).—Two strains each of *Escherichia*, *Aerobacter*, and intermediates isolated from raw milk were inoculated into five liquid and seven solid media in addition to standard lactose broth and standard methods agar. The productivity of the liquid media in order of descending sensitivity was (1) methylene-blue bromocresol purple, (2) fuchsin lactose, (3) brilliant-green bile, (4) formate ricinoleate, and (5) Eijkman medium. None of these proved as productive as standard lactose. The productivity of the solid media ranked as follows: (1) Neutral-red bile, (2) violet-red bile, (3) Endo, (4) brilliant-green lactose bile, (5) lactose taurocholate, (6) desoxycholate, and (7) trypanflavine agar. Counts obtained on neutral-red bile and violet-red bile were considerably higher than those on standard agar plus milk.

The occurrence of *Streptococcus zymogenes* in the intestines of animals, F. R. SMITH. (Univ. Calif.). (Jour. Dairy Sci., 22 (1939), No. 3, pp. 201, 202).—The isolation of *S. zymogenes* from the feces of the horse and the cow is reported. The fact that this organism appears to be a normal inhabitant of the bovine intestine is of significance in connection with its occasional occurrence in milk.

Controlling milk pasteurization efficiency through the use of the phosphatase test, A. J. HAHN and P. H. TRACY. (Univ. Ill.). (Jour. Dairy Sci., 22 (1939), No. 3, pp. 191-200, figs. 2).—A study of the applicability of the Schärer modification of the phosphatase test for determining the efficiency of pasteurization of milk gave evidence that variations of 1° F. temperature or 5 min. in the holding period or the addition of 0.1 percent raw milk to the pasteurized sample could be detected by this technic. Homogenization had no effect on the phosphatase enzyme, and the use of mercuric chloride as a preservative did not affect the accuracy of the phosphatase test. A photoelectric method for more accurately determining color values in the test is described.

The present status of the resazurin test, J. M. FRAYER (Vi. Dairy Plant Oper. and Mgrs. Assoc., Short Course Conf. and Ann. Mtg., 17 (1938), pp. 5-14).—A summary essentially confirming an earlier report by the author (El. S. R., 70, p. 531).

"Summit" folding milk-sampling plunger, W. R. BLACK ET AL. (Brit. Min. Agr. and Fisheries, Agr. Mach. Testing Com. Certif. and Rpt., 70 (1939), pp. 6, fig. 1).—A folding-type milk-sampling plunger is described. Advantages of this device as determined at the National Institute for Research in Dairying are (1) high efficiency of mixing milk for sampling, (2) convenience of handling during the process of plunging, (3) ease of cleaning, and (4) portability.

Accounting for butterfat, E. O. HERREID (Vi. Dairy Plant Oper. and Mgrs. Assoc., Short Course Conf. and Ann. Mtg., 17 (1938), pp. 27-32).—Various factors affecting the estimation of butterfat by the Babcock method are discussed.

A skunk-like odor of bacterial origin in butter, T. J. CLAYDON and B. W. HAMMER. (Iowa Expt. Sta.). (Jour. Bact., 37 (1939), No. 3, pp. 251-258).—In a series of unsalted butter samples held at 21° C. to test keeping quality, three samples from a single plant developed a skunk-like odor after from 2 to 4

days in storage. When pasteurized sweet cream was inoculated with the defective butter and churned at pH values ranging from 5.0 to 7.5, this defect was reproduced. The causative organism was isolated and its morphology and cultural characteristics are described. The name *Pseudomonas mephitica* is suggested for it. Salt had an inhibiting effect on the production of this defect, but thorough working of the salted butter was necessary to prevent its appearance. Inoculating the butter wash water with this organism reproduced the defect in unsalted butter.

A soft cheese of the Bel Paese type, R. R. FARBER (*U. S. Dept. Agr. Cir. 522* (1939), pp. 19, figs. 14).—This circular presents detailed directions for manufacturing, curing, and wrapping of Bel Paese type cheese, with information on its composition, keeping qualities, appearance, and other characteristics.

Dextrose in commercial ice-cream manufacture, W. J. CORBETT and P. H. TRACY (*Illinois Sta. Bul. 452* (1939), pp. 345-380).—A series of studies was conducted to determine the adaptability of dextrose for use in commercial creams, the effect of dextrose on certain physical and chemical properties of the ice cream mix, and consumer preference for part-dextrose v. all-sucrose ice cream. In most instances one-fourth of the sucrose was replaced by dextrose. The dextrose imparted more color to the mix, slightly lowered the pH, and decreased the mix viscosity. At this level dextrose did not affect the time required to freeze or whip the mix, and the optimum drawing temperature was about 1° lower than for the all-sucrose. There was little difference in the body and texture of the two ice creams when frozen in batch freezers, but when the continuous freezer was used the amount of stabilizer in the dextrose mix had to be reduced to avoid a sticky body. The dextrose ice cream melted somewhat faster at room temperature, and a lower dipping temperature was preferable for this product than for the sucrose ice cream.

Studies on members of the Escherichia-Aerobacter group isolated from Kansas ice cream, F. E. NELSON, B. F. DIAMOND, and W. J. CAULFIELD. (Kans. State Col.). (*Jour. Bact.*, 36 (1938), No. 5, p. 568).—A high percentage of ice cream samples tested gave positive results for the presence of the *Escherichia-Aerobacter* group of organisms. When these positive samples were subjected to the phosphatase test for pasteurization efficiency about one-fourth were positive to both tests while three-fourths were phosphatase negative, indicating contamination after pasteurization or the presence of resistant strains. All organisms of this group were killed by 30 minutes' exposure at 142° F. with skim milk as the suspension medium, but 12 *Escherichia* survived the exposure when suspended in ice cream, suggesting the need of higher pasteurization temperatures for ice cream than for milk.

Some properties of milk powders, with particular reference to sweet buttermilk powders, R. N. DAVIS. (Univ. Ariz.). (*Jour. Dairy Sci.*, 22 (1939), No. 3, pp. 179-189).—Twenty samples of various kinds of milk powders manufactured under known conditions were studied with reference to acidity, moisture, solubility, fat content, and hygroscopic properties. A low moisture content was shown to be essential to good keeping quality. Powders produced by the drum-dryer process absorbed less moisture than those produced by the spray process. Moisture absorption varied indirectly with the fat content of the powder. Skim milk powder absorbed less moisture than sweet buttermilk powder, which in turn absorbed less than sour buttermilk powder. The sour buttermilk powder also retained more moisture than the sweet under desiccation. Moisture equilibria levels of different powders at various humidity levels are indicated. Spray-process sweet buttermilk powders were practically all dispersible in water at 135° F., and the original dispersibility was retained for prolonged periods when powders were held in a desiccator. Small amounts

of acid in the buttermilk lowered the dispersibility of the resultant powder. Buttermilk powders held at refrigeration temperature had a higher dispersibility after 1 yr. of storage than those held at room temperature. High storage temperatures also encouraged discoloration of the powders.

Detecting thermophilic contamination in skim-milk powder, C. M. SORESENSEN (*Food Res.*, 3 (1938), No. 4, pp. 421-427).—In attempts to overcome the difficulty from undissolved powder and heat-coagulable material encountered when water dilutions of skim milk powder were plated for bacterial counts, tests were conducted using N/60 sodium or lithium hydroxide as dilution media in place of distilled water. An average for 15 samples of skim milk powder showed that slightly greater thermophilic spore counts were observed on plates made from these N/60 alkali dilutions than from water dilutions of the same powder, and a difficulty in counting due to undissolved flakes and specks was eliminated in the former method. Definite advantages in using the alkali dilution media were secured also when plating skim milk powder on dextrose-tryptone agar containing bromocresol purple, since the pH of average milk powder solution is sufficiently low to impair the usefulness of the indicator in detecting acid colonies when ordinary water-dilution methods were employed.

Certain practical aspects of the use of paper milk containers, P. H. TRACY. (Univ. Ill.). (*Jour. Milk Technol.*, 1 (1938), No. 3, pp. 40-42).—The type of paper milk container which is formed and paraffined immediately before filling is discussed with respect to its advantages and disadvantages over glass bottles and to consumer reaction as based on 221 complete questionnaires returned by milk customers on the university milk route. The majority of users preferred the paper to the glass from a sanitary point of view and because the paper containers took up less space in the refrigerator and were more convenient for picnics. The glass bottle was preferred for greater ease of pouring and separating the cream from the skimmed milk. Few thought there was any difference in the flavor of the milk, its keeping quality, its tendency to freeze, or the rate of temperature rise. A slight majority preferred the paper container to the glass when the milk was sold for the same price, but at 1 ct. less, 75 percent preferred the paper container.

VETERINARY MEDICINE

Livestock diseases and sanitation (*Nebraska Sta. Cir.* 60 (1939), pp. 52-55, fig. 1).—A brief discussion of the work of the station since its organization.

An improved method for testing antiseptic dusting powders, J. H. BREWER (*Jour. Bact.*, 37 (1939), No. 4, pp. 411-413, fig. 1).—A description is given of the simple method of testing antiseptic dusting powders which closely simulates the actual conditions of use. It requires the additional use of masks made from 3 x 5 filing cards and a small piece of fine mesh gauze. "This test eliminates false results due to concentration of essential oils, standardizes the zone of application of the dusting powder, and thereby unifies the results for comparison."

Oat hay poisoning, W. B. BRADLEY, O. A. BEATH, and H. F. EPPSON. (Univ. Wyo.). (*Science*, 89 (1939), No. 2312, p. 365).—Preliminary investigations indicate that the toxicant found in oat hay or oat straw that is occasionally responsible for the poisoning of cattle in western Wyoming is formed during the oat-plants development.

Nitrate as the cause of oat hay poisoning, W. B. BRADLEY, H. F. EPPSON, and O. A. BEATH. (Wyo. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 541, 542).—Experiments conducted indicate that potassium nitrate may be the cause of oat hay poisoning in livestock.

Is there always poison in sorghum \times Sudan grass crosses? C. F. ROGERS, W. L. BOYD, and A. H. LARSON. (Univ. Minn.). (*North Amer. Vet.*, 19 (1938), No. 6, pp. 30-32, figs. 2).—The authors are led to conclude that the danger from hydrocyanic acid poisoning might be increased if sorghum were crossed with Sudan grass. This, however, would not result unless the cross be made with true sorghum plants or plants shown to have an increased hydrocyanic acid content.

The anaerobic bacteria and their activities in nature and disease: A subject bibliography, I, II, E. MCCOY and L. S. MCCLUNG (*Berkeley: Univ. Calif. Press*, 1939, vols. 1, pp. XXIII+295; 2, pp. XI+602).—Volume 1 of this work consists of a chronological author index and volume 2, a subject index. The material assembled in the two volumes consists of approximately 120,000 entries from about 10,500 original journal articles, monographs, or other published reports. Most of these have been examined in the original and scanned for reference to the appropriate subject sections. The arrangement of material in volume 2 is as follows: Habitat or occurrence (pp. 1-38), culture methods (pp. 39-56), morphology (pp. 56-63), metabolism (pp. 63-81), products of metabolism (pp. 81-103), physiology (pp. 104-130), serological studies (pp. 131-169), disease relations (pp. 170-398), classification (pp. 399-574), and special lists (pp. 575-585).

Observations of anaplasmosis as it occurs in Puerto Rico, H. L. VAN VOLKENBERG. (P. R. Expt. Sta.). (*Vet. Med.*, 34 (1939), No. 4, pp. 254-256).

Chronic arthritis in wild mammals, being a description of lesions found in the collections of several museums and from a pathological service, H. FOX (*Amer. Phil. Soc. Trans.*, n. ser., 31 (1939), No. 2, pp. [1]+73-148, pls. 12, figs. 2).—Report is made of an analysis of more than 1,700 skeletons and autopsies of wild animals which reveals in the joints changes that correspond with chronic arthritis in man. Not only has this been discovered in specimens exhibited in menageries but also in material that was certainly in its proper wild habitat when killed. The lesions of these "truly wild" animals are entirely comparable to those from captive specimens, and it is evident, therefore, that chronic arthritis occurs in nature. There is no apparent relationship between arthritis and taxonomic position, zoogeography, ecology, habits, diet, pathological panels, and focal infection. There is a strongly suggested similarity between the arthritis of the lower mammals and that of the deforming and rheumatoid arthritides in man.

Heterophile antigenicity of *Brucella abortus*, D. F. HOLTMAN. (Ohio State Univ.). (*Jour. Bact.*, 37 (1939), No. 2, pp. 231, 232).—In the course of experimentation, the authors found evidence that certain strains of *B. abortus* can stimulate in rabbits the formation of antibodies capable of agglutinating or hemolyzing sheep red blood cells. "Two cultures of *B. abortus*, isolated from supraspinous bursitis in horses, possessed this property even after 100 transfers on an agar medium free of heterophile antigen. Two cultures isolated from cattle failed to demonstrate heterospecificity, although a third culture of bovine origin, after several years of growth on horse serum agar, was able to induce heterophile antibody formation in rabbits. Since the horse provides a rich source of Forssman antigen, an agent lacking in cattle, it seems probable that the heterospecificity of the bacteria was acquired not only from the living animal but also from culture media incorporating its serum."

Some observations on the phagocytosis of *Br[ucella] abortus* by polymorphonuclear leucocytes, F. W. PRIESTLEY (*Vet. Rec.*, 50 (1938), No. 53, pp. 1793-1797, fig. 1).

Effects of sulfanilamide on *Brucella melitensis*, var. *melitensis*, abortus, and suis. E. E. MENEFEE, JR., and M. A. POSTON (*Jour. Bact.*, 37 (1939), No. 3, pp. 269-276, fig. 1).—In reviewing the literature the authors have found that in all cases of brucellosis reported every patient that responded well to sulfanilamide therapy had a high agglutinin titer before the chemotherapy was commenced. The results obtained by the authors in sulfanilamide-treated guinea pigs support the clinical observations in suggesting that the bacteriostatic action allows the normal defense mechanisms of the animal to cope adequately with the invading bacteria.

Equine encephalitis in man (*Amer. Jour. Pub. Health*, 29 (1939), No. 3, pp. 272-274).—A brief review presented with a list of eight references.

The viability and immunizing value of egg-propagated laryngotracheitis virus. F. R. BEAUDETTE and C. B. HUDSON. (N. J. Expt. Stas.). (*Vet. Med.*, 32 (1937), No. 10, p. 457).—Tests have shown that continued propagation of laryngotracheitis virus in eggs does not change the immunizing power of the virus.

On the hydrogen-ion concentration of myiotic wounds and its relation to the oviposition stimulus in *Cochliomyia americana* O. and P., E. W. LAAKE. (U. S. D. A.). (*Amer. Jour. Trop. Med.*, 19 (1939), No. 2, pp. 193-197, figs. 3).—This contribution on myiasis reports on the determination of the H-ion concentration of exudates of wounds infested with the larvae of the screwworm and the apparent relationship between H-ion concentration and the oviposition stimulus of the fly. The results indicate that a certain degree of acidity is a prerequisite to the healing of a postmyiotic wound.

A study of rat pneumonia. D. BORDEN and W. L. KULP. (Conn. State Col.). (*Jour. Bact.*, 37 (1939) No. 3, pp. 351, 352).—A small Gram-negative motile bacillus was isolated from the lungs and heart blood of rats in the acute stage of pneumonia. "This organism appears to be identical with *Bacillus bronchisepticus* both morphologically and biochemically. Serologically it has been determined that antigenic differences exist between the organism isolated from infected rats and known strains of *B. bronchisepticus*. The organism in question also shares certain antigenic components with an organism recently isolated by Eldering and Kendrick and temporarily named by them *B. para-pertussis*. Success has been obtained in 100 percent of the attempts to induce rat pneumonia by the intratracheal method of inoculation. The histopathology of the lungs of artificially infected rats appears to be identical with those of spontaneous cases. It has been found that the rat pneumonia organism, *B. bronchisepticus*, and *B. para-pertussis* each produce a substance which is capable of oxidizing dimethyl paraphenylene diamine hydrochloride."

Studies on rabies. P. REMLINGER and J. BAILLY (*Études sur la rage. Paris: Masson & Co., 1938, pp. 174, [fig.] 1*).—Twenty-one chapters are given in this account of rabies, with a chronological index of work conducted at the Pasteur Institute of Tanguier and of Istanbul (Constantinople) from 1903 to 1937, inclusive.

Infection of chicks and chick embryos with rabies. J. R. DAWSON, JR. (*Science*, 89 (1939), No. 2309, pp. 300, 301).—Preliminary observations of chicks and chick embryos inoculated with rabies virus indicate that the chick embryo brain is an ideal medium for its propagation.

A note on the monophasic non-specific *Salmonella* types. D. W. BRUNER and P. R. EDWARDS. (Ky. Expt. Sta.). (*Jour. Bact.*, 37 (1939), No. 4, pp. 365-370).—The authors have found the technic of Wassén, who described the method for the separation of specific and nonspecific phases based on the immobilizing effect of homologous immune serum, to be an excellent means of isolating phases of *Salmonella* which are suppressed under ordinary conditions of culture. By

its use specific phases have been isolated from all of the so-called nonspecific *Salmonella* types.

Human toxoplasmosis: Occurrence in infants as an encephalomyelitis verification by transmission to animals. A. WOLF, D. COWEN, and B. PAIGE (*Science*, 89 (1939), No. 2306, pp. 226, 227).—A protozoan morphologically identical with *Toxoplasma*, which was found at autopsy in lesions of an infant that had succumbed to encephalomyelitis and was transmitted to rabbits and mice, is named *T. hominis*, with the reservation that it may later prove to be identical with one or all of the animal strains.

Differences in clinical pictures of transit fever and haemorrhagic septicæmia. J. P. PICKERING (*Vet. Rec.*, 51 (1939), No. 9, pp. 277-279).

The epidemiology of *Trichinella spiralis* infestation and measures indicated for the control of trichinosis. W. H. WRIGHT (*Amer. Jour. Pub. Health*, 29 (1939), No. 2, pp. 119-127, figs. 2).—The author is led to conclude that the role of the rat as a source of swine trichinosis has been largely overemphasized.

The cultivation of *Tritrichomonas foetus* in developing chicken eggs. N. D. LEVINE, C. A. BRANDLY, and R. GRAHAM. (Univ. Ill.). (*Science*, 89 (1939), No. 2303, pp. 161, 162).—In work designed to ascertain the possibility of propagating certain protozoa in developing chicken embryos it was found that *T. foetus* actually multiplies in eggs rather than merely survives. Twenty-two serial transfers from egg to egg of bacteria-free protozoa were made over a period of about 3 mo., with a multiplication factor of about 30 at each transfer. The trichomonads were found to survive in allantoic fluid placed in cotton-plugged test tubes for several days at room temperature, but in the egg death of the embryo may be followed very shortly by mortality of the protozoa. Preliminary experiments indicate that eggs which have been incubated about 12 days are more satisfactory for cultivation of *T. foetus* than eggs incubated for shorter or longer periods. An incubation temperature of 37° C. is better than 34.5° or 39°.

Precipitins for the tuberculin proteins of acid-fast bacteria. J. MCCARTER, E. M. KANNE, and E. G. HASTINGS. (Wis. Expt. Sta.). (*Jour. Bact.*, 37 (1939), No. 4, pp. 461-469).—The authors found the tuberculin proteins of the human, the bovine, and the avian tubercle bacilli to be distinguishable by the precipitin test. "The tuberculin proteins of the avian tubercle bacilli isolated from the chicken, the cow, and the hog, and the protein of the Johne's bacillus cannot be differentiated by the precipitin test. The tuberculin proteins of two so-called saprophytic acidfast bacteria, one isolated from the cow and one from the hog, are distinguishable from each other and from the proteins of the tubercle bacilli and of the Johne's bacillus. The precipitin test with tuberculin proteins as antigens is useful in identifying unknown acidfast bacteria when considered in conjunction with cultural and pathogenic characteristics. Further purification of the protein solutions seems necessary before the precipitin test can replace other methods of identification of acidfasts."

A historical chronology of tuberculosis. R. M. BURKE (*Springfield, Ill.: Chas. C. Thomas* [1938], pp. VIII+84).—In this chronology the progress of knowledge of tuberculosis in man and the domestic and other animals is presented under the headings of the ancient period (5000 B. C.—A. D. 1600), pre-modern period (1600-1800), and modern period (1800 to the present time). A graphic outline of the development of our knowledge of tuberculosis is given in an infolded chart. A bibliography of three pages and name and subject indexes are included.

The udder streptococci of eighteen dairy herds. J. FERGUSON. (Cornell Univ.). (*Jour. Bact.*, 37 (1939), No. 2, p. 223).—In a mastitis survey of 18 dairy herds containing 655 cows, which included the examination of quarter milk

samples for the presence of streptococci, 21 percent were found infected. Of the 229 cultures "isolated from as many quarters 160 (70 percent) were *Streptococcus agalactiae*, 16 (7 percent) were *S. dysgalactiae*, 25 (10.8 percent) were *S. uberis*, 13 (5.6 percent) were of other types, and on the remaining 15 cultures (6.5 percent) no tests were made. . . . In those herds in which *S. agalactiae* was present, it was the predominating organism and the infection tended to be widespread. Infections due to other streptococci appeared to be sporadic in origin."

The effect of sulfanilamide on the streptococci in the udder of mastitis cows, H. BAUER and M. F. GUNDERSON. (Univ. Nebr.). (*Jour. Bact.*, 36 (1938), No. 5, p. 567).—In experiments in which eight cows affected with chronic mastitis were treated with doses of sulfanilamide ranging from 0.5 to 16 oz. over a period of from 12 hr. to 22 days, the drug was found to exert a transient effect on the streptococci. As long as the drug could be detected in the milk the streptococcal count remained low and in some instances disappeared. However, as soon as the udder was cleared of the drug the streptococci reappeared in numbers as great as before treatment was begun. One of the eight cows was infected with staphylococci; the drug showed no effect on these organisms.

The bactericidal effect of sulfanilamide upon beta hemolytic streptococci in vitro, H. J. WHITE and J. M. PARKER (*Jour. Bact.*, 36 (1938), No. 5, pp. 481-498, figs. 4).—"Bactericidal action upon 36 strains of β -hemolytic streptococcus recently isolated from human infections has been demonstrated with 20 mg. percent sulfanilamide in vitro at 40° C. in peptone-glucose broth and in whole blood. Preliminary results indicate that this streptococcal action can be demonstrated in vitro with lower concentrations of sulfanilamide. Under our experimental conditions, bactericidal action due to sulfanilamide could not be demonstrated at test temperatures lower than 39°. Experimental evidence indicates that the action of sulfanilamide in vitro is delayed for at least 3 hr."

Studies of an atypical strain of *Brucella abortus* isolated from a naturally infected animal, E. E. HAMANN and I. F. HUDDLESON. (Mich. Expt. Sta.). (*Vet. Med.*, 34 (1939), No. 4, pp. 232, 233).—An atypical strain of *B. abortus* was found to be responsible for reactors in a herd of 50 Jersey animals, new reactors developing despite frequent testing and immediate disposal of all reactors. In vaccination work this atypical strain was found to be an intermediate rough form which does not produce an agglutination reaction in experimental laboratory animals or cattle. During 10 yr. of study it has never been found to establish itself in any species of animal.

Calfhood vaccination against Bang's disease.—I, Effect on agglutinin titres and results of first pregnancies, J. G. HADDENBEGH (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 479-488).—The subcutaneous administration to calves of so-called "strain 19 *Brucella* vaccine," prepared and furnished by the U. S. D. A. Bureau of Animal Industry, was followed by no serious systemic effects. There was local swelling and some elevation of temperature, but both of these effects were transient and subsided without incident. "Single injections of the vaccine caused a pronounced agglutinin response which usually reached a peak in about 10 days and then gradually diminished. In 80 percent of 625 vaccinated heifers whose agglutinin titers were studied, the test became completely negative within 4 to 6 mo. In about 20 percent, a low titer of 1:50, or partial in 1:100, was maintained indefinitely. These low titers have not been found to be associated with any permanent 'infection' with the strain 19 culture. Only 1 heifer in the group of 625 retained a positive blood test indefinitely. In 124 first pregnancies in vaccinated heifers, there were 7 abortions, or 5.6 percent. Only 3 of these abortions were ascribed to *Brucella* infection, or 2.4 percent of the pregnancies. In 64 first pregnancies in control heifers, there were 4 abor-

tions, or 62 percent, all of which were apparently due to *Brucella* infection. A number of heifers in the 1935 series developed positive blood titers due to natural exposure to infection. The disposals of this account, including positive aborters, in the vaccinated group amounted to 9.8 percent, and in the control group to 20.5 percent."

A study of hemorrhagic septicemia bacterin and Bang's disease of cattle, C. H. KITSELMAN and H. F. LIENHARDT. (Kans. State Col.). (*Vet. Med.*, 32 (1937), No. 10, p. 448).—An abstract of a contribution relating to work in which it was found that, while cattle injected subcutaneously with hemorrhagic septicemia bacterin gave rise to agglutinins for *Pasteurella* organisms, they do not give rise to agglutinins for *Brucella* organisms. In an experiment in which abortus Bang reacting cows were given hemorrhagic septicemia bacterin subcutaneously the Bang-titer of these cows was not lowered from a positive to a negative level during the 6-mo. period of observation.

An ictero-hemoglobinuria-like disease in Florida, M. W. EMMEL and D. A. SANDERS. (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 543, 544).—Report is made of the occurrence of a disease resembling bacillary ictero-hemoglobinuria in the station dairy herd. It is said to be the first time a disease of this type has been reported in Florida.

Some factors affecting the agglutinability of streptococci associated with bovine mastitis, W. N. PLASTRIDGE, L. F. WILLIAMS, and L. BANFIELD. ([Conn.] Storrs Expt. Sta.). (*Jour. Bact.*, 37 (1939), No. 3, p. 352).—An abstract of a contribution presented in December 1938. All of the ingredients, especially the kind of peptone used in preparing nutrient broth, were found to have a pronounced influence on agglutinability of udder streptococci.

The cultural and clinical significance in bovine mastitis of nonhemolytic streptococci that ferment aesculin, R. B. LITTLE (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 496-500).—The author reports upon the results of observations on the cultural and clinical significance of group III streptococci in a small self-contained herd of cows from which the animals infected with group I streptococci had been eliminated.

Potassium permanganate reduction test for mastitis, E. R. CARLSON. (Wis. Expt. Sta.). (*Vet. Med.*, 34 (1939), No. 3, pp. 160, 161).—A description is given of the potassium permanganate reduction test for mastitis. Two standard solutions for making the test (M/40 and M/200) have been prepared for field and laboratory use. In the reactions of this test the depth of color is indicative of the degree of abnormality of the milk. A code for recording these reactions is also given. The test is simple, inexpensive, informative, and can be made in the field at the time of the physical examination, when the information it reveals is most useful.

Tuberculin purified protein derivative (P. P. D.) in the double intradermal test in cattle.—Preliminary observations, R. F. MONTGOMERY and A. THOMSON (*Vet. Rec.*, 51 (1939), No. 8, pp. 229-236).—A report is made upon the use of tuberculin purified protein derivative (P. P. D.) prepared from a human strain of the tubercle bacillus employed in testing 426 cattle by the double intradermal method. "It is [concluded] that P. P. D. possesses advantages over the tuberculin previously used and should be included in any future investigation of the potency of tuberculin for use in the double intradermal test. With a sufficiently potent suitable tuberculin a single injection into the skin of the neck may detect as many reactors as does the double intradermal test."

Filarial dermatosis of sheep, H. E. KEMPER. (U. S. D. A.). (*North Amer. Vet.*, 19 (1938), No. 9, pp. 36-41, figs. 2).—Account is given of an affection of sheep apparently due to the presence of the larval stage of *Blaesophora*

schneideri within the layers of the skin. These microfilariae were not found in healthy appearing portions of the skin of affected sheep at some distance from the visible lesions but were present in all skin lesions regardless of their location on the sheep. In 11 of 12 sheep showing characteristic skin lesions the mature worms were found in the arteries on post-mortem examination. Fuadin appeared to be specific in the treatment of the skin lesions when 88 cc. or more was injected intramuscularly in 4 cc. minimum daily doses.

Observations on the stiff lamb problem with special reference to white muscle disease, L. R. VAWTER and E. RECORDS. (Nev. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 489-491).—The authors have found that all the diseases included under the category of stiff lambs are preventable if proper attention is given to sanitary precautions and methods of feeding and management of the ewes both prior to and after lambing. Treatment and remedial measures instituted after any of the enumerated diseases appear in a band of lambs has not proven wholly satisfactory. The term stiff lambs, as applied by sheepmen, "is a collective term actually embracing several separate diseases and infections such as those caused by *Actinomyces necrophorus*, *Corynebacterium pyogenes*, *Erysipelothrix rhusiopathiae*, *Clostridium tetani*, and 'white muscle' disease. Regardless of the nature of these diseases, one of the first symptoms noticed by sheepmen is lameness or stiffness."

Hemorrhagic septicemia in Indian buffaloes, T. TOPACIO (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 492-495, figs. 3).—Report is made of an outbreak of hemorrhagic septicemia in Indian buffaloes, the first in this animal to have been recorded from the Philippines.

Babesia bovis Starcovici 1893 as the cause of red-water in an Indian buffalo, J. A. IDNANI (*Indian Vet. Jour.*, 15 (1939), No. 3, pp. 247-250, pl. 1).—This contribution records the occurrence in an indigenous buffalo of a species of *Babesia* different from *B. bigemina*, the only form previously known to cause bovine redwater in India. It resembles *B. bovis*.

The hemoglobin content of the blood of pigs, L. H. SCHWARTZ. (Iowa State Col.). (*Vet. Med.*, 34 (1939), No. 5, pp. 300-304, figs. 4).—

Some tests with crystal-violet vaccine for prevention of hog cholera, B. H. EDGINGTON and A. F. SCHALK. (Ohio Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 501-509).—In experiments reported the outstanding feature was the difference in resistance to cholera manifested by "animals in the immunity tests conducted 14 to 40 days and those made at 75 to 90 days, following vaccine administration. A summary of the results of this phase of the tests shows that, of the 36 pigs subjected to hog cholera virus injections, 14 to 40 days following their vaccine treatment, none showed reactions of questionable severity. While in a group of 46 pigs subjected to cholera exposures 75 to 90 days following vaccine treatment, 12 gave undoubtedly severe reactions and 12 others died. Pen association of 40 to 50 cholera-susceptible pigs with vaccine-treated pigs, for a period of approximately 30 days after vaccine administration, gave no evidence of spread of hog cholera infection by the vaccine-treated pigs."

Equine breeding hygiene, W. W. DIMOCK. (Univ. Ky.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 469-478).

Experimental use of sulfanilamide in equine therapy, J. J. ARNOLD. (Mich. State Col.). (*Vet. Med.*, 34 (1939), No. 5, pp. 286-291).—In experiments conducted sulfanilamide proved to be of some value in acute septicemia and less so in chronic conditions. "The findings did not disprove the possibility that it may have some effect in checking the spread of infection and preventing complications. The drug appeared to be relatively nontoxic in repeated small doses, or in single large doses, but to have a cumulative effect in some cases

when large doses were repeated. Reduction of body temperature appeared to be a frequent effect of the administration of sulfanilamide, although in some cases repeated heavy doses resulted in an abrupt rise of temperature."

Aujesky's disease, P. REMLINGER and J. BAILLY (*La Maladie d'Aujesky*. Paris: Masson & Co., 1938, pp. [8] + 204, figs. 16).—This monographic account is presented in 15 chapters and includes a bibliography of 6 pages.

Infectious equine encephalomyelitis, J. FARQUHARSON. (Colo. State Col.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 459-465, figs. 3).—This discussion of symptoms, treatment, and prevention of equine encephalomyelitis is based upon work in Colorado, which State has escaped the disease in only 1 yr. since 1932. The use of chick-embryo vaccine has been found highly effective as an immunizing agent, not only as a preseasonal vaccination but also during an epizootic.

The pathology of eastern equine encephalomyelitis in the guinea pig, L. S. KING (*Amer. Jour. Path.*, 14 (1938), No. 5, pp. 636, 637).—An abstract of a contribution in which special attention was paid to the pathological findings of the central nervous system in the early stages of the disease before symptoms were apparent and in which it was found that the virus passes directly from the blood into the brain tissue. The presence of lesions in the cerebral cortex with intact subcortical centers was held to exclude nerve transmission. Under certain conditions the virus may travel along nerve paths.

Equine encephalomyelitis virus (eastern type) isolated from ring-necked pheasant, H. VAN ROEKEL and M. K. CLARKE. (Mass. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 466-468).—Equine encephalomyelitis was observed in two ring-necked pheasants received from the New Jersey Stations and identified as due to the eastern type of the virus. The English sparrow was shown by experimental inoculation to be highly susceptible to the virus, and is added to the list of hosts that may contract the disease.

Pyæmia in foals caused by *Corynebacterium equi*, H. MAGNUSSON (*Vet. Rec.*, 50 (1938), No. 44, pp. 1459-1468, figs. 7).—This contribution supplements the earlier account (*El. S. R.*, 50, p. 685).

Treatment of equine strongylidosis with *n*-butyl chloride.—Preliminary note, P. D. HARWOOD, P. C. UNDERWOOD, and J. M. SCHAFFER. (U. S. D. A.). (*North Amer. Vet.*, 19 (1938), No. 7, pp. 44-46). The drug *n*-butyl chloride, known to be effective as well as nontoxic when used as an anthelmintic against ascarids and hookworms in dogs, was tested on 3 horses. "At a dose rate of 0.1 cc. per pound of body weight (=3.5 fluid oz. per 1,000 lb.), administered in 10 times its volume of linseed oil, [it] removed more than 99 percent of the cyclostomes as well as 74 percent and 100 percent, respectively, of the *Strongylus* spp. from 2 horses. *n*-Butyl chloride used at a dose rate of 0.075 cc. per pound of body weight (=2.5 fluid oz. per 1,000 lb.), administered in 8 times its volume of linseed oil, removed 95 percent of the cyclostomes from 1 horse; this horse harbored no *Strongylus* spp. In the 3 horses tested the only symptoms observed were temporary reduction of appetite, which may have been due to excessive purgation by linseed oil, and a slight skunklike odor which appeared in the breath and emanated from the skin of the 3 subjects."

Canine distemper and vitamin A of shark liver oil, D. A. SANDERS and L. L. RUSOFF. (Fla. Expt. Sta.). (*Vet. Med.*, 34 (1939), No. 3, pp. 174-176, figs. 4).—Experiments conducted have shown that vitamin A present in shark-liver oil did not protect puppies against injections of canine distemper virus. No difference was noted in the susceptibility of the control and shark-liver oil groups to injection of canine distemper virus. "The temperature curves show that all 13 puppies had a significant rise in body temperature following

exposure to distemper virus. These results are not in agreement with Frohring's,* in which only one pup died of 25 that received excessive amounts of vitamin A and were inoculated with an untested virus of canine distemper."

Sulfanilamide as a treatment for salmon poisoning in dogs. E. W. COON ET AL. (Oreg. Expt. Sta.). (*North Amer. Vet.*, 19 (1938), No. 9, pp. 57-59, fig. 1).—Report is made of the experimental treatment of so-called salmon poisoning, shown by Simms and his associates in Oregon (E. S. R., 65, p. 72) to be a fluke-borne infectious disease of dogs and other Canidae. A drop in temperature and return of the appetite followed within from 24 to 48 hr. after the first administration of sulfanilamide.

Bacteria of the *Listerella* group isolated from foxes. H. W. CROMWELL, E. E. SWEENEY, and T. C. CAMP (*Science*, 89 (1939), No. 2309, p. 293).—An organism found present in an affection of silver foxes which spread rapidly through the sheds of a fox fur farm in Illinois, with resultant high mortality, and was diagnosed as that of distemper is considered by the authors to belong to the *Listerella* group.

Treatment of fox distemper. G. L. ORT (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 522-525, figs. 5).—Experiments with several thousand animals in 1938 indicate that "the use of homologous anti-canine-distemper serum as a prophylactic agent against fox distemper is an economically sound measure."

[Report of work in avian pathology] (*Western Washington Sta. Rpt. 1938*, pp. 6, 35-37, 38, 44-46).—Reference is made to breeding experiments for disease resistance in chickens, by M. W. Miller, G. E. Bearse, and C. F. McClary; the use of milk flush for the control of cecal coccidiosis in chickens, a pullorum disease transmission experiment, and control of fowl pox through vaccination, all by C. E. Sawyer and C. M. Hamilton; gizzard erosions in chickens, by Sawyer, Hamilton, and L. G. Nicholson; wheat-germ oil for the treatment of fowl paralysis, by Sawyer and Nicholson; tapeworm transmission by garden slugs; transmission of leukemia; and control of coccidiosis by sanitation.

The disease factor in Illinois poultry mortality. R. GHAMAM. (Univ. Ill.). (*Vet. Med.*, 34 (1939), No. 3, pp. 170-172, figs. 4).

Brucellosis in fowls [trans. title], P. PAVLOV (*Rec. Méd. Vét.*, 114 (1938), No. 12, pp. 790-798).—Following a brief review of the literature, report is made of experiments conducted. Fowls inoculated were found less susceptible to *Brucella* than were mammals; the chicken was more susceptible than the pigeon. The rabbit appears to be much more susceptible to contact infection from the fowl than is the guinea pig. The organism was only present in eggs laid from 4 to 14 days after inoculation of the fowl with a *Brucella* culture. Agglutination and allergic tests are considered the most convenient and practical means of diagnosis.

The detection of carriers of fowl cholera, and its control, by means of a stained-antigen, rapid, whole-blood test. W. B. SHOOK and H. BUNYEA. (U. S. D. A.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 146-149).—Report is made of an outbreak of fowl cholera due to a carrier condition of several years' standing that was controlled by use of a stained-antigen, rapid, whole-blood agglutination test of the flock, followed by removal of the reactors. The stained-antigen test agreed with the tube agglutination test on 133 reactor birds, with negative controls. The stained antigen for the rapid, whole-blood test was made from 24-hr. agar growths of an autogenous blue type culture of *Pasteurella avicola* washed off with physiological saline containing 1 percent of formalin. The

* *Vet. Med.*, 32 (1937), Nos. 1, pp. 9-11, fig. 1; 2, pp. 76-82, figs. 11; 4, pp. 190-195, figs. 10; 5, pp. 234-242, figs. 15; 7, pp. 328-333, figs. 2; 9, pp. 414-417, figs. 4; 10, pp. 468-474; 12, pp. 570-574.

suspension was adjusted to a turbidity of 75×1 of the McFarland nephelometer scale and stained with 0.1 percent of crystal violet. The antigen was set aside for several days at room temperature before use.

The production of goiter in chickens, A. R. PATTON, H. S. WILGUS, JR., and G. S. HARSHFIELD. (Colo. Expt. Sta.). (*Science*, 89 (1939), No. 2303, p. 162).—The authors report having produced goiter in chickens with a ration containing 0.145 mg. per kilogram of iodine and have prevented it by the addition of 5 mg. per kilogram of iodine to the same ration.

An experimental attempt to produce lymphomatosis in chickens by injections with *Salmonella aertrycke* and lymphomatous nerve tissue, with observations on the blood pictures of the chickens, J. R. BEACH and N. M. TWISSELMANN. (Univ. Calif.). (*Poultry Sci.*, 18 (1939), No. 2, pp. 160-164, fig. 1).—The results of the experiment here reported failed to show that intravenous inoculation of young chickens with lymphomatous nerve tissue or the repeated oral administration of cultures of *S. aertrycke*, either alone or in combination, caused the development of lymphomatosis or produced a hemocytoblastosis or other changes in the blood pictures of the chickens. "Several types of abnormalities of blood pictures were found in 12 or 13 chickens with lymphomatosis. These, however, did not conform to any particular trend as to their nature nor with respect to the type of lymphomatosis with which the chickens were affected. Their appearance was nearly coincident with the development of paralytic symptoms in the case of neurolymphomatosis and shortly before death in the case of visceral lymphomatosis. They are regarded as a doubtful or valueless diagnostic aid."

Is fowl paralysis infectious? A. H. FRASER (*U. S. Egg and Poultry Mag.*, 45 (1939), No. 2, pp. 106-110, 122, 123, figs. 3).—Studies conducted at the Rowett Research Institute in Great Britain led to the conclusion that some infective factor which isolation tends to exclude, not worms and probably not coccidia, increases the incidence of fowl paralysis among poultry when other conditions are equalized. While the precise nature of the infective factor remains unknown, the results of 3 years' work on this disease indicate that fowl paralysis is infectious in nature.

Disease in turkeys due to *Prosthogonimus macrorchis*, R. W. MACY (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 537, 538, figs. 2).—Infestation experiments indicate that the turkey is poorly adjusted to the fluke *P. macrorchis* and that this fowl is an unnatural host. "Turkeys eagerly devour dragonflies, and flocks in the vicinity of lakes may easily become exposed to the infection. Therefore, during the period of maximum dragonfly emergence, May 20 to June 20, the birds should be kept some distance from the lakes."

Pullorum disease of turkeys: Studies on incidence and carriers, W. R. HINSHAW. (Univ. Calif.). (*Vet. Med.*, 32 (1937), No. 10, pp. 455, 456).—This account is based upon work conducted in California (*El. S. R.*, 78, p. 857).

Use of iodine for gapeworms in pheasants, J. P. DELAPLANE and H. O. STUART. (R. I. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 5, pp. 538, 539).—The treatment of some 20 gapeworm-infested pheasants in a large flock by instillation of a few drops of iodine vermicide in the trachea with a pipette or eyedropper is said to have relieved the symptoms of respiratory distress after a few days. No losses from gapeworm occurred in the flock following this treatment. In 2 gapeworm-infested pheasants showing paralytic symptoms that were treated by the authors, the symptoms of respiratory distress disappeared after 4 and 5 days. Autopsies of the 2 birds later failed to reveal any gapeworms, indicating the effectiveness of this form of treatment.

AGRICULTURAL ENGINEERING

Geology and ground-water resources of the Snake River Plain in south-eastern Idaho, H. T. STEARNS, L. CRANDALL, and W. G. STEWARD (*U. S. Geol. Survey, Water-Supply Paper 774 (1938), pp. IX+268, pls. 31, figs. 16*).—The chief purpose of the investigation here recorded was to obtain data regarding the source, movement, and disposal of the ground-water supply of the lava plains that occupy most of the region. By assembling and correlating numerous well records obtained in this and related investigations, tied together by a system of levels, the authors prepared a map of the region showing contours of the water table and the direction of movement of ground water in all parts of the region. This map largely indicates the source and disposal of the water. The total annual ground-water supply of the Snake River Plain is here estimated at 4,000,000 acre-ft., of which only a small part is now utilized for irrigation.

Deep well irrigation in the Oklahoma Panhandle, W. LANGHAM and W. N. McMILLEN (*[Oklahoma] Panhandle Sta., Panhandle Bul. 64 (1939), pp. 22, figs. 6*).—The water supply in the water-bearing strata is at present large but is the accumulation of years of seepage and has no other important sources. However, "though the depletion of this water supply is possible, it seems unlikely that irrigation will become extensive enough under the present conditions of high power rates, high pumping lift, and cheap crops to make the condition very probable." The quality was found to be good, but the mean depth of water-bearing strata in Cimarron County was somewhat more than 160 ft. as against an estimate of 100 ft. as the maximum economically practicable pumping lift. Cost is found to be the limiting factor. In an example given, "when the total annual pumpage was 273 acre-ft., fixed costs accounted for 41 percent of the total cost of an acre-foot of water, including the labor. Had this well been used to pump only 100 acre-ft., the total cost per acre-foot would have been \$9.53, of which approximately 66 percent would have been fixed charges. It is obvious that this item alone would make the pumping of water unprofitable regardless of the power rate. Though the item of fixed costs increases with the pumping lift, if maximum use of the plant is obtained, this item may not make cost of pumping prohibitive for pumping lifts well over 100 ft. Provided that operation costs can be minimized by an abnormally low rate of power, deep well irrigation may have some possibilities. Especially is this true in those favored areas along the creeks and rivers where the pumping lift may not be excessive. In these areas the development of natural gas resources affording a cheap source of power may even justify irrigation expansion, though it is obvious that dry-land farming must remain the basic agriculture in the entire region as a whole."

The relation of soil conditions to practicability of well irrigation, the status of four High Plains irrigation projects, general cost analyses, description of the well and pumping plant of the station, together with the cost of the well and equipment and the costs of operation, and cropping and water-handling notes are also discussed.

Sewage irrigation as practiced in the western States, W. A. HUTCHINS (*U. S. Dept. Agr., Tech. Bul. 675 (1939), pp. 60, figs. 14*).—This bulletin outlines the character of the problem in general terms and takes up in some detail sewage as a source of irrigation water supply, use of water, irrigable lands, crops, safeguards and regulations of public-health authorities, salts in sewage effluents, sewage water rights, and economic feasibility of sewage irrigation. An appendix lists areas in which irrigation with sewage taken directly from

outfalls or disposal plants is practiced, and areas using irrigation with sewage diverted from public stream channels.

It is noted that, in general, coarse-textured soils, loose in structure, have proved better suited to sewage irrigation than heavy soils of equivalent fertility, but many tracts irrigated with effluents consist of clay loams and clays. Difficulties with the heavy soils irrigated with effluents have arisen largely from lack of care and judgment in applying the water, rather than from the character of the water. The coarser-textured, lighter soils comprise two-thirds of the soil classes in the areas included in the study. Any change resulting from the use of sewage, so far as reported, was to the effect that the soil structure showed improvement. Crops irrigated with sewage are those commonly grown under irrigation in the locality. Reports generally indicate higher yields with sewage effluents than with other water applied under comparable physical conditions and with equal care.

Rural water supply and sewerage.—I, Excreta disposal and sewerage, E. W. STEEL and P. J. A. ZELER. (Tex. A. and M. Col.). (*Tex. Engin. Expt. Sta. Bul. 46* (1939), pp. 21, figs. 7).—This bulletin consists mainly of a non-technical discussion of the construction and operation of septic tank systems, including the function of the subsurface irrigation field, the operation of the sewage disposal system, the construction of the tank, the subsurface irrigation field, and cost estimates.

For preventing top flow straight through the tank, the authors recommend extra heavy cast-iron soil pipe tees at the inlet and outlet on the ground that tile tees are frequently broken and wooden baffles are likely to rot out.

Lumber requirements for nonfarm residential construction, F. J. HALLAUER (*U. S. Dept. Agr., Misc. Pub. 347* (1939), pp. V+39, figs. 18).—The author found evidence of a cyclical period of about 18 yr. in the construction of non-farm housing units and suggests a pattern for the cycle ending about 1950.

There has been a noticeable trend to brick and stucco over frame, but lumber exterior face makes up only some 10 percent of the total lumber in an all-wood house, and a partial substitution of other materials has not greatly reduced the lumber per unit. An analysis arrives at a prospective average annual requirement of 6.4 billion board feet of lumber for new residential construction and 1.4 billion board feet for repairs per annum. These estimates are based on the volume for a decade and cannot be applied to any one year. "An estimate year by year can be arrived at by applying the lumber per unit to the suggested construction cycle."

Bibliography on highway finance, compiled by L. W. HELVESTINE (*U. S. Dept. Agr., Bur. Pub. Roads, 1938*, pp. [4]+95).—In selecting the references the emphasis has been placed chiefly on the theory of highway finance. The principal objective of the list is to present a survey of literature on the various methods of financing employed today and the present trend of public practice. Articles in periodicals which present only the factual and statistical material compiled and published by the Bureau of Public Roads have been omitted from the list.

Public Roads, [April and May 1939] (*U. S. Dept. Agr., Pub. Roads, 20* (1939), Nos. 2, pp. [2]+21-44+[2], figs. 13; 3, pp. [2]+45-64+[2], figs. 15).—These numbers of this periodical contain data on the status of various highway projects receiving Federal funds as of March 31 and April 30, 1939. No. 2 also contains an article entitled *Experimental Bituminous-Treated Surfaces on Sand-Clay and Marl Bases*, by P. F. Critz and W. K. Beckham (pp. 21-43); and No. 3, articles entitled *Preliminary Results of Road-Use Studies*, by R. H. Paddock and R. P. Rodgers (pp. 45-54, 62, 63), and *A New Vibratory Machine*

for Determining the Compactibility of Aggregates, by J. T. Pauls and J. F. Goode (pp. 55-61).

Methods and machinery for harvesting soybeans, J. W. SJOEGREN (*Virginia Sta. Bul. 319* (1939), pp. 10, fig. 1).—The beater harvester, binder and mower, and combine harvesting methods were compared with reference to cost and efficiency.

The beater harvester, though adapted to small acreages and to harvesting soybeans planted between corn rows, caused losses of beans ranging from 20 percent under favorable conditions up to 60 per cent. The 3-yr. average loss for all tests and under the various conditions of the tests was 43 percent. As means for reducing the losses in this method of harvesting, the author suggests planting a variety with erect growth habits, ridging the rows slightly at the last cultivation, and allowing hogs to pick up the wasted seed after the harvester. The cost of harvesting soybeans with the beater harvester is about \$2.11 per acre, not including the value of the wasted seed. The binder and mower method of harvesting is used when the soybeans are planted broadcast or with a drill. The ordinary grain thresher can be adjusted to thresh soybeans without excessive cracking or splitting. The speed of the cylinder should be reduced, while the speed of the grain cleaner and the straw rack should be maintained at the regular speed recommended for grain. Special soybean attachments for adjusting grain separators are extensively used. Harvesting losses with the binder and thresher were 24.7 percent of the total yield, and farmers estimated losses of from 15 to 35 percent. The total cost was \$0.38 per acre, high compared with costs in other States. The combine is used extensively for soybeans planted in rows as well as drilled. The introduction of the small combine has increased its use for soybeans in Virginia. The average harvesting losses of the combine were 12.37 percent of the total yield. The combine was found to require the same type of adjustments as the grain thresher to thresh soybeans satisfactorily. Special equipment for threshing soybeans can be obtained for the combine. The cost of the small combine ranges from \$500 to \$900, depending on the width of cut and on the special equipment desired.

Artificial drying of farm crops in the United States: A selected bibliography, compiled by D. W. GRAF (*U. S. Dept. Agr., Bur. Agr. Engin., 1938, pp. [2]+46*).—This is a classified reference list containing abstracts of some of the papers noted. The references are grouped under the following headings: Description of machines, general, apparatus, corn, cotton, forage crops, grain, miscellaneous crops (hops, seeds, copra), rice, and sugar beets. An author index is included.

Portable field drier, R. M. HIXON and A. L. BAKKE. (Iowa Expt. Sta. and U. S. D. A.). (*Jour. Amer. Soc. Agron., 31* (1939), No. 3, pp. 268-270, figs. 2).—A partly dimensioned longitudinal section drawing, a photograph, and a brief outline of the method of construction describe a set-up 36 by 9.5 by 23 in., exclusive of the 6-v. battery which operates the blower. Air is blown into a hot water jacket compartment, baffled to prevent air channels, and is vented into four drying chambers above the heating chamber, each being baffled to force the hot air into the center of the chamber. The end compartment is water-jacketed to keep the temperature as high as possible. A steam outlet from this jacket leads to a condenser, made from an automobile heater. The condensate returns to the water bath through a copper pipe large enough to facilitate filling and to serve as blow-off. A rubber tube can be placed over the end of this vent and led to the ground to prevent wetting of the samples by escaping water. The water bath is heated with a portable gasoline camping stove.

The use of bituminous coal in the dehydration of alfalfa and other forage crops, E. R. KAISER (*Bituminous Coal Assoc. Inform. Bul. 3* (1939), pp. [1]+22, figs. 2).—As an advantage of artificial drying, as against sun curing, it is pointed out that artificially dried alfalfa may contain about seven times as much provitamin A as do field-cured plants. "By drying the hay at less than 180° F. while in an atmosphere consisting largely of nitrogen and products of combustion, oxidation is prevented, and the nutrients, including upward of 90 per cent of the carotene, are preserved."

"The marked saving in nutrients and the improved quality of dehydrated hay as the result of artificial drying are sufficient to warrant consideration of such drying for use at large dairy and hay farms for the production of whole hay."

As some of the advantages of bituminous coal as a fuel for the artificial drying of forage crops, the author notes its cheapness, as compared with other fuels on the basis of B. t. u. output, and the facts that bituminous coal, fired by stokers, is so completely burned by proper firing that the hay is not tainted, and that the rate of heat release from the coal-fired furnace can be controlled thermostatically as with oil or gas. The cost of heating and the saving with bituminous coal can be determined for a given plant by applying a method here given and illustrated. A suggested design of stoker furnace is shown. This may be modified to suit installations of various sizes.

Cereal nursery seeders, H. M. BEACHELL. (U. S. D. A. and Tex. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 3, pp. 265-268, figs. 7).—The author describes a seeder adjustable for uniform seeding with test weights varying from 35 to 52 lb. per bushel when sowing 90 lb. per acre in rows spaced 1 ft. apart. Provision is made for calibration and marking to permit quick and accurate setting.

The author also describes a spacing seeder which consists of small sheet metal cups $\frac{7}{8}$ by $\frac{3}{4}$ in. and $\frac{1}{2}$ in. deep attached to each link of a No. 25 cast drive chain. The cup was made from 28 gage sheet metal cut according to a dimensioned diagram. The speed of the chain to which the cups are attached is so regulated that a seed placed in each cup is dropped every 4 in. A single seed is dropped in each cup by hand, and any extra seeds dropped accidentally in a cup are removed with forceps. It was found that two men, one filling the cups and the other pushing the seeder, can sow approximately 450-rod rows in a 9-hr. day. With two men filling the cups and a third pushing the seeder, as many as 560 rows were seeded in 9 hr.

In addition to the construction shown in the diagram of the cup for the spacing seeder, some details of each of these seeders are shown in photographs.

An instantaneous steam generator for "sterilizing" milk utensils on the farm, K. G. BEACHELEY (*Jour. Dairy Sci.*, 22 (1939), No. 3, pp. 169-177, figs. 4).—The efficiency, cost of operation, and convenience of an instantaneous steam generator for the production of steam and hot water for washing and sterilizing dairy utensils were studied. The chief advantages of this equipment were compactness, speed of generating steam, small amount of labor to operate, economy of operation, and cleanliness, plus the fact that it was possible to combine chemical sterilizers with the steam in one operation and the utensils could be dried without removing them from the steam chest. The chief disadvantage was the large number of moving parts to wear and be greased, plus the fact that it did not provide for heating the milk house except by the use of radiators.

Artificial daylighting for color grading of agricultural products, D. NICKERSON. (U. S. D. A.). (*Jour. Opt. Soc. Amer.*, 29 (1939), No. 1, pp. 1-9, figs. 5).—Cotton grading was found, from a study of the demands of experienced classers, to require diffuse, nearly uniform illumination over a wide

working area; color matching that of slightly overcast north sky; and an intensity of from 60 to 80 footcandles in the horizontal plane in which the work is to be done. There was little advantage in an increase to more than 100 footcandles, and it was found best to avoid intensities higher than about 150 to 200 footcandles.

In a trial of an experimental set-up of 1,000-w. lamps set about 2 ft. apart from center to center, provided with "Daylite" filters, the background above the lamps painted with a zinc oxide paint to absorb infrared radiation as much as possible, and a diffusing skylight of glass ground on one side, it was found that with a filter-and-lamp combination approximating 6800° K. in color temperature, the cotton classers could work under it after becoming accustomed to it, but it was too yellowish to be a good substitute for slightly overcast north sky. Changing the Daylite filter from Macbeth 2ACL9, 5.5 mm. thick, to Macbeth BDK11 of the same thickness, and using lamps operating at 3000°, gave a color temperature of about 7400° and illumination "sufficiently like that from the overcast north sky which they [the Cotton Appeal Board] prefer to make the cotton look natural to them."

This result was obtained with lamps rated at 1,000-hr. life, 1,000-w. lamps in the outer rows, and 500-w. lamps in the center.

AGRICULTURAL ECONOMICS

[Proceedings of the twenty-ninth annual meeting of the American Farm Economic Association] (*Jour. Farm Econ.*, 21 (1939), No. 1, pp. 414, figs. 23).—Included are the following papers, with discussions, presented at the meeting held at Detroit, Mich., December 28-30, 1938 (U. S. R., 80, p. 432): Contributions of Agricultural Economics to Farming, by C. E. Ladd (pp. 1-7) (Cornell Univ.); Contribution of Agricultural Economics to the General Welfare, by H. R. Tolley (pp. 8-21) (U. S. D. A.); Effects of the AAA Program Upon Regional Specialization in Agriculture, by H. B. Rowe (pp. 31-43); Effect of the AAA on Farm Organization and Operation, by P. E. Johnston (pp. 46-54) (Univ. Ill.); Public Control of Land Use in Europe, by K. Brandt (pp. 57-71); Public Control of Land Use in the United States, by G. S. Wehrwein (pp. 74-85) (Univ. Wis.); How Fast Should Cooperatives Grow? by H. E. Babcock (pp. 89-95); Adapting Farm Management Research to New Opportunities, by S. E. Johnson (pp. 98-106) (U. S. D. A.); Soil Productivity Related to Farm Organization and Income, by G. W. Miller (pp. 107-113) (Ohio State Univ.); Type of Farming Modifications Needed in the Great Plains, by E. A. Starch (pp. 114-120) (Mont. State Col.); Federal Purchase and Administration of Submarginal Land in the Great Plains, by L. C. Gray (pp. 123-131), and Measuring Changes in the Demand for Farm Products, by F. L. Thomsen (pp. 132-142) (both U. S. D. A.); Consumers' Incomes and Demand for Certain Perishable Farm Products, by M. P. Rasmussen (pp. 145-154), and Long-Time Price Changes and Farm Operation, by S. W. Warren (pp. 156-164) (both Cornell Univ.); Technological Developments Affecting Farm Organization, by J. A. Hopkins, Jr. (pp. 165-177) (Iowa State Col.); Public Assistance to Low-Income Farmers in the North, by R. C. Smith (pp. 178-187), and Public Assistance to Low-Income Farmers of the South, by T. R. Reid (pp. 188-194) (both U. S. D. A.); Types of Livestock Markets and the Price Structure, by R. C. Ashby (pp. 195-214) (Univ. Ill.); Livestock Marketing Methods and Livestock Prices, by P. Richards (pp. 219-227) (U. S. D. A.); Legal Responsibilities of Farm Managers and Clients, by T. D. Morse (pp. 228-234); Economic Research Needed by Professional Farm Managers, by E. Walley

(pp. 235-237); Base Periods for Farm Price Studies, by O. C. Stine (pp. 238-242) (U. S. D. A.); The Case for the 1910-14 Base, by F. A. Pearson and K. R. Bennett (pp. 243-246) (Cornell Univ.); A Base in the 1920-29 Period for Farm Price Studies, by E. L. Butz (pp. 247-252) (Purdue Univ.); The Base Period for Parity Prices, by L. H. Bean and P. H. Bollinger (pp. 253-257) (U. S. D. A.); Land Values and Government Agricultural Policy, by C. H. Hammar (pp. 258-261) (Univ. Mo.); Monetary Policy in Relation to Land Values, by L. H. Bean (pp. 262-264) (U. S. D. A.); Land Values and Farm Credit Policy, by A. B. Lewis (pp. 265-267); Land Values and Commercial Bank Policy, by A. G. Brown (pp. 268-272); Land Rents and Land Values in Italy, by C. L. Stewart (pp. 273-275) (Univ. Ill.); Tax Reverted Lands in the Lake States, by E. J. Ellingson (pp. 276-279), and Land Use Problems in Minnesota, by R. M. Gilcreast (pp. 280-286) (both U. S. D. A.); Land Use Problems in Michigan, by F. P. Struhsaker (pp. 287-290); Ways and Reducing Costs of Distributing Milk in New York, by L. Spencer (pp. 291-298) (Cornell Univ.); Reducing Cost of Distributing Milk in California, by J. M. Tinley (pp. 299-306) (Univ. Calif.); Reducing Cost of Distributing Milk in Maine, by G. F. Dow (pp. 309-314) (Univ. Maine); "Education in Farm Finance" in Farm Management Extension Work, by C. R. Arnold (pp. 315-320); Economic Information in Farm Management Extension, by V. R. Wertz (pp. 321-325) (Ohio State Univ.); Farm Records and Accounts in Farm Management Extension Work, by H. A. Berg (pp. 326-331) (Mich. State Col.); Farm Management Facts in Building Area and State Programs, by J. H. McLeod (pp. 332-336) (Univ. Tenn.); Graphic Method in Price Analysis, by E. J. Working (pp. 337-345) (Univ. Ill.); Graphic Methods Used in Presenting Agricultural Economics Information, by R. G. Hainsworth (pp. 346-353) (U. S. D. A.); Developments Arising Out of Trial Census in 1938, by Z. R. Pettet (pp. 354, 355); Development of Partial and Sample Census Methods, by C. F. Sarle (pp. 356-364), Results of Four Methods of Sampling Individual Farms, by I. Holmes (pp. 365-374), and The Complementary and Competitive Character of Agriculture in Latin America and the United States, by L. A. Wheeler (pp. 375-379) (all U. S. D. A.); British Empire Trade Agreements in Relation to Trade in Farm Products Between Canada and the United States, by J. E. Lattimer (pp. 380-386); and Servicing Federal Land Bank Loans Through National Farm Loan Associations, by M. S. Kennedy, Jr. (pp. 388-396).

The reports of the officers and committees are also included.

[Papers presented before the British Agricultural Economics Society] (*Jour. Proc. Agr. Econ. Soc.*, 5 (1938), Nos. 2, pp. 103-170, figs. 3; 3, pp. 173-277).—These reports continue the series (E. S. R., 79, p. 120). No. 2 includes the following papers with discussions presented to the conference in London, December 7 and 8, 1937: The Practice of Price Stabilization, by A. N. Duckham (pp. 107-120); Some Aspects of Price Fixing Policies, by W. H. Jones (pp. 121-136); Experiences With Cost Accounts in Northern Ireland, by R. W. Hale (pp. 137-155); and The Recent Depression in Scottish Agriculture, by W. H. Senior (pp. 158-170); and No. 3 includes the following papers with discussions presented at the conference at Oxford, July 1-4, 1938: The Relation of Agricultural Education and Research to the Development of British Agriculture, by Earl de la Warr (presidential address) (pp. 190-211); The National Trust as Landlords, by D. M. Matheson (pp. 212-223); Agricultural Marketing With Special Reference to Potatoes, by W. Gavin (pp. 224-240); Agriculture and National Defense, by A. W. Ashby (pp. 241-258); and Manorial Traffic and Agricultural Trade in Medieval England, by R. Lennard (pp. 259-277).

Studies of economic conditions (*Nebraska Sta. Cir.* 60 (1939), pp. 75-78).—The station work is briefly reviewed from its inception.

Investigations in agricultural economics by the Ohio Station (*Ohio Sta. Bimo. Bul.* 197 (1939), pp. 34-36).—Included is an article by H. R. Moore on Tax Delinquent Rural Land Unsuitable for Agriculture in Southeastern Ohio, with table showing for 62 holdings of 40 acres or over in Hocking County and 276 holdings in Scioto County the land use, topography, and tax valuation per acre of land adapted, poorly adapted, and not adapted to agriculture. The table (*E. S. R.*, 80, p. 835) by J. I. Falconer of index numbers of production, prices, and income, is brought down through December 1938.

Development of legislation in Ohio that relates to agriculture, H. R. MOORE (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul.* 112 (1938), pp. [1]+II+72).—"The principal purpose in this publication is to trace only the development of legislation intended in some way to promote the interests of agriculture and the public welfare, through regulation and control under the police power of the State, through the authorization of various types of voluntary associations, and finally, through the creation of certain public institutions or publicly managed services administered by some department of the State or its subdivisions." The sections deal with legislation on the subjects of agricultural education, land use, cooperative associations, highways, taxation, landlord and tenant relationships, animals and fences, and regulatory legislation pertaining to agriculture.

Trends in public policy affecting agriculture as interpreted from legislative developments in Ohio, H. R. MOORE (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul.* 111 (1938), pp. [1]+18).—A summarization of the preceding bulletin.

The maintenance of agricultural production during depression: The explanations reviewed, J. K. GALBRAITH and J. D. BLACK (*Jour. Polit. Econ.*, 46 (1938), No. 3, pp. 305-323).—The following explanations that have been advanced are discussed: An attempt to offset falling prices by increased production, certain important differences in the competitive structure of industry and agriculture, certain physical or technological peculiarities of agricultural production which may inhibit response to price changes, the presence of greater or lesser degree of subsistence production in agriculture, and reduction in depressions of the prices of important cost factors.

The world agricultural situation in 1936-37 and 1937-38 (*Roma: Internat. Inst. Agr.*, 1939, pp. IV+275+[1], figs. 25).—The production and supply of the more important agricultural products, the general economic background of the agricultural situation, international economic relations, world trade in agricultural products, agricultural prices and incomes, and the agricultural policies in the different countries are described and discussed.

Foreign Agriculture, [April 1939] (*U. S. Dept. Agr., Foreign Agr. Serv., Foreign Agr.*, 3 (1939), No. 4, pp. 127-166, figs. 6).—Included are articles on The Hog Industry in Sweden, by H. B. Reed (pp. 129-140); British Cotton Textile Industry and Demand for Raw Cotton, by A. W. Palmer (pp. 141-154); and The German-Rumanian Economic Agreement (pp. 155-160); and notes on recent developments in foreign agricultural policy as follows: Cooperative societies of Mexico exempt from tax payments, Yugoslav Government to construct nationwide warehouse system, Japan adopts 10-yr. plan for agriculture in Taiwan, Germany to start ever-normal granary, Egyptian Government contemplates aid to cotton growers, and Poland to establish a hemp-production industry.

Changes in technology and labor requirements in crop production (*Philadelphia: Works Prog. Admin. [U. S.]*, 1938, Rpts. A-4, pp. XIII+134, figs. 11; A-5, pp. XVIII+181, figs. 42; A-6, pp. XVI+255, figs. 34; A-7, pp.

XVI+132, figs. 30; A-8, pp. XVI+163, figs. 34; A-9, pp. XV+114, figs. 37).—These reports continue the series (E. S. R., 79, pp. 694, 699).

A-4. *Potatoes*, H. E. Knowlton, R. B. Elwood, and E. G. McKibben.—This report discusses the importance of the potato crop, the changes in production practices and their effects on labor requirements, soil maintenance practices, and the development of improved varieties. Appendixes include tables showing acreage, yield, and production in the major production areas, the changes in production practices, potato-growing equipment, and labor used per acre, 1909-36; the number and acreage of farms surveyed in the study in 1936, and the distribution of such farms by amount of labor used; and abstract of data from secondary sources on labor requirements for potatoes.

A-5. *Corn*, L. K. Macy, L. E. Arnold, and E. G. McKibben.—The development in corn breeding, cultural methods, specialized corn equipment, and cultural practices and labor used in the corn, small grain, dairy, and cotton areas, and tractor adoption and labor requirements in corn production are discussed. Appendixes include tables showing the acreage, yield, and production of corn by areas, 1909-36; the estimated percentages of losses by diseases in the United States 1917-35; selected data on experimental studies in cultural practices; domestic sales of equipment 1899-1937; labor used 1909-19, 1929, and 1936 in producing corn by States; abstract of data from secondary sources on labor on corn; and notes on sizes of farms in the study.

A-6. *Trends in size and production of the aggregate farm enterprise, 1909-36*, R. G. Bressler, Jr., and J. A. Hopkins.—Two sets of index numbers are included. The first shows the changes in the size of the aggregate farm enterprise for the United States and each of the 11 major farming areas, and the second the changes of annual volume of physical production in each area. "Both of these indexes are weighted by the appropriate labor requirements per unit (acre, head of livestock, or unit volume of output) during the base period and thus represent measures of growth or decline commensurable with the indexes of the annual labor input into the agricultural industry, which will be presented in later reports. That is to say, the indexes of size of enterprise presented here could be described as measures of what agricultural employment would have been if the labor requirements per acre and per head of livestock had been throughout the entire period 1909-36 the same as during the base period of the indexes, 1924-29. Similarly, the indexes of production represent what employment would have been if the labor requirements per unit of product had not changed." No attempt has been made to develop explanations of the changes beyond pointing out a few of the more obvious ones. Tables, charts, and maps show for the United States and 11 areas the indexes of crop acreage, livestock numbers, and aggregate farm enterprise, 1909-36, and the production of principal crops and different kinds of livestock and livestock products.

Appendixes include tables showing the acreage, yield, and production, 1909-36, of different crops and different kinds of livestock, total and by areas, the enterprises included in the index of size of the aggregate farm enterprise, the weights used in computing the indexes of size of aggregate farm enterprise and production, and corrections in the indexes for crop abandonment, droughts, and A. A. A. programs.

A-7. *Cotton*, W. C. Holley and L. E. Arnold.—This report is limited to the trends in the amount of labor used in producing the cotton crop, and the effects of technological changes on these trends. The trends in acreage, yield, and production and in tenure groups of producers, the recent changes in operations and amounts of labor used, mechanization in cotton production, influence of improved

varieties of cotton, the development in cultural practices, and cotton diseases and insects are discussed. Appendixes include tables showing the acreage, yield, and production, 1909-36, by major cotton areas; percentages of farms reporting recognized varieties of cotton 1909-36; average staple length and percentages of cotton tenderable 1928-36; tons of fertilizer consumed 1909-35; average yearly amounts of labor used by States 1907-11, 1917-21, 1927-31, and 1933-36; and abstracts of data from secondary sources on labor on cotton.

A-8. *Trends in employment in agriculture 1909-36*, E. E. Shaw and J. A. Hopkins.—Included are tables, maps, and charts with discussion showing by years 1909-36 the average number of unpaid family workers and hired labor, and seasonal variations in each of the 12 agricultural districts into which the United States was divided. Appendixes describe the method used in estimating agricultural employment, the data used on number of farms, the Crop Reporting Board (U. S. D. A.) data on farm employment, the U. S. Census data on gainfully occupied persons in agriculture, index of man requirements for crops and livestock in California 1909-36 (E. S. R., 72, p. 401), part-time employment, indexes of size of enterprise handled and production per worker, 1909-36, and the monthly agricultural employment 1925-36.

A-9. *Tractors, trucks, and automobiles*, E. G. McKibben and R. A. Griffin.—This report describes the development and improvement of the tractor, farm production of tractor fuels, the adoption of farm tractors, trucks, and automobiles and effects on the size of farms, labor requirements, horse requirements, location of enterprises, etc. Appendixes show the chronological development of the tractor, statistics as to tractor sales, tractors on farms, displacement of farm animals and man labor, feeder requirements for work animals, etc.

Labor requirements for crop production in Ohio, R. H. BAKER (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 115 (1938), pp. IV+[1]+28, fig. 1*).—Charts or tables are included by which the man, horse, and tractor hours required to produce 1 acre of the principal crops in the western, north-eastern, and southeastern parts of the State with various combinations of methods of growing and harvesting can be determined. The charts are of a form similar to those on highway maps to show distances between points.

Land utilization in California: A list of references, compiled by A. POLI and P. J. WEBSTER (*U. S. Dept. Agr., Bur. Agr. Econ., 1938, pp. [1]+39*).—This is a mimeographed list of the more important studies in California and other States bordering on the Pacific Ocean.

Better land utilization for Ohio, J. H. SITTERLEY and J. I. FALCONER (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 108 (1938), pp. [1]+VIII+107, figs. 66*).—Part 1 (pp. 1-78) includes data on climate, topography, markets, present utilization of land, trend in the number, size, acreage, and crop acreages, type-of-farming areas, value of farm products, farm real estate values 1935, tenancy, tax delinquency, State contribution to schools, and open country population on relief November 1, 1934, and includes articles on Soils of Ohio, by G. W. Conrey (pp. 7-12); Primary Vegetation Areas in Ohio, by E. N. Transeau and H. C. Sampson (p. 19); and Population of Ohio, by G. H. Smith (pp. 21-32). Part 2 (pp. 79-83) discusses the objectives of a land use program. Part 3 (pp. 84-107) discusses desirable changes in land use in different areas, and describes the land use activities in the State.

Land use problems in central South Dakota, 1937 (*Brookings: S. Dak. State Planning Bd., 1939, pp. 27, [pls. 6], figs. [4]*).—Tables and maps are included showing the size of operating units, crop distribution, grass-crop ratios, livestock distribution, leasing arrangements, etc., in 27 counties.

An economic study of land utilization in southern Alberta, G. H. CRAIG and J. COKE (*Canada Dept. Agr. Pub. 610 (1938), pp. 79, figs. 16*).—Detailed

farm records were obtained by enumerators in the summer of 1935 from 493 farms in the area. The region and its people, land acquisition, farm abandonment, types of machinery used, amount of paid and unpaid labor, cash expenditures, etc., are discussed. Analysis is made of the relationship between size of farm, soil, and tenure, and the utilization of land, value of farm property, numbers of livestock, net returns, distribution and change in indebtedness of operators, and changes in net worth.

Physical and economic factors related to land use classification in southwest central Saskatchewan (*Canada Dept. Agr. Pub. 609 (1938), pp. 52, pl. 1, figs. 3*).—This is a preliminary report presenting economic information relating to the soil types in seven rural municipalities surveyed in 1935. The physical and climatological conditions, wheat yields, population, land tenure, land use, numbers of livestock, farm buildings, acquisition of land, vacant and abandoned farms, farm indebtedness, etc., are discussed.

Extending public control and management of forest land without purchase, C. H. HAMMAR (Mo. Expt. Sta.). (*Jour. Forestry, 37 (1939), No. 1, pp. 3-13*).—A proposed plan for combining public control and private ownership is outlined and discussed. The plan provides for continued private ownership under easement with control contracts granted to the Federal or State Governments.

Farm organization by soil type on the Eastern Highland Rim, C. E. ALLRED and A. C. ROBINSON (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 90 (1939), pp. [I]+III+34, figs. 10*).—This is a complementary study to that previously noted (E. S. R., 81, p. 126).

Factors determining types of farming, C. E. ALLRED and B. T. LANHAM, JR. (Coop. U. S. D. A. et al.). (*Tenn. Agr. Col., Agr. Econ. and Rural Sociol. Dept. Monog. 79 (1938), pp. [I]+II+37, fig. 1*).—This is a general discussion of the physical, economic, social, and biological factors determining types of farming.

Major economic trends in the dry edible bean industry, R. K. POND (*U. S. Dept. Agr., Agr. Adjust. Admin., Market Inform. Ser., 1938, GCM-6, pp. III+23, figs. 12*).—Charts and tables are included and discussed showing usually by years 1922-37 the production, prices, movements, foreign trade, freight rates, etc., for dry edible beans.

Costs and returns in apple production, Rouville County, Quebec, A. GOSSELIN (*Canada Dept. Agr. Pub. 624 (1938), pp. 15*).—Analysis is made of the financial returns for the crop years 1929-34, inclusive, and the cost of producing and marketing for the years 1932-34, inclusive. The data were obtained by farm surveys each year.

Financial results in fattening cattle, M. H. SAUNDERSON and A. ROTH, JR. (Mont. Expt. Sta.). (*Amer. Cattle Prod., 20 (1938), No. 7, pp. 1-8*).—Tables are included showing the necessary selling prices per 100 lb. for calves, yearling and 2-year-old steers, and cows, with prices of feed and livestock at different levels. The tables show the costs for animals, feed cost, labor, equipment, death loss, and interest rates.

Profitable dairy management, K. T. WRIGHT and A. C. BALTZER (*Michigan Sta. Spec. Bul. 297 (1939), pp. 57, figs. 23*).—Complete cost records were obtained from 64 to 148 (total 499) dairy herds throughout the State for the years 1932-36, inclusive. The costs and returns per cow and unit of production, and the factors affecting such costs and returns are analyzed.

The farms averaged 159 acres, with 80 percent of the land in feed crops, 13 cows and accompanying young stock, 9 ewes, 118 hens, and slightly less than 1 sow. The average feed consumption per cow per year was approximately 1 ton of concentrates, 1.5 tons of hay, 2.7 tons of silage and roughage, and 166

days pasture. The average labor requirement per cow per year was 154 hr., and the average cost \$140, of which \$57 was for feed, \$29 for labor, \$14 for management, \$9 for use of buildings and equipment, and \$31 for other items. The average income from herds producing an average of 389 lb. of butterfat per cow was approximately \$134. The farm cost per 100 lb. of milk was \$1.79. The annual costs and net returns per cow and the labor and management returns per hour increased from approximately \$107, \$87, and 11 ct., respectively, for the herds producing under 250 lb. of butterfat per cow, to approximately \$163, \$165, and 31 ct., respectively, for the herds with 400 lb. or over of butterfat per cow. The cost per pound of butterfat was 50 ct. and 38 ct., respectively. Feed cost per pound of butterfat was 60 percent higher in the high-feed-cost herds and 23 percent higher in medium-cost herds than in the low-cost herds. The most efficient dairyman averaged 32 hr. labor per 100 lb. of butterfat and the least efficient 64 hr. A total of 189 hr. of labor per cow was spent on herds averaging 6 cows as compared with 137 hr. on those averaging 26 cows.

Cost of milking averaged 29 ct. per 100 lb. of milk with hand-milking and 30 ct. with machines in herds of less than 10 cows, and 28 ct. and 22 ct., respectively, in herds of over 10 cows. The net returns per cow per year averaged 20 ct. where milk was sold as market milk, —\$16.04 where sold as condensery milk, and —\$20.16 where cream was sold to creameries. Labor and management returns per hour were 28 ct. in the eastern, 29 ct. in the southwestern, and 20 ct. in the central and northern sections of the State. The average total costs per pound of butterfat and per hundredweight of milk were Holsteins 42 ct. and \$1.50, Guernseys 41 ct. and \$1.95, and Jerseys 40 ct. and \$2.07. The average net returns per cow per year and total costs per pound of butterfat were —\$4.53 and 40 ct. in herds with less than 25 percent purebred cows, —\$1.11 and 40 ct. where 25 to 74 percent of the cows were purebred, and —\$11.80 and 43 ct. where over 75 percent were purebred. The total cost per pound of butterfat was 32 ct. in the low-cost one-fifth of the herds and 53 ct. in the high-cost one-fifth. The net return varied from —\$1.53 in February to +\$1.39 in June, and the return per hour for labor and management from 17 or 18 ct. in October to February, inclusive, to 41 ct. in June.

Public regulation of milk marketing in California, J. M. TINLEY (*Berkeley: Univ. Calif. Press, 1938, pp. XI+213*).—The economic background of the present milk control legislation of California is described, the salient features of present legislation are discussed, and analysis is made of the procedures and methods adopted to determine the basis for resale prices of fluid milk.

Milk industry of the State of New York with particular reference to the New York Metropolitan Area, J. J. BENNETT, JR. (*New York: Case Press, Inc., 1938, pp. [2]+129, [figs. 4]*).—This is a report of the Attorney General of New York to the Governor and Legislature. It discusses among other things the metropolitan market in fluid milk as a field for monopoly, production, use, and distribution of milk, method of sale, the bargaining cooperatives, the Rogers-Allen Law of 1937, and the bargaining agencies under this law, the cost of handling, pasteurizing, and distributing milk, prices, profits, etc.

Relative prices to producers under selected types of milk pools, T. G. STUTTS, W. C. WELDEN, E. W. GAUMNITZ, O. M. REED, and H. L. FOREST (*Farm Credit Admin. [U. S.], Coop. Div., Bul. 25 (1938), pp. IV+127, figs. 9*).—This study, made in 1937 in cooperation with the U. S. D. A. Agricultural Adjustment Administration, has for its objectives "to present a general treatment of the questions involved in pooling milk-sales returns; to describe milk-marketing conditions in Boston with special reference to variations in the milk supply which have been or may be of significance in pooling operations; to measure some of the effects of such variations on the annual prices received by various groups of

producers, when a selected number of the more common methods of pooling are used to distribute sales returns; and to indicate in a broad way the possible nature of further studies of this subject." The analytical parts deal entirely with the conditions in the milkshed and marketing area of Boston, Mass. The first section is mainly a description of the supply area for the Boston milk market, and the second a description of the development of milk pools and a discussion of the history of cooperative associations of producers, class prices of milk, and pools of sales returns in the Boston market. The third section is a rather broad and technical treatment of the factors involved in pooling sales returns, and the fourth a statistical analysis of the effect of different methods of pooling on the pattern of prices to producers. The statistical analyses are based chiefly on information collected in the administration of Federal programs regulating the handling of milk in the Boston market. Appendixes include a description of the method used in calculating the milk-pool prices and the basic statistical data used in the study.

The surplus problem in the northeastern milksheds, L. SPENCER. (Coop. Cornell Univ.). (*Farm Credit Admin.* [U. S.], *Coop. Div., Bul. 24* (1938), pp. IV+88, figs. 21).—This study covers the New England States, New York, New Jersey, Pennsylvania, Delaware, Maryland, and the District of Columbia. Special attention is given the New York milkshed, but the Pittsburgh, Pa., market is not included. The data were obtained from the Federal and State departments of agriculture, the principal cooperatives, milk dealers, and cream buyers in each market. Part 1 on the utilization of milk discusses the demand and supply situation, production and disposal of milk by farmers, utilization of milk, and sharing the surplus milk in the New York milkshed. Part 2 on western cream deals with the development of the trade, sources, quality requirements, shipments, etc., and the operations, methods of selling, costs of making and shipping cream, net returns, etc., of western cream plants.

Problems in the basic-surplus plan in the Philadelphia milk shed, J. ANDER (Diss. Univ. Pa., Philadelphia, 1937, pp. 166, [figs. 2]).—This dissertation discusses the factors determining the prices of milk, milk price plans, the development and operation of the Philadelphia plan, and minority objections to this plan.

An economic study of the consumption of milk and cream in certain urban and rural districts of Canada, W. C. HOPPER and G. P. BOUCHER (*Canada Dept. Agr. Pub. 608* (1938), pp. 42, figs. 14).—Surveys were made in the cities of Oshawa, Ont., Quebec, and Calgary, Alta., a village in each province, and five farm areas, including three cheese-producing and two non-cheese-producing areas in the provinces of Ontario and Quebec. Analysis is made of the consumption of fluid milk, cream, and manufactured milk, and the relations of locality, income, size of family, and nationality to consumption.

Post-war developments in the marketing of butter, W. H. NICHOLLS (*Iowa Sta. Res. Bul. 250* (1939), pp. 321-384, figs. 5).—This bulletin deals chiefly with the increased importance of large business units in the marketing of butter, special attention being given to changes in channels of distribution, concentration in the butter industry, and supplementary and complementary relationships involved in the recent increased diversification of dairy products distributed.

Butter marketing 1918-20, the developments 1921-27, the merger and diversification 1928-30, and the changes during the depression 1931-37 are described and discussed, and an economic appraisal made. The most important marketing channels 1918-20 were wholesaler-jobber, and a manufacturer-direct-to-retailer movement. For the first time the volume of farm-made butter for the country as a whole fell below that of creamery butter. To an important extent

butter reached the consumer unpackaged, and Federal grading existed only in the central markets. The period 1921-27 was marked by an increased emphasis on high quality butter, the rapid increase in various types of large scale direct-distributing agencies, and a reduction in the number of wholesalers. The most important development 1928-30 was the rise of large dairy corporations and their marked trend toward production diversification and territorial expansion. The period 1931-37, in spite of the continued increase in direct marketing, was a period of retrenchment and consolidation of past gains, and the author states "finally, in recent years the accuracy of the present butter-pricing mechanism has been questioned more than ever before. The development of direct buying and direct selling have so reduced the volume of wholesale trading that—combined with the very old problem of an almost universal 'premium' over the quotation—a drastic change in the basis of quotations or price-reporting policy will probably have to result if the volume of wholesale trading on the central markets continues to fall."

The livestock auction in Ohio, with a supplement on livestock dealer registrations, G. F. HENNING and E. B. POLING (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 110* (1938), pp. [2]+19, figs. 1).—Using data on questionnaires returned by 207 farmers during each of the years 1934, 1935, and 1936, inclusive, the use made of livestock auctions, percentage of livestock sold and purchased through such auctions, the prices received, the advantages and disadvantages of auctions, and the satisfaction or dissatisfaction of the farmers with them are discussed.

The changing relative importance of the central livestock market, E. A. DUDDY and D. A. REVZAN (*Jour. Business Univ. Chicago, Studies Business Admin.*, 8 (1938), No. 4, pp. VII+122+[43], figs. 13).—The organization and functions, the forces contributing to the origin and growth, the changes in the importance of central livestock markets, the reasons for the growth of decentralized marketing, and the relation of the price spread to changes in marketing method are described and discussed.

Marketing practices in producers' local cotton markets, J. W. WRIGHT (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1938, pp. [2]+92, figs. 2).—This preliminary report, based on data collected by the survey method in 101 markets throughout the Cotton Belt at the end of the 1935-36 marketing season, describes the problems of marketing cotton, the marketing practices of growers and first buyers, and makes an appraisal of the possibility of solving the present problems by adjustments in marketing procedures.

Trading in commodity futures (*U. S. Dept. Agr., Commod. Arch. Admin.*, [1939], CEA-14, pp. [5]+40, figs. 13).—Tables, charts, and maps are included and discussed showing the agricultural commodities having futures markets, the location of such markets, average volume of futures trading in each commodity, open contracts in various wheat futures on the Chicago Board of Trade semimonthly for the year beginning July 1, 1936, number of offices of registered futures commission concerns by States February 1, 1938, occupations of futures traders in corn and wheat on the Chicago Board of Trade September 29, 1934, and the percentages of the futures wheat contracts on long and short contracts held by speculators and hedgers, character of open wheat contracts June 14-July 31, 1933, on the Chicago Board of Trade, relation between futures trading and annual production of wheat and cotton and total bank deposits, cash or spot prices and futures prices, volume of futures contracts on the Chicago Board of Trade settled by delivery, etc. The principal marketing functions of the organized commodity exchanges and the Commodity Exchange Commission are described.

Supplement [Nos. 3 and 4] to digest of decisions of the Secretary of Agriculture under the Perishable Agricultural Commodities Act, W. L. EVANS (*U. S. Dept. Agr., Bur. Agr. Econ., 1938, pp. [1]+39; 1939, pp. [1]+93*).—No. 3 supplements the digest (E. S. R., 78, p. 557) as revised by Supplement No. 2 (E. S. R., 79, p. 123). No. 4 supersedes No. 3 and includes all decision numbers and statements of rulings under the act since February 1, 1938.

Terminal fruit auctions as marketing agencies for farmers' cooperatives, K. B. GARDNER (*Farm Credit Admin. [U. S.], Coop. Div., Bul. 29 (1938), pp. VII+90, figs. 9*).—This study was made to develop information for the assistance of members and managements of cooperatives in appraising the auction as a marketing agency. It is limited to some of the more important problems that could be dealt with from a statistical standpoint, dealing especially with the relationship between auction and private sale prices, the extent to which sales through terminal auctions meet the requirements of the trade in certain markets, the operations of representative auction companies as to classes of purchasers, relative importance of each class, number of commodities purchased by individual buyers, frequency of purchases, auction company ownership, relative importance of receivers, attitude of the buying trade to the auction method of sale, etc., and the factors bearing on whether large-scale purchasers can be adequately served by present auction sale methods. Most of the data were secured in the offices of 12 terminal auction companies in Baltimore, Boston, Chicago, Cincinnati, Cleveland, Detroit, New York, Philadelphia, Pittsburgh, and St. Louis, with some data as to volume of business from companies operating in Minneapolis, St. Paul, and New Orleans. The data are analyzed and discussed in sections on auction functions and services, price considerations, operating aspects, attitude of the buying trade, and large-scale purchasing at auction and at private sale.

Income parity for agriculture.—I, Farm income. III, Prices paid by farmers for commodities and services (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Adjust. Admin., and Bur. Home Econ., 1938, pt. 1, sects. 1, pp. [2]+II+59, [fig. 1]; 2, pp. [2]+II+41, [figs. 3]; 3, pp. [2]+II+10+[19], figs. 3; pt. 3, sects. 1, pp. [2]+II+27+[2], fig. 1; 2, pp. [2]+II+31+2; 3, pp. [2]+13+[2]; 1939, pt. 1, sects. 5, pp. [2]+II+92, figs. 2; 6, pp. [2]+II+61, figs. 6*).—These are the first of a series of preliminary reports presenting the findings as to farm income, expenses of agricultural production, prices paid by farmers for commodities and services, and income to farmers from nonfarm sources.

Part 1 includes the following sections: (1) Income from cotton and cottonseed, calendar years 1910-37, consisting of tables and charts showing for the United States and by States the sales, average price, and cash income from cotton lint and cottonseed, and the quantity and value of cotton and cottonseed in the possession of farmers January 1. (2) Income from tobacco, calendar years 1909-37, includes similar data for tobacco. (3) Income from hogs, calendar years 1909-37, shows for the United States cash and gross farm income, 1909-37; sales, prices, and income, relation of farm income from hogs and income of industrial workers, 1920-37, and for the United States and States the cash and gross incomes from hogs, pork, and lard; value of hogs slaughtered at home, number and value of hogs on farms, and the cost of hogs shipped in for feeding and breeding. (4) Income from wheat, calendar years 1910-37, shows for the United States the value of sales and home-consumed wheat; sales, prices, and cash income; and for the United States and by States sales, average price per bushel, cash income, and quantity and value of wheat in possession of farmers January 1. (5) Income from sheep and lambs, wool, and mohair, calendar years 1909-38, shows for the United States, 1909-38,

the value of sheep and lambs sold and consumed at home; sales, prices, and income; relation of incomes from sheep and lambs and that of industrial workers, 1920-38; sales, prices, and income from wool and mohair, and for the United States and by States the cash income from sheep, lambs, and wool; value of sheep and lambs slaughtered; cost of sheep shipped in for breeding and feeding; number and value of sheep on farms; sales, farm prices, and cash income for wool; and income from mohair.

Part 3 includes the following sections: (1) Medical service rates to farmers, 1910-14, 1924-29, 1932, and 1935-36, consisting of charts and tables showing data by regions of the United States as to hospitals, changes in doctors' fees 1910-14, 1924-29, 1932, and 1935-36, average expenditures per farm for medical services of different kinds 1935-36, and average physicians', dentists', oculists', optometrists', hospitals', and nurses' fees and charges to farmers. (2) Rates for electricity for farm home and farm power, 1910-14, 1920, 1924-36, shows by regions of the United States the index numbers of weighted average monthly bills for electricity for residences and for power, number of farms served by central electric stations for residences and power, and for selected States in each region the monthly bills for specified quantities of electricity. (3) Telephone rates to farmers in the United States, 1910-14, 1924-29, 1932, and 1935-36, consisting of tables and charts showing by regions of the United States the index of monthly charges to farmers for telephone service, the number of telephones on farms (by States), percentages of rural and urban homes with telephones, number of telephones by States on farms by types of companies 1930, etc.

Factors affecting farm prices, C. E. ALLEED and P. T. SANT (*Tenn. Agr. Col., Agr. Econ. and Rural Sociol. Dept. Monog. 80 (1938), pp. I+IV+36, figs. 11*).—The factors affecting prices in general and those affecting specific groups of agricultural commodities—cotton, grain, dairy products, hogs, poultry and eggs, beef cattle, sheep and lambs, and wool—as they relate to Tennessee conditions are discussed.

Price spreads between the farmer and the consumer, R. O. BREN, JR., and F. V. WAUGH (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. [2]+73, figs. 5; 1939, pp. [1]+31*).—The first report covers the period 1913-35. Tables show by years by product or groups of products for 58 food products used by workmen's families the retail value, equivalent farm value, actual margin, and farm value as percentage of retail value. Other tables and charts present data as to workmen's expenditures for food, the annual consumption of each of the 58 foods, the relation of retail and farm value of the food consumed by a typical workman's family, relation of margins of the 58 foods consumed and hourly earnings of wage earners, and the relation of margins to supply for selected foods. The methods of calculating the farm and retail values and spreads are discussed.

The second report brings the data down to December 1938.

Relation of cotton production to consumption by areas, Tennessee, C. E. ALLEED, B. D. RASKOFF, P. B. BOYER, and G. H. HATFIELD. (*Coop. U. S. D. A., Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 58 (1937), pp. [1]+III+27, figs. 6*).—Grade and staple length of cotton produced and consumed in different sections of the State and practices of mills in making purchases are described. The State consumes only 36 percent of the cotton it produces, and about 60 percent of its consumption is purchased out of the State.

Consumption of citrus fruits and related products in Baltimore and St. Louis, G. W. HERVEY (*U. S. Dept. Agr., Agr. Adjust. Admin., Consum. Counsel Ser., Pub. 6 (1938), pp. IV+69, figs. 7*).—Using a schedule having 20 items, some with detailed subitems, data were obtained in the spring of 1936

for approximately 1,000 households each in Baltimore and St. Louis on consumer attitudes, preferences, purchasing habits, and other factors determining the use of fresh oranges and grapefruit, canned grapefruit, canned tomato, grapefruit, pineapple, prune, and orange juices, and dairy orange beverage. The frequency of use, quantities consumed, manner of use, relation of income to consumption, preference for brands, source of purchases, including relation of nationality, income, and price to source, etc., are discussed.

The frozen food industry: Selected references January 1937 to March 1939, compiled by H. E. HENNEBRUND (*U. S. Dept. Agr., Bur. Agr. Econ., Econ. Libr. List 2 (1939), pp. 14*).—This is a mimeographed list.

Report on systems of agricultural credit and insurance, L. TARDY (*Gèneve (Geneva): League of Nations, Econ. and Financ., 1938, pp. VIII+116*).—This is a report to the League of Nations on an inquiry made with special reference to the countries of central and eastern Europe. It summarizes general conclusions based on the inquiry and the author's experience with agricultural credit practices in France and other countries on the value of credit in agriculture, development of agricultural mutual aid and cooperative organizations, need for credit suited to special conditions of agricultural production, methods of providing farmers with credit, resources utilized by agricultural credit institutions for making loans, security required for the repayment of loans, insurance against agricultural risks, farmers' indebtedness and the remedies adopted, and the organization of agricultural credit on an international basis. Recommendations are made regarding agricultural credit and agricultural insurance systems. An appendix includes a brief survey of the various countries of the world grouped on the basis of whether the organization for agricultural credit is largely centralized with direct State intervention, mixed with coexistent State organs and cooperative institutions, or consists of cooperatives receiving State encouragement and independent organizations, mostly cooperatives, not receiving State encouragement.

Agricultural long-term credit facilities in Great Britain, D. WITNEY (*Jour. Roy. Agr. Soc. England, 99 (1938), pp. 1-14*).—The progress and achievements under the Agricultural Credits Act of 1928, applicable to England and Wales, and the Agricultural Credits (Scotland) Act of 1929 are discussed. The financial structure of the Agricultural Mortgage Corporation, Ltd., and Scottish Agricultural Securities Corporation, Ltd., the methods of making loans, and the utilization of long-term credit facilities are discussed and general conclusions drawn.

Financial study of the joint stock land banks: A chapter in farm mortgage banking, C. H. SCHWARTZ, JR. (*Takoma Park, Md.: Wash. Col. Press, 1938, pp. XIV+210, [figs.] 3*).—The organization, development, and liquidation of the banks are discussed in chapters on economic and legislative background, organization of the banks, loaning activity, loan collection experience, foreclosures and real estate, financing the loaning operations, financial operations, land bank finance, receiverships, and liquidation. The author draws "certain conclusions from the experiences of these banks which may be valuable both from the point of view of banking history in the United States and that of the future of mortgage banking in general." Appendixes include a comparative synopsis of provisions of the Federal Farm Loan Act of July 17, 1916, respecting Federal and joint stock land banks, and tables showing by years 1917-37 the number of banks chartered, merged, liquidated, placed in receivership and in operation at the end of the year, and the name, date chartered, charter territory, and status of charter of the banks.

Semi-annual index of the farm real estate values in Ohio January 1 to June 30, 1938. H. R. MOORE (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 113* (1938), pp. 5+1, fig. 1).—This bulletin continues the series (E. S. R., 80, p. 259).

Report and recommendations of the Farm Tenancy Committee (*Des Moines: Iowa State Planning Bd., 1938, pp. 63, figs. 4*).—This committee of 45 members, appointed by the Governor of Iowa, consisted of farm-owner operators, tenants, landlords, "institutional" farm owners such as insurance companies, legislators, and representatives of farm organizations, farm journals, and newspapers. Hearings in each county of the State and one State-wide hearing were held. Data were accumulated in the form of hearing reports, briefs, letters, and nearly 4,000 filled-out questionnaires. The present tenancy problem and Federal and State policies are discussed, and specific recommendations made as to measures to encourage farm-home ownership and to improve landlord-tenant relationships.

Farm leases being used in Tennessee. C. E. ALLEN, H. J. BONSER, and D. K. LAW (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 91* (1939), pp. 11+11+73, fig. 1).—Included are lease forms in use in the State under varying conditions.

American cooperation, 1938 (*Washington, D. C.: Amer. Inst. Coop., 1938, pp. XIV+734, figs. [8]*).—This is a collection of 107 papers presented at the fourteenth summer session of the American Institute of Cooperation held at Pullman, Wash., and Moscow, Idaho, July 11-15, 1938. The papers deal with the economic and social foundations of cooperation, the developments in current problems in cooperation, Government programs and the cooperative pattern, the financial structure of cooperation, cooperative marketing of poultry and eggs, fluid milk, manufactured dairy products, wheat, tree fruits, small fruits and vegetables, potatoes, livestock and wool, and nuts, and cooperative purchasing of farm supplies. "Subjects considered ranged from practical problems confronting the cooperating farmer and his associations to a presentation of the latest trends in economic and social thought as they affect agriculture in general and the development and well-being of farm cooperation in particular."

A statistical handbook of farmers' cooperatives (*Farm Credit Admin. [U. S.], Coop. Div., Bul. 26* (1938), pp. XII+334, figs. 19).—This handbook deals with farmers' cooperative marketing and purchasing associations, mutual irrigation companies, mutual fire insurance companies, and some other types of cooperation, including grazing associations, rural electrification associations, and soil conservation associations. Such organizations as breeders, cow testing, fairs, contact locals, "educational" (4-H clubs, Future Farmers of America, horticultural societies, etc.), "general farm organizations" (grange, farm bureaus, farmers' unions, etc.), and farmers' mutual telephone companies are not included. The data were collected in cooperation with 32 State agricultural colleges, the college of agriculture of the University of Puerto Rico, and the Colorado director of markets. The tables and charts show for marketing and purchasing associations by State and commodity types data as to number, date of organization, legal status, membership, volume of business, assets, liabilities, borrowed capital, patronage dividends, number of and business with members and nonmember patrons, basis of voting, farmer control, etc.; for mutual irrigation companies, location, legal status, members, patronage, assets, liabilities, indebtedness, etc.; and for mutual fire insurance companies, location, insurance in force, types of business, terms of policies, assessments, borrowings, etc.

Pages 1-19 summarizes the more important findings.

Co-ops in agriculture, F. M. HYER (*Farm Credit Admin.* [U. S.], *Coop. Div., Cir. C-111* [1939], pp. 22, fig. 1).—A popular bulletin giving information based on the preceding bulletin.

Cooperatives in South Dakota, L. M. BROWN and R. J. PENN (*South Dakota Sta. Bul.* 328 (1939), pp. 31, figs. 7).—The data, most of which are for the fiscal year 1935-36, were obtained from 354 associations, including elevators, oil stations, creameries, stores, etc. The extent of cooperation in the State, the time and purpose, legal aspects, organization and structure, financing, and results of cooperative associations are discussed.

Cooperative fluid-milk associations in Iowa, P. E. QUINTUS and T. G. STIRTS. (Coop. Iowa Expt. Sta.). (*Farm Credit Admin.* [U. S.], *Coop. Div., Cir. C-105* (1937), pp. III+72, figs. 7).—Information was obtained in 1935 and 1936 by surveys of the cooperative fluid milk associations of the State, and from interviews with leaders in dairying. The special problems of milk marketing in the State, the early cooperative efforts, the present organization, and corporate and cooperative features of the associations are discussed. The operating practices, management and accounting, sales plans, methods of making payments to producers, membership policies, the transportation of milk and cream, etc., are discussed.

Patronage problems of Mid-West Producers' Creameries, Inc., G. C. LAUGHLIN and T. G. STIRTS (*Farm Credit Admin.* [U. S.], *Coop. Div. Cir. C-106* (1938), pp. IV+59, figs. 9).—The Mid-West Producers' Creameries, Inc., established in 1932, is primarily a service organization for 20 member creameries in Michigan, Indiana, Tennessee, and Illinois. The organization, financial structure and condition, and the services rendered the member associations by the Mid-West Producers' Creameries, Inc.; membership policies, financing, procurement methods, and costs of the member associations; the factors affecting sales returns; operating efficiency; prices paid for butterfat; creamery operating margins; and price systems are discussed.

Financial operations of Ohio farmer owned elevators during the fiscal year 1937-38, B. A. WALLACE (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul.* 116 (1938), pp. [I]+20).—This bulletin continues the series (E. S. R., 78, p. 870).

Cooperative purchasing through the Illinois Farm Supply Company and its member county companies, J. H. LISTER (*Farm Credit Admin.* [U. S.], *Coop. Div., Bul.* 27 (1938), pp. VI+173, figs. 31).—The membership of the Illinois Farm Supply Company, one of the 13 units of the Illinois Agricultural Association, in 1936 consisted of 62 county service companies (farmer-owned cooperative oil associations), 3 cooperative marketing associations, and a State-wide grain marketing association. Part 1 discusses the growth and control of the Illinois Farm Supply Company, its services to member companies, and its operating and financial status. Part 2 discusses the growth and control, the method of operation, the operating efficiency, and financial condition of the county companies and their relation to the Illinois Farm Supply Company. Suggestions are made for improving the system and its operation. The data which cover the operating years 1926-36 were obtained by interviews with the officials of the companies, questionnaires, annual reports, audits, and other operating reports, etc. Appendixes include articles on incorporation, bylaws, and membership agreements of different classes of members, a standard form of articles of incorporation for county service companies, accounting forms, and tables of basic statistical data used in the study.

Farmers' purchasing associations in Wisconsin, R. K. FROKER and J. G. KNAPP. (Coop. Wis. Expt. Sta.). (*Farm Credit Admin.* [U. S.], *Coop. Div., Bul.* 20 (1937), pp. IV+118, figs. 9).—Data were gathered in 1935 by visits to

practically all the local and wholesale farmers' purchasing associations in the State. The development, legal basis, types, location, and operating records of cooperative purchasing associations in the State are described. The general organization, operating methods, financial and operating condition, and the comparative standards for measuring operating efficiency of different types of local cooperative associations, and the structure, methods, and operations of large-scale purchasing associations are analyzed and discussed.

Farmers' mutual windstorm-insurance companies, G. A. BUBOLZ (*Farm Credit Admin.* [U. S.], *Coop. Div., Bul. 21* (1938), pp. IV+39, figs. 4).—The development, costs of insurance, accomplishments, etc., of farmers' mutual windstorm-insurance companies are described and discussed. An analysis is made of the articles of incorporation, bylaws, contracts, etc., of over 50 companies. The data were obtained through questionnaires, letters, and interviews, and from the reports of State insurance departments.

Forest fire insurance in the northeastern States, H. B. SHEPARD (*U. S. Dept. Agr., Tech. Bul. 651* (1939), pp. [2]+II+46, figs. 6).—This bulletin follows the same lines as that for the Pacific Coast States (*U. S. R.*, 77, p. 52). The contributive and causative forest fire hazards, and the construction of the rating schedules for different types of forest regions in the northeastern States are discussed. Recommended insurance forms for the area are included.

Crops and Markets, [April 1939] (*U. S. Dept. Agr., Crops and Markets*, 16 (1939), No. 4, pp. 69-88, figs. 2).—Included are crop and market reports of the usual types.

The estimated gross cash income from the sale of agricultural products from Ohio farms by counties—1936 and 1937, P. P. WALLBARENSTEIN and J. I. FALCONER (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 114* (1938), pp. [1]+19).—This bulletin continues the series (*U. S. R.*, 76, p. 260).

World production in meat, A. BEIZI (*Internatl. Inst. Agr. [Roma], Studies Princ. Agr. Prod. World Market*, No. 3 (1938), pp. XI+319, pls. 8, figs. 15).—This volume supplements that on International Trade in Meat (*U. S. R.*, 78, p. 877). Part 1 (pp. 1-19) deals with the total number and distribution of livestock throughout the world, and the density of livestock per thousand population. Part 2 (pp. 21-223) covers the evolution of the bases of meat production, the development in livestock numbers, and the trend of slaughtering and production. Part 3 (pp. 225-295) deals with tendencies in the development of production and trends in the utilization of livestock. Statistical tables are included in the appendixes.

The first world agricultural census (*Internatl. Inst. Agr. [Roma], First World Agr. Census Buls.* 26 (1936), pp. 22; 29 (1938), pp. 12; 30, pp. 22; 33, pp. 35; 35, pp. 157; 36, pp. 79; 37, pp. 139; 38, pp. 93; 40, pp. 47; 41, pp. 25).—These bulletins continue the series previously noted (*U. S. R.*, 79, p. 703). No. 26 presents data for Kenya, No. 29 for Northern Ireland, No. 30 for Japan, No. 33 for Italy, No. 35 for Czechoslovakia, No. 36 for France, No. 37 for Germany, No. 38 for Canada, No. 40 for Mexico, and No. 41 for Uruguay.

RURAL SOCIOLOGY

Rural psychology: A partial list of references, compiled by M. T. OLCOTT (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.* 78 (1939), pp. VI+76).—Included are 183 references on the social psychology of rural life and on the psychology of farm management, or the scientific management of agricultural labor classified as general, attitudes and opinions (with subdivisions on Government and politics, marketing, and relief), family and community life, and farm

labor. References relating to farm youth are omitted. Those on farm labor relate only to scientific studies or "Taylorism" applied to the farm.

The radio and rural research, F. H. FORSYTH. (Univ. Minn.). (*Rural Sociol.*, 4 (1939), No. 1, pp. 67-77).—It is stated that radio, as an instrument of diffusion of urban culture and two-way leveling of rural and urban cultures, has and will have effects which are at least still uncalculated.

Soils, crops, and men: A study in harmony, M. L. WILSON. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 1, pp. 1-10).—The success of scientific agriculture in bringing about highly efficient production of an abundance of material needs is contrasted with the small progress thus far made toward harmonizing this productive efficiency with the unchanged elements of our economic structure.

The good American earth, R. D. BOWDEN (*Rural Sociol.*, 4 (1939), No. 1, pp. 78-87).—The author believes that any proposed remedies sufficient in scope and vitality to effect a realistic solution of the problems of American agriculture must be more drastic and fundamental than can be found in crop reduction formulas, farm debentures, or price-pegging operations. Human and social values are in the center of the picture and involve much more than economic appeasement of landlords.

Science and civilization, O. W. ISRAELSEN. (Utah State Agr. Col.). (*Utah Acad. Sci., Arts, and Letters, Proc.*, 14 (1936-37), pp. 81-89).—The author proposes to meet the challenge of perpetuating agriculture and civilization in arid regions by continuing and enlarging the applications of the sciences to agriculture. He calls attention to the often repeated statement that there has never been any long-continued successful irrigation agriculture in any climate anywhere in the world.

The social effects of recent trends in the mechanization of agriculture, C. H. HAMILTON (*Rural Sociol.*, 4 (1939), No. 1, pp. 3-19).—The high point in the manufacture and sale of farm tractors and other farm equipment in the United States was reached in 1937, when the value of such equipment sold by manufacturers for use in the United States amounted to \$507,140,913. A recent survey of 3,000 farms shows that 40.3 percent of the tractors on farms and ranches in the United States were bought in the 3 yr. preceding 1938. Temporarily, mechanization increases the individual farmer's income; but ultimately, if mechanization actually lowers cash costs he is forced to cut his prices and at the same time pay higher costs for land and fixed costs for land, machinery, and motor fuel. The farmer also loses some of the advantages of mechanization through continually rising standards and costs of living. The author expresses the view that the mechanized farmer and machinery manufacturer have shifted a lot of their costs to the shoulders of the State, and that new governmental functions, such as the social security, farm security, agricultural adjustment, works program, and housing program are the fruit of poorly controlled mechanization in both industry and agriculture. Another social effect of mechanization and other technological changes is that a larger and larger percentage of agricultural products going into the market is being produced by a smaller and smaller percentage of the farm population.

Selected references on the history of agriculture in the United States, E. E. EDWARDS (U. S. Dept. Agr., Library, Bibliog. Contrib. 26 (1939), 2. ed., pp. V+43).—This second edition (E. S. R., 74, p. 712) includes books and articles summarizing the main facts concerning agriculture in the United States or of some major period.

Agriculture and current population trends, C. TAEUBER. (U. S. D. A.). (*Amer. Phil. Soc. Proc.*, 80 (1939), No. 4, pp. 477-489).—Reproduction rates in the farm population indicate an excess of approximately two-thirds above re-

placement needs per generation. The farm population, which includes about one-fourth of the total, accounts for approximately one-third of the births and one-half of the natural increase each year. The net reproduction index, where unity represents permanent replacement in 1930, was only 0.86 for the urban population, but it was 1.37 for the rural nonfarm and 1.69 for the rural farm population. By way of contrast it may be pointed out that 81 of the 98 cities in the United States with a population of more than 100,000 in 1930 had reproduction indexes of less than 1. In the white rural farm population only 41 out of 2,982 counties had indexes of less than 1, and 397 counties had indexes of more than 2.

Agriculture and the farm population (*McGill Univ., Social Res. Bul. 1* (1938), pp. XIX+148, figs. 33).—This is a handbook of selected statistics grouped by counties and regions for Ontario and Quebec.

Rural and agricultural zoning, O. B. JENNESS, J. M. ALBERS, and E. H. WIECKING. (Univ. Minn., U. S. D. A., et al.). (*Natl. Conf. Planning Proc.*, 1938, pp. 92-102).—Including Wisconsin, nine States now have adopted rural zoning enabling acts. The idea is also being given consideration in other States.

Rural zoning and your county (*U. S. Dept. Agr., Bur. Agr. Econ.*, [1939], pp. 13+[1], figs. 8).—This is a popular bulletin presenting the fundamentals of rural zoning in nontechnical terms. Examples of cost of submarginal farms to counties and the results of rural zoning are given. The zoning plan in Bayfield County, Wis., is outlined.

A study of the possibilities of rural zoning as an instrument for improving land use in Hamilton County, Tennessee (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1939, pp. [2]+31, pl. 1).—The meaning of rural zoning, the safeguards necessary in zoning, and the status of rural zoning in Tennessee and other States are described. The land-use problems of Hamilton County and characteristics of the proposed use-districts for the county are discussed.

The annual employment cycle of the farm labor household, P. H. LANDIS and R. WAKEFIELD (*Washington Sta.*, 1938, pp. [1]+24, figs. 4).—This is the report of a study of labor requirements in the Yakima Valley, Wash., and is based on interviews with 345 field laborers. Among other phases it analyzes month by month employment in agricultural and nonagricultural jobs, the nature and extent of employment of women and children in farm laborer households, and the average daily wage return.

Profile of farm wage rates in the Southwest, E. D. TETREAU. (Univ. Ariz.). (*Rural Sociol.*, 4 (1939), No. 1, pp. 36-42).—Farm wage rates per day without board on January 1, 1938, were 3.75 times as great in California as in South Carolina. Wage rates per month without board were 4.17 times as great. The bold western peak was attained by series of rises. Both daily and monthly wages changed gradually from South Carolina across the Old South, with additional gradual increases across the western cotton region, and abrupt increases were registered across New Mexico, through Arizona, and into California. Factors associated with these changes were increases westward in ability to pay high wages; decreases westward in the competition of the family unpaid labor; competitive wage rates in the oil and metal mining industries; differences in the efficiency of workers; and elevation westward of rural standards of living. Additional factors in Arizona were the proportions of Mexicans among farm laborers and competitive urban and rural wage rates on public works projects.

Agricultural labor organization in France, M. CÉPÈDE (*Rural Sociol.*, 4 (1939), No. 1, pp. 26-35).—The first step in legislative regulation of farm labor was taken in 1936 when G. Monnet, as Minister of Agriculture, initiated the "French Agricultural New Deal." Today farm laborers have, as a result

of legislative regulation, regular holidays with pay. Wage and hour regulations of farm labor have been proposed by the *Chambre des Députés*. There is also collective-labor-agreement legislation governing the limitation of working hours and the fixing of wages which is not applicable to agricultural labor, but a bill recently passed called "the Modern Statute of Labor" gives promise of a future bill to apply to farm labor. There are numerous collective farm labor agreements not under governmental control which work excellently in fixing a satisfactory wage scale and system of working hours.

Sickness and medical care among the Negro population in a delta area of Arkansas, I. C. WILSON (*Arkansas Sta. Bul.* 372 (1939), p. 36).—The objectives and procedures in this study were the same as those in the study of the Ozark area (El. S. R., 79, p. 416), except that data were also collected on the condition of the teeth and eyes and membership in burial societies. The data for 1936 were obtained for 226 families by a house-to-house survey, records of the State health department, and from persons professionally connected with health services in the Lakeside Special School District in Chicot County, an area of approximately 225 sq. miles, with a town of 1,582 persons. Some of the findings were as follows:

Of the people 72.5, 74, and 201 percent, respectively, were in good, fair, and poor health. Illnesses during the year averaged 1.1 per capita, and the total cost for medical services was \$3.61 per capita, of which 37.2 percent was for physicians, 29 percent for hospital, 3.8 percent for dental, 0.4 percent for practical nursing, 0.8 percent for graduate nursing, and 2.4 percent for midwifery services, and 10.8 for prescribed and 41.7 percent for unprescribed medicine. Of the families 49.5 percent utilized physicians' services, 8 percent dental services, 3 percent hospital services, 5.8 percent midwifery services, 4.3 percent prescribed medicines, and 9.2 percent unprescribed medicines. High-income families had better health, fewer sicknesses, and a lower infant death rate, and spent less than half as much of their cash income for medical care. Families living over 5 miles from a doctor had nearly as high a proportion of sicknesses attended by a doctor, probably due to the existence of a cooperative medical-care association. Country people had a per capita incidence of disease of 1.2, and town people 0.8. The incidence of illness per capita was highest for cropper families, with tenant and professional families second and third. Over a 5-yr. period 28 percent of all deaths occurred during the first year, the deaths being largely in open-country, low-income, cropper, tenant, and farm-laborer families. The median cost of funerals was \$38.75.

The Catholic rural problem in America, E. V. O'HARA (*Catholic Rural Life Bul.*, 1 (1938), No. 3, pp. 1, 2, 26, 27).—The author discusses the rural problem in a rural Catholic community in the State of Indiana. The greatest reason, he says, why a young man should stay on the farm is that it provides the best opportunity for the family.

The Missouri standard community plan after thirteen years, D. ENSMINGER (Univ. Mo.). (*Rural Sociol.*, 4 (1939), No. 1, pp. 58-66).—This paper gives the results of a partial analysis of the standard community association plan as it was developed in Missouri.

FOODS—HUMAN NUTRITION

Shrinkage and cooking time of rib roasts of beef of different grades as influenced by style of cutting and method of roasting, L. M. ALEXANDER and N. G. CLARK (*U. S. Dept. Agr., Tech. Bul.* 676 (1939), pp. 36, fig. 1).—This bulletin presents data on shrinkage and cooking times of 595 rib cuts of beef roasted by 8 different methods. The cuts ranged in grade from U. S. Choice

to U. S. Plain (formerly called Common), and were cooked as standing and as rolled roasts and by searing and constant-temperature methods. The data of the investigation proper are presented in sections dealing, respectively, with shrinkage and cooking times as influenced by style of cutting beef ribs, by method of roasting, and by grade.

On the basis of their respective weights when ready for the oven, standing roasts shrank less and cooked more rapidly than rolled roasts, but, on the basis of weights of the rolled roasts before boning, the rolled roasts shrank somewhat less than the standing roasts. From the fact that standing roasts were exposed to the oven heat for less total time than rolled roasts and that standing roasts are known to be juicier than rolled, it is suggested that the greater relative shrinkage of the standing roasts came from bone and connective tissue rather than from the edible portion.

The temperature of cooking had the greatest influence on shrinkage and cooking time. When roasts were cooked to the rare or medium stage, as determined by a meat thermometer, the lower the oven temperature the less was the rate of shrinkage and the slower the rate of cooking. At the well-done stage shrinkage was less definitely related to oven temperature. Even with very slow cooking at low temperatures it was not possible to cook meat well done and keep the shrinkage low. Comparisons with paired cuts of constant-temperature roasting with the searing method confirmed the findings of others that searing itself does not reduce shrinkage as was formerly considered the case. Shrinkage, however, was shown to be dependent not on searing alone but on the average oven temperature and on the cut used. A quick sear (265° C. for 20 min.) followed by slow cooking at 125° gave a higher average temperature than 125° during the entire time but lower than a constant temperature of 175°, which was also tested. In the first instance, shrinkage for the searing and nonsearing methods in three-rib roasts were 14.7 and 10.6 percent, respectively, and in the second, 14.2 and 21.1 percent, respectively. Two-rib roasts seared and then cooked at 175° throughout the entire period showed about the same shrinkage—14.1 and 14.7 percent, respectively.

In roasts classified by grade, the data on shrinkage showed that the higher the grade the smaller the evaporation loss and the larger the drippings loss, whatever the style of cutting or method of cooking. This is attributed chiefly to the higher average fat content of high-grade beef. Considerable variation in fat content within the grade is also thought to account for lack of uniformity in shrinkage in like cuts of meat cooked by the same methods. Grade differences in shrinkage were considered of significance only when a large number of the same cuts were cooked by the same method. With cooking time expressed as minutes per pound, the effect of grade on the rate of cooking did not appear to be important, although there was a slight trend toward faster cooking in relation to the weight of rib roasts of U. S. Good than of U. S. Plain beef.

The ash constituents of Australian fish, F. W. CLEMENTS and R. C. HUTCHINSON (*Austral. Jour. Expt. Biol. and Med. Sci.*, 17 (1939), No. 1, pp. 89-92).—Tabulated data are presented on percentages of edible portion of the moisture, total ash, potassium, phosphorus, sodium, magnesium, calcium, iron, copper, and manganese contents and on the calcium:phosphorus ratio of 45 varieties of Australian fish. Data are also given on the comparative consumption of meat and fish in the various Australian States.

The truth about frozen bread, I, II, W. H. CATHCART (*Food Indus.*, 11 (1939), Nos. 2, pp. 68, 69, 109, 110, figs. 3; 4, pp. 200, 201, 233, 234, figs. 3).—In part 1 of this paper the results are reported and discussed with reference to earlier work on the subject of a judging test of bread which had been held for 1 mo. at a temperature of approximately -22° C. and of fresh bread made from the

same formula in the same bread shop. The frozen bread received the preference in 267 percent of the 241 votes and the fresh bread in 56.05 percent. Evaluation of the ballots on a preference basis according to the Platt method of sampling gave a total of 392 points for the month-old bread and 477 points for the fresh bread.

Part 2 consists of a summary of studies by the American Baking Institute of the comparative qualities of bread frozen at different temperatures and held for varying lengths of time and of the effect of wrapping the bread. The subjective tests indicated that wrapped bread frozen at -22° remained "good" for as long as 20 days and salable for about 40 days. Lower temperatures prolonged the period in which the bread was considered good, but when the storage period was continued too long an off-flavor developed. The objective tests, which included determinations of swelling power by the Katz method and compressibility by the Platt method, showed the bread to be stale several days before it was pronounced stale by the judges. Both methods are described briefly.

Effect of calcium on plant tissues, Z. I. KERTESZ. (N. Y. State Expt. Sta.). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 18 (1939), No. 6, pp. 176, 187).—Based on the known ability of calcium salts to unite with pectic acid (demethoxylated pectin) to form insoluble salts or gels, calcium treatment of certain fruits and vegetables before preservation to make the tissues firmer is suggested, with a discussion of the fields where preliminary experiments have indicated the usefulness of such a procedure. These are classified in three groups—canning, freezing, and preserve or jelly making. Under the first, the addition of as little as 0.05 to 0.1 percent of calcium chloride to tomatoes before canning or placing in the can is given as an illustration. In freezing fruits, the treatment should be completed before the freezing commences in order that the calcium might have a chance to diffuse throughout the entire tissue. Calcium treatment is said not only to preserve the natural structure but also to prevent the browning on defrosting of fruits such as apples and peaches. In jelly making, the addition of calcium salts in dilute concentration might not only improve the texture but might also make possible the jelling of fruits which have pectic acid but insufficient pectin. The use of calcium has also made possible the preparation of gels with less than 50 percent sugar.

Making maraschino cherries at home, F. A. LEE (*New York State Sta. Cir.* 184 (1939), pp. 8).—Practical suggestions are given for the selection of cherries, both as to variety and stage of maturity, for making maraschino cherries in the home, with general directions for bleaching and pitting the fruit preliminary to coloring, siruping, and flavoring. Specific directions based on 1 lb. of the pitted cherries are given for the preparation of red and green cherries. Materials and supplies needed are listed, and addresses are given of dealers handling dyes and flavors and cherry-pitting spoons.

Nutritional aspects of milk, W. E. KRAUSS. (Ohio Expt. Sta.). (*Jour. Milk Technol.*, 1 (1938), No. 3, pp. 22-26).—In this paper, which was read at an annual meeting of the International Association of Milk Sanitarians, the attempts which have been made at various experiment stations to increase the content of vitamins C, D, and A in cow's milk through improved feeding, handling, and processing methods are reviewed to illustrate the broader concept of "quality milk" as combining both sanitary and nutritive aspects.

Acid-base balance of cereals and some related food materials, J. DAVIDSON and J. A. LEClerc. (U. S. D. A.). (*Food Res.*, 3 (1938), No. 4, pp. 393-402).—The method developed by the authors for determining the acid-base balance of foods by direct titration of the ash, with corrections for sulfur and chlorine

lost during combustion (E. S. R., 74, p. 156), has been applied to cereals and some related food materials with the following results:

All cereals tested, with the exception of yellow corn, had a slightly alkaline ash but an acid balance; buckwheat, an alkaline ash and slightly basic balance; standard wheat bread, a distinctly alkaline ash but acid balance; and soybeans, jackbeans, and potatoes, a distinctly alkaline ash and base balance. The loss of chlorine during ashing was correlated with the acid or base balance, but the corresponding loss of sulfur could not be correlated with either the acid-base balance of the materials or the alkalinity values of the ash. The transformation of phosphorus into metaphosphate and pyrophosphate during combustion was inversely correlated with the alkalinity of the ash. The orthophosphate content of the ash in the cereals, with the exception of white flour bread, fluctuated from 7 to 54 percent of the total phosphorus. The highest value attained was from barley, which had the highest alkalinity value of all of the cereals when recalculated on the basis of 1 percent phosphoric acid. "It is suggested that the significance of the acid-base balance, if any, besides its possible contribution to the acid-base equilibrium of the animal or human system, may lie also in its effect on the end products of mineral metabolism."

Additional nutritional factors required by the rat, J. J. OLESON, II. R. BIRD, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (Jour. Biol. Chem., 127 (1939), No. 1, pp. 23-42, figs. 7).—The results obtained in studies on several phases of the vitamin B complex, using liver extract in the preparation of all of the concentrates tested, have been brought together in an effort to differentiate further the specific factors of the vitamin B complex.

Four different deficiency symptoms are produced in rats on synthetic diets low in vitamin B complex but adequate in thiamin, riboflavin, choline, and nicotinic acid. These are acrodynia, which can be prevented and cured by crystalline vitamin B₁; paralysis, which is probably the same as previously reported for vitamin B₆ deficiency (E. S. R., 76, p. 565); hemorrhagic disease, which resembles the panmyelophthisis reported by György (E. S. R., 79, p. 713) but which is not prevented by nicotinic acid; and a "spectacled eye" condition, which appears to be somewhat similar to that found in chicks suffering from dermatitis (E. S. R., 75, p. 95). Only the symptoms of acrodynia are prevented and cured by crystalline vitamin B₆.

In discussing the relation of these deficiencies to known members of the vitamin B complex, attention is called to the evidence that eluates, filtrates, and precipitates as designated by different workers may be complex mixtures of active substances. In the studies reported the eluate fraction contains not only the vitamin B₆ but the factors necessary for the prevention of paralysis and the hemorrhagic condition, with very little of the growth factor designated as factor W (E. S. R., 79, p. 137). The filtrate fraction carries in addition to the factor necessary for the prevention of the spectacled eye condition a small amount of factor W and possibly other growth factors, and may also carry the chick antidermatitis factor and nicotinic acid. The alcohol-ether precipitate of Elvehjem et al. (E. S. R., 78, p. 285) and the even more purified fraction of factor W carry vitamin B₆ and probably other factors. It is emphasized in conclusion that each of the factors discussed needs much more study.

The dietary indispensability of valine, W. C. ROSE and S. H. EPPSTEIN. (Univ. Ill.). (Jour. Biol. Chem., 127 (1939), No. 3, pp. 677-684, figs. 4).—By the use of diets devoid of proteins but containing mixtures of highly purified amino acids, as in previous studies of the same author and his associates (E. S. R., 79, p. 183), valine has been shown to be an indispensable amino

acid. The symptoms of valine deficiency in rats are described as an extreme sensitivity to touch and lack of coordination in movement resulting in a staggering gait. The left foreleg is raised and the head retracted. Motion is rotary, either clockwise or counterclockwise. The symptoms are cured rapidly by the addition of valine to the diet.

Further studies of the calcium content of the body as influenced by that of the food, C. S. LANFORD and H. C. SHERMAN (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 381-387).—In this extension of the studies by Toepfer and Sherman (*E. S. R.*, 78, p. 277) of liberal v. minimal adequate intake of calcium upon the body calcium of the offspring of families on such diets, representative male and female young of female rats on the three diets used in the earlier studies (differing only in their content of calcium salts) were selected at from 28 to 30 days and either killed at once or continued on the diet of the mother until 2, 3, 6, or 12 mo. of age. In the rats sacrificed at 1, 2, and 3 mo. of age, those on the two higher levels of calcium intake showed a much more advanced degree of calcification, both in terms of total amount and percentage of body calcium, than those on the lowest calcium intake. At 6 mo. and 1 yr. of age the differences were smaller but still significant. At full maturity the differences in calcification amounted to between 5 and 10 percent. Although the final percentage of body calcium was the same for the two higher levels of intake, the rate of calcification was somewhat greater on the diet providing 0.8 percent of calcium than on that with 0.64 percent. It is noted that experiments still in progress indicate that the higher calcium content achieved on the two higher diets is advantageous throughout life.

Experiments on the relation of nutrition to the composition of the body and the length of life, H. C. SHERMAN, H. L. CAMPBELL, and C. S. LANFORD (*Natl. Acad. Sci. Proc.*, 25 (1939), No. 1, pp. 16-20, figs. 2).—This paper includes, in addition to a brief report of the investigation noted above and a discussion of its significance, preliminary findings on similar studies designed to determine the specific effects of changing the levels of intake of vitamin A alone. Attention is called to the fact that each of the modifications of an already adequate dietary which has increased the length of life of the experimental animals has extended the period of adult capacity and vitality rather than the period of physiological old age.

Vitamin A and carotene, XIII-XVI (*Biochem. Jour.*, 31 (1937), No. 1, pp. 155-187, fig. 1).—In continuation of the series noted previously (*E. S. R.*, 75, p. 885), four papers are presented.

XIII. *The vitamin A reserve of the adult human being in health and disease*, T. MOORE (pp. 155-184).—The problem and general plan of this investigation have been noted from a preliminary report (*E. S. R.*, 68, p. 706) covering 320 of the 950 cases studied. The content at autopsy of vitamin A in the livers of persons between the ages of 15 and 59 was determined by the antimony trichloride color test, and the blue values obtained were converted into International Units per gram of wet liver tissue by multiplying by 0.6. The cases were classified by the primary disease causing death, with deaths due to accidents considered as the nearest approach to normal. The values for each class were grouped into three subclassifications of low, medium, and high, according to ascending vitamin A reserves and the means of the middle subgroups used for comparison.

The median value for 40 cases of accidental death for persons dying within 7 days of injury was 220 I. U. per gram of wet liver. Values above this were found in thyroid diseases of different types with a median of 310 I. U. and in diabetes with a median of 300 I. U. per gram. Somewhat lower values, but still above the level of accidents, were cases of poisoning, 170, and hernia, 160

I. U. per gram. A median value of 110 I. U. per gram was obtained for cancer cases, and this value was typical of a chronic disease which does not appear to have a connection with vitamin A deficiency. The vitamin A reserves in other diseases were classified as at the ordinary disease levels if not more than 20 percent below the cancer median and as below the ordinary disease level if more than 20 percent below. Among the diseases belonging to the second of these groups were bronchiectasis and chronic bronchitis, with a value of 80 I. U. per gram, subacute nephritis and peritonitis 75, enteritis and colitis 74, pneumonia 63, empyema and valvular diseases of the heart 60, septic diseases 51, chronic nephritis 25, and kidney and bladder infections 19 I. U. per gram.

It is recognized that the interpretation of these values "is complicated by the difficulty of deciding in any given disease whether low vitamin A reserves, or the general nutritional subnormality which they might imply, are a factor of etiological significance or merely a secondary effect of the disease. It is clear that in some diseases the power of the organism to absorb the vitamin is impaired. On the other hand, it is noteworthy that many of the diseases showing low reserves in the human being are also frequent terminations to experimental vitamin A deficiency in the animal."

XIV. *The vitamin A reserves of the human infant and child in health and disease*, J. B. Ellison and T. Moore (pp. 165-171).—Similar data are reported and discussed for the vitamin A reserves in the livers of 200 children under 15 yr. of age dying by accidents or from various diseases. The variation in the vitamin A reserves of the liver with age was studied by combining the values for the different age groups dying of all causes. In infants from birth to 4 weeks of age the median value was 17 I. U. per gram, from 5 weeks to 3 mo. 14, 4 to 8 mo. 100, 9 to 18 mo. 73, and 19 mo. to 3 yr. 99 I. U. per gram. The median value for a group of healthy children dying by accident between the ages of 4 mo. and 14 yr. was 130 I. U. per gram. In comparison with this value as a standard, high reserves were noted in tuberculosis, moderate in measles, and low in pneumonia, head infections, septic diseases, and heart diseases. Relatively, these values are in good agreement, particularly in septic diseases, with those found in adults. It is noted that the comparatively high value in measles is difficult to reconcile with the finding of one of the authors that vitamin A therapy had a favorable influence on survival rate in measles.

XV. *The influence of the vitamin A reserve on the length of the depletion period in the young rat*, A. W. Davies and T. Moore (pp. 172-178).—In this re-investigation of the question of the ability of rats to store vitamin A (E. S. R., 73, p. 419), a few animals from two groups of rats from 5 to 7 weeks of age taken from two breeding colonies, one on a diet extremely rich in vitamin A and the other one rather deficient in vitamin A, were killed and the vitamin A reserves of their livers determined by the antimony trichloride color method. The remaining animals in both groups were given a diet deficient in vitamin A, and the exhaustion of their vitamin A reserves was tested by following the weight-increase curves and by killing animals at given intervals and determining the vitamin A content of their livers. After the reserves had been exhausted, as shown by cessation of weight gains and negative results in the antimony trichloride tests, the remaining animals were given halibut-liver oil and the observations continued until weight restoration had taken place.

In the group from the colony on a diet low in vitamin A, weight increases ceased and the antimony trichloride reaction became negative after 5 weeks, while in the other group the weight increases continued for several months and the liver reserves were repeated only gradually. Halibut-liver oil brought about a weight restoration in most cases and an increase in the vitamin A

content of the liver in all cases. These results are thought to "reaffirm the reality of the vitamin A reserve and emphasize the importance in routine vitamin A determinations of using rats which have been reared under conditions ensuring low reserves." Instances of anomalous behavior in rats on high reserves are noted, with the advice that in vitamin A determinations all animals reacting abnormally should be rejected from calculations if lesions sufficient to account for the abnormality are discovered at autopsy.

XVI. *The effect of the administration of large amounts of vitamin A on the vitamin A content of the hen's egg*, E. M. Cruickshank and T. Moore (pp. 179-187).—Experiments at Cambridge University gave evidence that the addition of 10 percent of medicinal-grade cod-liver oil to a low vitamin A basal diet of laying hens approximately doubled the vitamin A potency of egg yolks over that obtained in the basal diet, while the oral administration of 5 g of a vitamin A concentrate in addition to the basal diet increased the vitamin A potency of yolks about 5 times. However, the percentage recovery in eggs of the vitamin A ingested was only 2 and 0.2 for cod-liver oil and the vitamin A concentrate, respectively.

Determinations of the vitamin A content of various organs of hens at the end of the experimental feeding periods revealed a high concentration of vitamin A in the liver and much smaller concentrations in the kidneys, while other organs gave negative results in the case of cod-liver oil feeding and showed only traces of vitamin A in cases of the concentrate feeding.

Destruction of vitamin A by rancid fats, E. J. and J. G. LEASE, J. WEBER, and H. STEENBOCK. (Wis. Expt. Sta.). (*Jour. Nutr.*, 16 (1938), No. 6, pp. 571-583).—The extent of destruction of vitamin A and carotene as present in half-but-liver oil, egg yolk, and alfalfa by various degrees of rancidity produced by heating, aeration and ozonization, and by admixture with various decomposition products was tested by an indirect method involving the feeding of the preparation to rats during a 5-week period and determining colorimetrically the vitamin A content of their livers at the end of the period.

Pronounced destruction of vitamin A took place with definitely rancid fats but not with fresh fats. Fats heated in air destroyed vitamin A in proportion to the duration and time of heat treatment. Lard heated in an open pan for 5 min. at 240° C. had no effect on vitamin A, but heating at the same temperature for 30 or 90 min. completely destroyed the vitamin. Similar heating in nitrogen prevented the subsequent destruction of the vitamin. Various oxidizing compounds which might occur in rancid fats, including palmitic peroxide, ozonized lard, oxidized oleic acid, and oxidized fatty acids of lard, destroyed the vitamin, but oleic acid fed as 10 percent of the ration had no effect. The destructive effect of certain fats was quite out of proportion to the peroxide value. Other possible constituents of rancid fats tested included chemically pure, straight-chain aldehydes and methyl ketones containing from 7 to 12 carbon atoms, oxidized glycerol, glyceric acid and aldehyde, allyl alcohol, acrolein, acrylic acid, pyruvic acid, and propyl aldehyde. None of these proved effective. The components of rancid fats which caused destruction of vitamin A were not removed by distillation with steam or extraction with alcohol, but were rendered inert to a certain extent by heat. The addition of various antioxidants, such as ascorbic acid, hydroquinone, gallic acid, and ethyl gallate, did not prevent the destruction. Vitamin A was not destroyed when given to rats on an empty stomach even when they were maintained on a ration rich in rancid fat, but was destroyed when mixed with rancid fat in the stomach.

Factors affecting the vitamin B₁ content of yeast, P. L. PAVONEK, W. H. PETERSON, and C. A. ELVEHJEM. (Univ. Wis.). (*Indus. and Engin. Chem.*, 30 (1938), No. 7, pp. 802-805).—In addition to data on the yields and vitamin B₁

content of different strains of yeast grown in different media. essentially noted from another source (E. S. R., 77, p. 729), this report contains data on the effect of various additions to a glucose-salts medium on the vitamin B₁ content of a strain of bakers' yeast and on the partition of the vitamin B₁ of grains between residue and wort.

The addition of a vitamin B₁ concentrate, crystalline B₁, nucleic acid, or liver extract to the glucose-salts medium greatly increased the vitamin B₁ content of the yeast. In tests in which the vitamin B₁ was added, from 50 to 100 percent was recovered in the yeast crop. When yeast was grown without aeration, the vitamin B₁ content was about double that produced in an aerated medium, but most of the increase came from the inoculum. About 70 percent of the vitamin B₁ content of the grain was found in the wort. Sterilization of the wort for 45 min. at 15 lb. pressure per square inch appeared to destroy about 20 percent of the extracted vitamin, which, however, was reconstituted by the yeast from the decomposition products.

Quantitative measurement of vitamin B₁ by the thiochrome reaction, H. G. K. WESTENBRINK and J. GOUDSMIT (*Nature [London]*, 142 (1938), No. 3586, pp. 150, 151).—Attention is called to a procedure first described by Westenbrink and Jansen for determining separately by the thiochrome method the two forms of vitamin B₁ now recognized—vitamin B₁ (aneurin or thiamin) and cocarboxylase (aneurin- or thiamin-pyrophosphoric acid). The method depends upon the fact that thiochrome is extracted quantitatively from the aqueous reaction mixture by isobutanol, while the thiochrome-pyrophosphoric acid remains in the aqueous layer. In applying the method to animal tissues, both the aqueous and isobutanol layers show a blue fluorescence even without oxidation by ferricyanide. It is said that this blank fluorescence may be greatly reduced by digesting the tissue proteins with pepsin previous to the adsorption of the vitamin.

The aneurin content of animal tissues was found to be very low as compared with the cocarboxylase content, as shown by the following figures for normal rat tissue: Liver, 7–13 μ g. cocarboxylase, less than 2 μ g. aneurin; muscle, 1.5–5 μ g. cocarboxylase, less than 0.5 μ g. aneurin; kidney, 11 μ g. cocarboxylase, 0.5 μ g. aneurin; brain, 6 μ g. cocarboxylase, less than 0.3 μ g. aneurin.

Quantitative measurement of vitamin B₁ and its phosphoric esters and their synthesis in animal tissues, S. OCHOA and R. A. PETERS (*Nature [London]*, 142 (1938), No. 3590, p. 356).—It is noted that estimates of the two forms of vitamin B₁ designated above have been made on rat and pigeon tissues by the use of yeast enzymes with the same general conclusion that there is more cocarboxylase than vitamin B₁ in most tissues, although the reverse has been found to be true of muscle tissues. The authors call attention to the fact that in their method of determining cocarboxylase only the diphosphoester is measured, while in the method of Westenbrink and Goudsmit it is possible that the monoester also is included. It is announced that under optimum conditions, which are enumerated, liver slices may convert from 25 to 30 percent of vitamin B₁ into cocarboxylase in 30 min. at 88° C.

Basal diets for vitamin B₁ determination, O. L. KLINE, C. D. TOLLE, and E. M. NELSON. (U. S. D. A.). (*Science*, 88 (1938), No. 2291, p. 508).—Sulfite treatment of yeast to destroy vitamin B₁ is recommended for the preparation of rations devoid of vitamin B₁ but containing adequate amounts of the other members of the vitamin B complex. The ration used by the authors consisted of sucrose 71 percent, vitamin B₁-free casein 18, salt mixture 4, fat 5, and cod-liver oil 2 percent, with various proportions of sucrose replaced by the sulfite-treated yeast. This was prepared by adding 400 cc. of 0.1 percent sodium sulfite to 50 gm. of dried yeast in a 500-cc. wide-mouth bottle, introducing SO₂

until a pH of 4 was reached, and then stoppering the bottle and allowing it to stand 5 days, after which the contents were dried on purified casein. Rats fed the basal ration containing 5 or 15 percent of the sulfite-treated yeast and receiving in addition crystalline vitamin B₁ grew as rapidly as animals receiving the same quantity of untreated yeast in the basal diet.

Stability of vitamin B₁ of vacuum-dried animal tissues during storage, A. ARNOLD and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Food Res.*, 3 (1938), No. 4, pp. 367-372, figs. 2).—Several vacuum-dried animal tissues in vacuum-packed cans were tested for vitamin B₁ by the chick assay method of Elvehjem soon after being packed and again after storage for 2 yr. at room temperature. Initial and final values obtained were as follows: Beef kidney, 5 and 4 International Units per gram dry basis; beef spleen, 2 and 2; beef lung, 2 and 1.6; and hog brain, 1.6 and 1.3 I. U. per gram dry basis, respectively. The loss in vitamin B₁ in all but the beef spleen was calculated to amount to approximately 20 percent.

A test for vitamin-C deficiency, M. VAUTHEY (*Lancet [London]*, 1939, I, No. 12, pp. 695, 696).—In the opinion of the author, an accurate estimate of vitamin C metabolism can be obtained by determining the quantity of ascorbic acid excreted in the urine during the hour after the first morning voiding and before food is taken. In normal subjects this amount, designated as "basic ascorburia," has been found to range from 0.92 to 1.04 mg., with an average value of 1 mg. The degree to which these normal values are raised by the administration of large doses of vitamin C can be used as a test for vitamin C deficiency on the assumption that when the value reaches 2 mg. the subject may be considered to be saturated, and the amount of ascorbic acid that must be given to reach this figure is a measure of the subject's vitamin C storage. In practice, ascorbic acid is given intramuscularly in daily doses of 600 mg. for adults and 300 mg. for children at 8 a.m., immediately after the collection of urine for determining the basic ascorburia. In the normal subject this value is reached on the fourth day. If the value is reached on the first day, after only 600 mg. has been given, a very high store of vitamin C is indicated; in 2 days, a high store; in 3 days, a normal store; in 4 days, a slight deficiency; in 5 days, a moderate deficiency; in 6 days, a severe deficiency; and in more than 6 days, true avitaminosis. Certain advantages of the test over those in general use are pointed out.

Complement and ascorbic acid in human scurvy.—An experimental study, E. E. ECKER, L. PILLEMER, J. J. GRIFFITHS, and W. P. SCHWARTZ (*Jour. Amer. Med. Assoc.*, 112 (1939), No. 15, pp. 1449-1452, figs. 2).—A study is reported of the ascorbic acid content and complement titer of the serum of two adult patients with typical scurvy before and during treatment with crystalline ascorbic acid administered orally in graded doses. In both patients the initial complement titers were very low, 0.07 and 0.08 cc. of a 1:15 serum dilution, and the ascorbic acid contents of the serum and urine were negligible. Capillary resistance tests were also negative. The ascorbic acid was given in daily doses of 100 mg. for 2 days, followed by 250, 500, 750, and 1,000 mg., the final dose being repeated daily for another week. Both serum complement and ascorbic acid increased rapidly. The complement reached its maximum at about 0.02 cc. of 1:15 serum dilution on the eleventh day in one subject and on the seventh in the other. At this point the ascorbic acid content of the serum was 1.2 mg. per 100 cc. in both cases. Further dosage failed to increase the complement titer, although the ascorbic acid content of the serum continued to rise. Since the complement activity of the serum can be determined readily, the suggestion is made that the test "may well replace the quantitative chem-

ical estimation of the ascorbic acid in those instances in which both methods cannot be utilized."

The stability of vitamin D (a) as crystalline calciferol in oily solution, (b) in cod-liver and halibut-liver oils, H. M. BRUCE, E. W. KASSNER, and G. E. PHILLIPS (*Quart. Jour. Pharm. and Pharmacol.*, 11 (1938), No. 1, pp. 46-52).—By biological assay with rats the stability of crystalline calciferol in five different oily solvents was determined. The calciferol with a value of 46,000 International Units of vitamin D per milligram had a potency of 41,100 and 45,300 I. U. per gram in two samples of halibut-liver oil and 45,700 and 48,200 I. U. in two of cod-liver oil, respectively, and 32,400 in liquid paraffin with subdilution in the paraffin and 41,100 I. U. per gram in liquid paraffin with subdilution in olive oil. Storage of the calciferol in oil in nitrogen-filled bottles at 0° C. resulted in a loss of vitamin D activity ranging from 28 percent for one halibut-liver oil sample after 14 mo. to 7 percent for one cod-liver oil sample after 19 mo. In two samples of liquid paraffin the vitamin D activity of the calciferol showed gains of 13 and 16 percent, respectively.

Standard methods of vitamin D bioassay of milk, H. T. SCOTT ET AL. (*Amer. Pub. Health Assoc. Yearbook*, 1938-39, pp. 54-59).—This report of a committee of the Foods and Nutrition Section of the American Public Health Association describes in detail a standard procedure for determining the vitamin D content of milk biologically by the line test, incorporating the principles outlined in the *U. S. Pharmacopoeia*, XI, for the vitamin D assay of cod-liver oil. Optional modifications as suggested by the Association of Official Agricultural Chemists are included.

Vitamin K: Its properties, distribution, and clinical importance.—A preliminary report, A. M. SNELL (*Jour. Amer. Med. Assoc.*, 112 (1939), No. 15, pp. 1457-1459).—This preliminary report, prepared at the request of the Council on Pharmacy and Chemistry of the American Medical Association, reviews briefly the literature on vitamin K, designated in an introductory statement by P. N. Leech, secretary of the Council, as "a principle useful in certain hemorrhagic conditions."

Further observations on the use of vitamin K in the prevention and control of the hemorrhagic diathesis in cases of jaundice, H. R. BUTT, A. M. SNELL, and A. E. OSTERBERG (*Mayo Found. Med. Ed. and Res., Proc. Staff Mtgs. Mayo Clinic*, 13 (1938), No. 48, pp. 753-764, figs. 2).—The oral administration of an ether-extracted concentrate of vitamin K from alfalfa meal, together with bile salts, to jaundiced patients was followed by an elevation in the quantitative level of prothrombin in the circulating blood and a reduction in the elevated prothrombin clotting time. When the concentrate and the bile salts were given before and after surgery to 28 jaundiced patients, only 3 bled postoperatively as compared to 9 out of 14 patients who did not receive the preoperative treatment.

Present status of clinical tests for vitamin deficiency, W. H. EDDY ET AL. (*Amer. Pub. Health Assoc. Yearbook*, 1938-39, pp. 42-53).—This report of the American Public Health Association's Committee on Nutritional Problems contains summaries with critical discussion of the clinical tests now in use for detecting vitamin deficiency. Those for vitamin A include dark adaptation and blood vitamin A and carotene tests; for vitamin B₁, thiochrome, yeast fermentation, and bradycardia tests; for vitamin C, blood and urine tests, with hitherto unpublished data, and intradermal tests; and for vitamin D, blood calcium, phosphorus, and phosphatase tests. A list of 74 references is appended.

Biochemistry and pathology of avitaminosis.—III, Enzymic efficiency in deficiency diseases, B. SURE, M. O. KIE, K. S. BUCHANAN, R. T. HARRISON, JR., and R. M. THEIS (*Arkansas Sta. Bul.* 378 (1939), pp. 20).—In continuation

of the series noted previously (E. S. R., 80, p. 140), this bulletin summarizes the results obtained in a long-time investigation, different phases of which have been noted from progress reports and journal articles, on the influence of various vitamin deficiencies on blood and tissue enzymes. The material includes methods employed for the determination of blood and tissue enzymes; enzymic efficiency in deficiencies of vitamin A and of vitamin D (E. S. R., 79, p. 140); influence on the concentration of blood and tissue enzymes of a deficiency of the vitamin B complex (E. S. R., 74, p. 890), vitamin B₁, vitamin G (including riboflavin and vitamin B₂), and vitamin A and the vitamin B complex (E. S. R., 79, p. 140); peptic digestion in vitamin B deficiency; and influence of repeated depletions of vitamins A and B₁ on concentration of digestive enzymes.

The oxygen uptake of tissues in vitamin deficiencies, B. SURE and J. B. DEWITT. (Univ. Ark.). (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 287-298).—The oxygen uptake studies here reported constitute a continuation of a series of investigations on enzymic efficiency in avitaminosis (E. S. R., 79, p. 140). Measurements were made with the Barcroft apparatus, following essentially the technic of Peters et al. as modified by Sherman and Elvehjem (E. S. R., 76, p. 840) of the oxygen uptake of several tissues of white rats on diets deficient in vitamin B₁, all of the components of the vitamin B complex, and vitamin A, respectively. The experiments were carried out by the paired feeding method, with matched litter mates on the same diets, alone and supplemented with the respective vitamins. The results expressed as percentage reduction in oxygen uptake are summarized as follows:

"Deficiency of the vitamin B complex: Kidney, 21 groups, —15 percent; heart, 9 groups, —18 percent. Vitamin B₁ deficiency associated with polyneuritis: Cerebrum, 10 groups, —16 percent; heart, 14 groups, —17 percent; kidney, 19 groups, —19 percent. Vitamin A deficiency: Cerebrum, 13 groups, —14 percent; heart, 7 groups, —19 percent. Neither the extent of loss of weight, the severity of polyneuritis, nor the severity of ophthalmia had any influence on the quantitative reduction of oxygen uptake of either the kidney, heart, or cerebrum of the albino rat on diets deficient in vitamin B complex, vitamin B₁, or vitamin A, respectively."

The results with vitamin B₁ are interpreted as indicating that the disappearance of pyruvate following minute vitamin B₁ additions is associated with a decarboxylation process with acetaldehyde and carbon dioxide as intermediate steps in the carbohydrate metabolism. No theory is advanced concerning the mechanism involved in the reduction of the oxygen uptake of the brain and heart in vitamin A deficiency.

Anemia studies with dogs, V. R. POTTER, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 126 (1938), No. 1, pp. 155-173).—The studies reported were undertaken to investigate further the mechanism by which copper acts as a catalyst for iron in the synthesis of hemoglobin and to attempt to correlate the results obtained in the authors' laboratory in studies on nutritional anemia in rats (E. S. R., 67, p. 90) with those reported by Whipple and associates (E. S. R., 74, p. 731) on hemorrhagic anemia in dogs. Growing dogs were placed on milk diets supplemented only with two drops of percomorph oil a week and after anemia had developed were given supplements of iron and copper in various combinations to a maximum of 30 mg. of iron and 2 mg. of copper daily. Manganese in the amount of 2 mg. daily was given in all cases. Hemoglobin regeneration took place at such a slow rate over a period of 3 mo. as to suggest that either the levels of iron and copper were too low or that a third and unknown factor was lacking. After the

hemoglobin levels had approached normal, two of the dogs were made anemic by bleeding and the rest were maintained further on the whole milk alone. The dogs which were made anemic were unable to form any hemoglobin on milk alone and responded poorly to a dose of 80 mg. a day of iron alone. When 4 mg. of copper per day were given in addition to the iron, hemoglobin regeneration proceeded rapidly. Blood copper determinations showed that an increase in blood copper was not associated with anemia or with a low iron content in the blood but with iron administration. "It is concluded that the canine species should be included among those which require copper for hemoglobin regeneration, and that the need for copper for hemoglobin synthesis is probably a general biological property."

Hemoglobin production in anemia limited by low protein intake: Influence of iron intake, protein supplements, and fasting, P. F. HAHN and G. H. WHIPPLE (*Jour. Expt. Med.*, 69 (1939), No. 2, pp. 315-326).—Experimental observations over a long period of time are reported for the hemoglobin production in four anemic dogs on limited protein intake with iron administered orally and intravenously. These observations show that dogs made anemic by blood withdrawal cannot produce the expected new hemoglobin with iron alone given either orally or intravenously when the protein intake is held at low levels. In the condition of protein limitation, the proteins of salmon muscle, bananas, and carrots are so well utilized that only from 7 to 8 gm. of these food proteins are required to produce 1 gm. of new hemoglobin. These experiments are thought to prove definitely that the iron content of liver is not entirely responsible for its potency in anemia due to hemorrhage.

Iron ascorbate in the treatment of anemia, D. G. FRIEND (*New England Jour. Med.*, 219 (1938), No. 23, pp. 910-912, fig. 1).—In an investigation of the effectiveness of iron ascorbate in the treatment of various types of anemia, 21 patients were studied, using doses of an iron content of 10 mg. intravenously and 200 mg. orally. In 3 patients with anemia due to blood loss, the intravenous injection of iron ascorbate gave a daily hemoglobin increase of 1.2 percent. In 15 patients with anemia resulting from chronic blood loss, nutritional lack, or idiopathic hypochromic anemia, the average daily gain of hemoglobin amounted to 1.1 percent. In 3 patients with hemoglobin values below 50 percent, the daily gain in hemoglobin was 1.5 percent. The red cell count always began to rise before the hemoglobin.

Patients with a history of responding poorly or not at all to iron medication showed no more favorable response to the iron ascorbate, with the exception of one with advanced lymphomatous involvement who had a 10-25 percent increase in hemoglobin and an 8 percent increase in reticulocytes following daily intravenous injections furnishing 20 mg. or more of iron. The progress of the disease was not checked, however, and the patient died 1 mo. after treatment had begun. On autopsy the liver was found to have an iron content of 726 mg. per kilogram, in comparison with normal values of from 100 to 270 mg. In two patients who had become sensitive to iron medication, iron ascorbate was well tolerated.

In four cases of human scurvy, treatment with iron ascorbate in 900-mg. doses for 5 days raised the blood ascorbic acid from 0.2 mg. per 100 cc. to a normal value of 1.3 mg. or more. These results confirm those of Pijoan (*E. S. R.*, 78, p. 573) in indicating definite antiscorbutic properties of iron ascorbate.

Review of nicotinic acid as a therapeutic agent, T. D. SPIES (*Med. Woman's Jour.*, 46 (1939), No. 4, pp. 97-100).—In this review of recent developments in the use of nicotinic acid and certain of its derivatives in the treatment of pellagra, it is emphasized that synthetic nicotinic acid, thiamin hydrochloride,

and riboflavin, although invaluable as therapeutic agents, cannot replace a liberal and well-balanced diet. An extensive list of references to recent literature on the use of nicotinic acid and its derivatives in the treatment of human pellagra and canine blacktongue, and in experimental work on rats, chicks, and pigs is appended.

Failure of nicotinic acid to prevent nutritional cytopenia in the monkey, P. L. DAY, W. C. LANGSTON, and W. J. DARBY. (Univ. Ark.). (*Soc. Expt. Biol. and Med. Proc.*, 38 (1938), No. 5, pp. 860-863).—In continuation of previous studies (E. S. R., 75, p. 426), the authors demonstrated on five monkeys maintained on the vitamin G-deficient diet supplemented by 10 and 50 mg. of nicotinic acid that the factor necessary to prevent nutritional cytopenia in the monkey is not identical with nicotinic acid. "Vitamin M" is proposed as the name of the factor contained in yeast and liver extract which prevents the condition.

Nutritional cytopenia (vitamin M deficiency) in the monkey, W. C. LANGSTON, W. J. DARBY, C. F. SHUKERS, and P. L. DAY. (Univ. Ark.). (*Jour. Expt. Med.*, 68 (1938), No. 6, pp. 923-940, pl. 1, figs. 5).—In a discussion of the findings of the study noted above from a preliminary report, the authors present hematological and weight data on 22 test monkeys. The monkeys receiving the basal diet alone or supplemented by nicotinic acid, riboflavin, and thiamin chloride developed the "vitamin M" syndrome characterized by anemia, leukopenia, and loss of weight. The addition of either 10 gm. dried brewers' yeast or 2 gm. liver extract (Vohn fraction G) to the basal diet supported good growth, normal body development, and a normal blood picture over a period as long as 2 yr. in some of the monkeys.

Food intake and gastro-intestinal motility in the albino rat during chronic CO asphyxia, C. A. PATTERSON, E. SMITH, and H. B. HALE. (Iowa State Col.). (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 3, pp. 509-511, fig. 1).—Chronic carbon monoxide asphyxia was found to decrease the food intake and inhibit gastrointestinal peristalsis in rats.

TEXTILES AND CLOTHING

A new microphotometer for analyzing X-ray diffraction patterns of raw cotton fiber, E. E. BERKLEY and O. C. WOODYARD. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 8, pp. 451-455, figs. 7).—A microphotometer for measuring X-ray diffraction patterns, successfully used to measure patterns of raw cotton fibers, consists of a constant light source focused on the pattern, a measuring device composed of a photoelectric cell and galvanometer system, and a compound mechanical stage for holding and moving the patterns under the light beam while measuring them. The instrument was found to be stable and to show a high degree of precision in repeated measurement of the same X-ray diffraction of raw cotton fibers.

A coefficient of correlation of 0.95 between single X-ray patterns from each of 30 different cottons and their Chandler strength was obtained when the samples were photographed under tension. Lower correlations were obtained when no tension was used. It is pointed out that these results indicate that the X-ray method may be used with considerable precision to estimate the strengths of ungraded raw cotton.

High drafting in cotton spinning: Selected references, compiled by O. M. SHIPLEY (U. S. Dept. Agr., Bur. Agr. Econ., Econ. Libr. List 3 (1939), pp. 12).—Selected references are included from Cotton Literature and its predecessor Current Literature on Cotton.

Report on development and use of rayon and other synthetic fibers, C. H. ROBINSON, R. J. CHEATHAM, D. F. J. LYNCH, and H. P. HOLMAN (*U. S. Dept. Agr., 1938, MC-38, pp. [4]+50, figs. 5*).—This report of a committee from the Bureaus of Agricultural Economics and Chemistry and Soils describes and discusses the manufacturing processes, trends in production, sources of cellulose, the uses and factors influencing the use of rayon, quantities of rayon and other fibers consumed in the United States, uses for which rayon is not suited, and other synthetic fibers.

Breaking strength, elongation, and folding endurance of films of starches and gelatin used in textile sizing, M. S. FURRY (*U. S. Dept. Agr., Tech. Bul. 374 (1939), pp. 36, figs. 11*).—In this continuation of the author's studies on the comparative merits for textile sizing of starches from different sources (*E. S. R.*, 67, p. 349; 69, p. 764; 76, p. 731), breaking strength, total elongation, and folding endurance were measured on films made from wheat, dasheen, corn, rice, sweetpotato, canna, and potato starches and from gelatin used alone and in combination with borax, glycerin, soap, and sulfonated castor oil. Fabrics sized with cornstarch- and gelatin-sizing mixtures were tested for stiffness, breaking strength, and total elongation, and the relation of these fabric properties to those of starch films was studied.

Films of the seven starches used increased in breaking strength as the film thickness increased, but at the same thickness showed no difference in breaking strength. Borax and glycerin added to the pastes decreased, and sulfonated castor oil and soap increased, the strength of the starch films. Differences in strength of fabrics sized with the different starch pastes were due to the amount and distribution of the adhering starch rather than to the variety of starch.

Gelatin films had greater breaking strength than the starch films tested. Borax and sulfonated castor oil increased the strength of the films, soap had little effect, and glycerin decreased the strength. In fabrics sized with cornstarch and with gelatin, borax, glycerin, and, with one exception, sulfonated castor oil increased, and soap decreased the strength.

Cornstarch films showed the least elongation, followed by dasheen, wheat, rice, sweetpotato, canna, and potato starch films. The same order held for fabrics sized with these starches. Glycerin and sulfonated castor oil increased, and borax decreased the elasticity of the films. Gelatin films stretched more than starch films, but fabrics sized with gelatin showed less elasticity than those sized with starch. In general, soap and sulfonated castor oil decreased, and glycerin increased the elasticity of fabrics sized with starch and gelatin mixtures.

The folding endurance of starch films decreased in the order canna, potato, sweetpotato, corn, rice, wheat, and dasheen, and in each starch decreased with increasing thickness. Sizing ingredients decreased the folding endurance of the starch films in the increasing order of sulfonated castor oil, glycerin, soap, and borax. Gelatin films had greater folding endurance than canna-starch films. Borax increased, and glycerin, sulfonated castor oil, and soap decreased the stiffness of both starch- and gelatin-sized fabrics.

The influence of position isomerism in azo dyes upon their fastness to light and washing, M. E. GRIFFITH and W. R. BROWN (*Ohio Sta. Bul. 601 (1939), pp. 21, figs. 8*).—In this study, a series of dyes prepared by D. R. Eberhart by the diazotization of orthosulfanilic acid, metanilic acid, or parasulfanilic acid coupling to form the monoazo dyes with the available naphthylamines and their monosulfonated derivatives was tested to determine the influence of the position of the sulfonic acid group in both the benzene and naphthalene nucleus and the comparative effects of the presence and the position of the hydroxyl and amino groups in the naphthalene ring. Duplicate samples of scoured white wool cash-

mere were dyed with the series of dyes and subjected to light and washing tests and color analyses according to the procedure used in a previous study of another series of dyes (El. S. R., 75, p. 572). The results are reported in tables and graphs and discussed with respect to absorption spectra, exhaustive and washing fastness properties, darkening, light fading, and the utility factor.

Hosiery for women: A buying guide, M. SMITH (*U. S. Dept. Agr., Misc. Pub. 342* (1939), pp. 23, figs. 44).—Consumer information is presented through photographs with brief accompanying descriptions on hosiery selection with respect to suitability for the occasion; types of construction; size and fit; reinforcements; types of cotton, wool, and rayon hose; weights in terms of thread and gage; and on reasons why hose wear out.

MISCELLANEOUS

Federal, State, and local administrative relationships in agriculture, C. R. BALL (*Berkeley: Univ. Calif. Press, 1938, vols. 1, pp. X+461; 2, pp. XI+463-1139*).—The administrative interrelationships arising between Federal, State, and local agencies are discussed. Volume 1 includes a description and discussion of the principles, advantages, and practices of cooperation between official agencies, and chapters dealing with the scope, agencies, and fields of cooperation in research as to climate, soils, agricultural chemistry, and animal industry. Volume 2 deals with plant industries, agricultural education, agricultural engineering, and agricultural economics.

University of Alaska Agricultural Experiment Station, College, Alaska, 1937: Progress report, January–December, L. T. OLDBOYD (*Alaska Sta. Bul. 7* [1938], pp. 35, figs. 11).—The experimental work reported is for the most part noted elsewhere in this issue. Meteorological data are included.

Eighteenth Annual Report [of the Georgia Coastal Plain Station], 1938, S. H. STARR (*Georgia Coastal Plain Sta. Bul. 29* (1938), pp. 157, figs. 22).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Report of agricultural research and other activities of the Western Washington Experiment Station for the fiscal year ended March 31, 1938, J. W. KALKUS (*Western Washington Sta. Rpt. 1938, pp. 46*).—The experimental work reported is for the most part noted elsewhere in this issue.

Fiftieth anniversary, 1888–1938 ([*Connecticut*] *Storrs Sta. Bul. 228* (1938), pp. 64, figs. 11).—This contains the anniversary program of July 27 and 28, 1938, including the following papers: Milestones and Monuments in the History of the Storrs Agricultural Experiment Station, by W. L. Slate (pp. 6-16); The Place of an Agricultural Experiment Station in the Economy of a Commonwealth, by R. E. Buchanan (pp. 17-42); Dreams, Goals, Deeds, by J. L. Hills (pp. 43-51); Wilbur O. Atwater, by C. W. Atwater (pp. 53, 54); Dr. H. W. Conn, by W. M. Esten (pp. 55-57); The Middle Ten Years, 1904-1914, by C. Thom (pp. 59-61); and C. L. Beach, by J. L. Hills (pp. 63, 64).

Fifty years' achievement in agricultural investigations, R. T. PRASCOIT (*Nebraska Sta. Cir. 60* (1939), pp. 79, figs. 29).—Some of the outstanding accomplishments in the various fields are briefly summarized.

Fifty years of progress on dominion experimental farms, 1886–1936 (*Ottawa: Govt., 1939, pp. 158, figs. 62*).—This history of the work and personnel is followed by a review of the various divisions and branch units.

The progress of agricultural science in India during the past twenty-five years, W. BURNS (*Imp. Council Agr. Res. [India], Misc. Bul. 26* (1939), pp. [3]+44).—This is a review of progress in the various fields. A bibliography is appended.

NOTES

Alabama Polytechnic Institute.—A building program embracing 14 new buildings and the first unit of an athletic stadium is under way in connection with allotments of nearly \$1,500,000 of W. P. A. funds. Among the items are \$150,900 for a two-story classroom and laboratory building for the veterinary school, \$100,000 for an addition to the library, \$560,000 for girls' dormitories, \$38,500 for a home economics practice house, a \$100,000 infirmary, a \$100,000 physical education building, a new engineering building, and a \$200,000 general classroom building.

Arkansas University and Station.—Dr. W. R. Horlacher, head of the department of animal industry, has been appointed dean of the College of Agriculture and director of the station and the extension service beginning July 1. H. E. Thompson, head of the U. S. D. A. Farm Security Administration in Arkansas, has been appointed assistant director of the extension service. Other appointments include as technical assistants W. F. Farris and A. Clarence Smith at the Cotton and Rice Substations, respectively.

Delaware University and Station.—George L. Schuster, professor of agronomy and research agronomist, has been appointed director of the station. Dr. J. M. Watkins has been appointed assistant professor of agronomy and assistant research agronomist effective August 1.

Iowa College and Station.—Blair Converse, head of the department of technical journalism in the college and bulletin editor of the station for the past 12 years, died May 18 at the age of 46 years. In the field of journalism he had made a wide acquaintance among newspapermen, editors, publishers of journals, and journalism teachers, and was president in 1937 of the American Association of Teachers of Journalism. He was joint author of several journalism texts. His former students and friends have contributed approximately \$1,500 toward a Blair Converse student memorial loan fund to be available to journalism students attending the college.

Dr. George F. Stewart has been appointed professor of poultry husbandry and will take up a new line of investigation on poultry products. A. J. G. Maw has been appointed assistant professor of poultry husbandry effective August 15 for both teaching and research.

Kansas College and Station.—Willard Hall, the new physical science building named in honor of Dr. J. T. Willard, has been completed at a cost of approximately \$750,000. It is 307 ft. long by 91 ft. wide with a full basement and three floors and a central tower with a fourth floor which will house the meteorological laboratory. The station laboratories are located in the basement and will provide chemical facilities for work in soils, dairying, meats, nutrition, crops, poultry, and related fields.

A swine nutrition laboratory, 109 by 22 ft. in size and of frame construction, has been built at a cost of \$2,500 for use in conjunction with technical studies of the mineral requirements of growing pigs.

Dr. C. O. Swanson, head of the department of milling industry, resigned September 1 to devote his full time to research, and has been succeeded by Dr. E. G.

Bayfield, cereal technologist in charge of the soft wheat quality studies of the U. S. D. A. Bureau of Plant Industry in cooperation with the Ohio Station. Dr. W. H. Riddell, associate professor of dairy husbandry and dairy products, resigned May 15 to become head of the department of dairy husbandry in the Arizona University and Station. Dr. R. K. Larmour, professor of milling industry, resigned June 30 to return to the University of Saskatchewan.

Louisiana Station.—Dr. D. M. Seath, extension assistant professor of dairy husbandry in the Kansas College, has been appointed dairy husbandman in charge of research. I. J. Bocnel has been appointed assistant entomologist vice B. A. Osterberger, who died May 20.

Massachusetts College.—Dr. Frank A. Waugh, head of the department of landscape architecture, has retired with the title of emeritus and has been succeeded by Raymond H. Otto.

Missouri University and Station.—The Rockefeller Foundation has recently made a grant of \$100,000, most of which is to be used for a genetics building. This building is to be constructed at an early date on the main campus, and greenhouses will be provided in connection with it.

A spectroscopic laboratory, fitted up with the most modern equipment, is being established at the university to serve the various departments interested, but particularly those in the College of Agriculture. Dr. V. R. Ellis has been appointed in charge of the laboratory.

Dr. William B. Drew has been appointed assistant professor of botany to give particular attention to ecology and to make a special study of the ecology of pastures in connection with the pasture research under way.

New York State Station.—Action of the State legislature has resulted in a decrease in the total funds available to the station for the current year, exclusive of Federal allotments, of \$24,815.

William P. Wheeler, who joined the station staff as first assistant to the director on January 1, 1888, and retired in 1929 as associate in research (animal husbandry), died April 29.

Cornell University and Station.—E. A. White, professor and head of the department of floriculture and ornamental horticulture, retired July 1 after 26 years of active service.

North Dakota Station.—The following assistants have been appointed: Paul E. Johnson in animal nutrition, Thomas E. Long in agricultural engineering, Phillip Vardiman in animal pathology, and L. D. Sibbitt in cereal technology.

Rhode Island College and Station.—Dr. Burt Laws Hartwell, associated with the institution as chemist and agronomist from 1891 to 1923 and director of the station from 1912 to 1923, died at Edgewood, R. I., on July 13 at the age of 74 years. A native of Littleton, Mass., he was graduated from the Massachusetts College in 1889, received the M. S. degree in 1890, and served as assistant chemist in the Massachusetts Station from 1889 to 1891. He received the Ph. D. degree from the University of Pennsylvania in 1903.

Dr. Hartwell was widely known as an agronomist and chemist, especially in connection with his pioneer studies in conjunction with Dr. H. J. Wheeler. He was elected a fellow of the American Society of Agronomy in 1926 and had also been active in the Society for the Promotion of Agricultural Science and the Association of Official Agricultural Chemists. He was the author of many articles of scientific and popular scope and in recent years had conducted a farm column for the *Providence Journal*.

Virginia Station.—Some 60 botanists, representing, among others, Harvard, Smith, Cornell, New York Botanical Gardens, Ohio State, New Jersey, West Virginia, Cincinnati, Tennessee, North Carolina, North Carolina State, and several Virginia institutions, attended a botanical conference and foray held June 15 to 18 under the auspices of the State experiment station at Blacksburg and the biological station of the University of Virginia at Mountain Lake.

Washington Station.—Recent appointments include E. J. Kreizinger as assistant in farm crops vice Wilford Hermann, resigned; Dwight F. Forsyth as seed analyst vice Dr. Elizabeth M. Hermann, resigned; and C. E. Nelson as assistant in agronomy at the Irrigation Substation.

New Journals.—*Palestine Journal of Botany* is being issued in two series. The Rehovoth series appears semiannually from the Agricultural Research Station at Rehovoth. The Jerusalem series is edited by the botanical staff of the Hebrew University, Jerusalem, and appears quarterly. Its initial issue contains about a dozen articles, among which is The Effect of Hetero-auxin on Root Formation by Cuttings and on Grafting, I. M. Evenari (W Schwarz) and E. Konis; Studies in Palestinian Lentils—II, The Varieties of the Cultivated Common Lentil in Palestine, D. V. Zaitschek; and The Influence of the Water Extract of Wheat Seeds Upon Their Germination and Growth, and The Inhibition of Germination and Root Formation by Copper Sulfate and the Elimination of the Inhibitory Effect, both by G. Mosheov, killed by the Arabs on August 17, 1936, at the age of 23 years.

Chromosoma, a journal for cell nuclei and chromosome research, is being published as Section B of *Zeitschrift für Zellforschung und Mikroskopische Anatomie* by Julius Springer at Linkstrasse 22-24, Berlin, W 9. The initial number contains eight original articles, of which the following are in English: The Measurement of Packing and Contraction in Chromosomes, by C. D. Darlington and M. B. Upcott; The Rate of Movement of Chromosomes on the Spindle, by H. N. Barber; The Nuclear Cytology of the Grass Mite, *Pediculopsis graminum* (Reut.), With Special Reference to Karyomerokinesis, by K. W. Cooper; Structural Hybridity in *Oimes* L., by H. D. Slack; and Competition for Chiasmata in Diploid and Trisomic Maize, by K. Mather.

La Rivista Forestale Italiana has replaced *L'Alpe* and *La Montagna Italiana*, and is published monthly by the State Polygraphical Institute at Roma. The initial number contains several technical articles, among which are the following: The Forest Map of Italy, by A. Brengola; Forest Races and Their Origin, by A. Pavari; The Cultural Treatment of New Forest Plantings, by A. Morendi; Recent Information on the Classification of Poplars, by R. Ciferri; and Economic Conditions Affecting Italian Forestry Production, by P. Carloni.

Boletín de Ganadería is being published by the Ministry of National Economy at Bogotá, Colombia. The initial number contains the following articles: The Consumption, Production, and Dairy Population of Colombia, by R. V. Reyes; The Zebu, by A. L. Herran; and The Work of Our Regional Veterinarians, by C. H. Hernández.

Veterinary Digest is being published monthly for 7 months of the year by students of the Ontario Veterinary College. The initial number consists largely of abstracts of current veterinary literature.

Svenska Vall- och Mosskulturföreningens Kvartalskrift is being published quarterly at Uppsala, Sweden, replacing *Svenska Mosskulturföreningens Tidskrift* and *Svenska Betes- och Vallföreningens Årsskrift*.

EXPERIMENT STATION RECORD

VOL. 81

OCTOBER 1939

No. 4

THE SEVENTH WORLD'S POULTRY CONGRESS

By E. C. ELTING

Dairy Husbandman, Office of Experiment Stations

The significant place which the poultry industry holds in our present-day agriculture was strikingly demonstrated at the Seventh World's Poultry Congress held at Cleveland, Ohio, July 28 to August 7, 1939. The great throngs which crowded the exhibit halls and attended the many public gatherings of the Congress strongly attested the popular interest in this great industry, which in a few years has risen from a relatively lowly rank among agricultural enterprises to occupy one of the foremost positions.

The Congress, held for the first time in the United States, was sponsored by the poultry industry of this country. In accordance with Congressional authorization the President of the United States issued a cordial invitation to those interested in the poultry industry in the various nations of the world to participate. This invitation was widely accepted.

The success of the Congress is directly attributable to the remarkable degree in which all interested agencies were organized into harmonizing groups with a single purpose—that of insuring a truly representative exposition. Special credit is also due to certain individuals, notably Prof. James E. Rice of Cornell University, one of the founders of the World's Poultry Science Association, present first vice president of the association, and general chairman of the general executive board of the Congress, and W. D. Termohlen, secretary general.

Through campaigns conducted by the various State committees and the Canadian National Committee, well over 100,000 one-dollar affiliated memberships to the Congress were obtained, which with a Federal appropriation of \$100,000 went far toward guaranteeing its financial success. In addition, approximately 6,000 full Congress memberships and special Congress memberships admitting to the scientific sessions were sold, an indication of the wide interest in the application of science to the industry. Included in this number were

approximately 225 Congress members from foreign lands and 42 nations. Every State in the United States and Hawaii and Puerto Rico were also represented. Ohio ranked first among the States with over 800 full Congress members, while other States high in this regard were New York, Pennsylvania, Illinois, and Indiana, each having over 300 members.

Official attendance records show that well over 750,000 persons passed through the gates of the exposition. This is truly an amazing record, and probably exceeded the fondest dreams of the sponsors of the Congress. Fortunately, the city of Cleveland, with its spacious public auditorium and extensive exhibit halls, offered excellent facilities.

The great Hall of Industry, with some 225 individual exhibitors, was a representative display, portraying the varied lines of industry associated with poultry production and marketing. The Hall of Nations and States, which contained an imposing array of educational exhibits, represented the combined efforts of 9 U. S. Governmental Departments, 29 States, the insular possessions of the United States, and 9 foreign countries. The material presented in the U. S. Government exhibit was grouped on a subject-matter basis irrespective of the agency concerned. Covering an entire end of the hall, it included sections dealing with breeding, feeding, housing, disease and pest control, marketing, financing, and consumer education, and made a wide appeal throughout the Congress. Attractive and educational exhibits were also presented by Great Britain, Canada, the Province of Quebec, Hungary, Italy, Cuba, the Netherlands, Germany, and Japan. The Hall of Youth featured unique exhibits by college students' poultry science clubs, the 4-H clubs, the Future Farmers of America, the Boy Scouts, and the New Farmers of America.

The Hall of Live Poultry included an exhibit of unusual interest in the International Live Bird Exhibit. This grouping included approximately 750 birds from six foreign countries. The exhibit was noncompetitive and included many unusual types of fowl, some of which had never been shown in this country. The larger portion of this hall was devoted to the competitive live bird show open to breeders from all over the world. This provided an opportunity for visitors to see and study outstanding specimens of the various breeds and varieties of fowl.

High lights of the first day of the Congress were the official opening of the exposition by Henry A. Wallace, Secretary of the U. S. Department of Agriculture and president of the Congress, and welcoming addresses by Harold H. Burton, Mayor of Cleveland, and John W. Bricker, Governor of Ohio. A response by Dr. J. E. Rice,

as general chairman of the Congress, and an address by Karl Vetter of Germany, president of the World's Poultry Science Association, on The World's Poultry Science Association and What It Has Meant to the World's Poultry Industry followed.

The address of Secretary Wallace was entitled The Contribution of the Poultry Industry to World-Wide Abundance. In commenting on the international aspects of the Congress the Secretary stressed the common interests of research workers in the fields of poultry breeding, feeding, and disease control, and at the same time pointed out how complex and varied were the economic problems confronting the poultry industry of the several nations arising from the great diversity of conditions. It was his expressed opinion that an international commodity conference of this nature cannot fail to bring about an increase in mutual understanding of the problems confronting the different nations. In commenting on the rapid progress in poultry technology in recent years, he emphasized the desirability of a well-balanced program between production science and distribution science.

The world-wide application of recent findings in poultry husbandry was further stressed at the general assembly of the second day when the following addresses were presented: Poultry Nutrition and Its Contribution to the Development of the World's Poultry Industry, by Dr. E. Mangold of Germany; Contributions of Genetics to the World's Poultry Industry, by Prof. R. C. Punnett of England; World-Wide Significance of Poultry Diseases and Their Control, by Dr. H. C. L. E. Berger of the Netherlands; and Developments of Marketing and Their Influence on the World's Poultry Industry, by Dr. E. W. Benjamin of the United States.

The scientific sessions of the Congress, aside from one general meeting, were divided into six sections, namely, genetics and physiology, nutrition and incubation, pathology and disease control, economics including marketing, public service and general, and poultry products research. Each of these sections held four or five sessions, with a total of approximately 175 papers scheduled on the collective programs. Relatively large attendance and sustained interest were generally maintained throughout the 5 days of the scientific sessions. About 80 of the papers were contributed by workers from foreign lands, while the remainder were mainly from workers at the various State experiment stations and the U. S. Department of Agriculture. The program as a whole portrayed a cross section of poultry research in progress over the world today. English, French, German, and Spanish constituted the official languages of the Congress. The papers were generally delivered in the language of the authors and are so published in the proceedings, together with

an English summary for those papers printed in a language other than English.

Added features of the Congress were a consumer program, a popular program, a youth program, and a motion picture program. These programs were held daily, concurrently with the scientific sessions, and were well attended throughout the week. The popular program was designed to give recognition to all of the most important phases of poultry husbandry and marketing, with attention directed to the small-flock owner as well as the commercial operator. Under this plan, lectures on popular subjects were delivered during the morning sessions, while the afternoon meetings were divided into smaller conference groups, including sections on feeding and management, breeding, marketing, and diseases. Approximately 100 persons of national and international reputation participated in making these programs highly successful.

The value of the Congress was further enhanced by the meetings of numerous societies and organizations associated with the poultry industry. These included the Poultry Science Association of North America, the American Poultry Association, the International Baby Chick Association, and the American Veterinary Medical Association.

The World's Poultry Science Association, organized in 1912, is the fathering body of the World's Poultry Congress, which has been held regularly at 3-yr. intervals since 1921. The association is an active and continuing organization, encouraging scientific research and investigation among its members. Announcement was made of the election of Prof. J. E. Rice as its president to succeed Karl Vetter of Germany. The new vice presidents include Dr. S. Castello of Spain, J. J. Jordaan of South Africa, Dr. Karl Beller of Germany, Percy Francis of England, C. S. T. van Gink of the Netherlands, Dr. Charles Voitellier of France, and Dr. R. B. Thompson of the United States. Reelected secretary-treasurer of the association was Dr. G. F. Heuser of Cornell University. Dr. B. J. C. te Hennepe of the Netherlands was reelected secretary for continental Europe.

The many individuals who labored so diligently in perfecting plans for the Seventh World's Poultry Congress may be justly proud of their accomplishments. It has undoubtedly made an important and lasting contribution to the progress of this great branch of agriculture and has set a very high standard for similar gatherings in the future.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Biochemical investigations at the New Haven Station] (*Connecticut [New Haven] Sta. Bul.* 421 (1939), pp. 17, 18).—Investigations here noted include tobacco leaf, rhubarb leaf, beet pigment, and protein studies.

[Chemical investigations at the Kentucky Station] (*Kentucky Sta. Rpt.* 1938, pt. 1, pp. 19, 20).—This report notes a colorimetric method for determination of carbon in soil, a modification of the chlorate method to include amide and ammonia nitrogen, and data as to the fluorine content of natural waters, soils, plants, and animals.

[Chemical and bacteriological investigations of the Massachusetts Station] (*Massachusetts Sta. Bul.* 355 (1939), pp. 25, 26, 33, 34).—Bacteriological studies on salt tolerance of fecal bacteria, by J. E. Fuller and R. H. Guiberson; a study of the Eijkman test and streptococci in swimming pool water, both by R. L. France; and chemical investigations on the iron, copper, manganese, and iodine content of fruits and vegetables, by E. B. Holland, C. P. Jones, and W. S. Ritchie, are noted.

[Industrial chemical investigations by the Puerto Rico College Station] (*Puerto Rico Col. Sta. Rpt.* 1938, pp. 26-32, 39, 91).—These are briefly reported upon under the following captions: Jamaica type rum produced in Puerto Rico, by R. Arroyo and M. Manzano; alpha cellulose, an important byproduct from sugarcane, by Arroyo; the mango, its industrial possibilities, chemical and physical characters, and poisonous cassava, both by H. Cruz Monclova; the cassava—study of the cassava root—investigations on the preparation of cassava flour to be used as a substitute of wheat flour in bread making; and the extraction of papaya juice and papain.

Electrokinetics.—XX, Interfacial energy and the molecular structure of organic compounds.—VI, The electric moment of aliphatic alcohols, acids, and esters at cellulose and aluminum oxide interfaces, M. A. LAUFFER and R. A. GOETNER (Minn. Expt. Sta.). (*Jour. Phys. Chem.*, 42 (1938), No. 5, pp. 641-656, figs. 8; *abs. in Minnesota Sta. Rpt.* 1938, pp. 38, 39).—A new cell provided with ground glass joints and designed for use in the streaming potential method greatly improved the ease with which measurements similar to those previously noted (E. S. R., 80, p. 149) could be made. In order to obviate the difficulties encountered in dealing with diaphragms of extremely high resistance and with the measurement of streaming potentials of excessively large magnitude, the electrodes of such diaphragms were shunted through an 11-megohm resistor, thus adding a new technic to electrokinetic methods. Detailed observations are recorded.

A simplified technic for the determination of contact angles and its application to studies on wetting, E. KNEEN and W. W. BENTON. (Minn. Expt. Sta.). (*Jour. Phys. Chem.*, 41 (1937), No. 9, pp. 1195-1203, figs. 2).—The apparatus consisted essentially of an arc lamp, a condensing lens system, an

adjustable stage, and either a picture frame holding a thin sheet of paper or a ground glass. The plane surface being studied was mounted on the adjustable stage and brought into the focus of the condensing lens. The liquid to be tested was then placed on the plane surface, and its image was thus projected onto the screen. Contact angles of a variety of substances were tested and found to agree satisfactorily with the published data.

For a series of sodium salts of the fatty acids the contact angle against paraffin was found to change only slightly up to sodium caprylate. Here the contact angle was approximately 110° (water 115°). From sodium caprylate to sodium palmitate the change in contact angle was pronounced, was essentially linear, and approximated 0° at sodium palmitate. Stearic acid and cholesterol both could be obtained with "polar" and "nonpolar" surfaces.

The method is applicable to the study of the wetting capacity of leaf surfaces and of tooth surfaces and offers promise of yielding valuable information on wetting by water, insecticides, or cleansing agents.

Modern cereal chemistry, D. W. KENT-JONES (*Liverpool: Northern Pub. Co., Ltd., 1939, 3. ed., pp. VII+720, figs. 74*).—It has been the author's purpose "to give the reader a general survey of the application of science to the study of wheat, flour, and, indeed, to some extent to cereals other than wheat." The book is directed especially to the milling and baking industries. The contents are: Composition of wheat, flour, etc.; principal world wheats; cereals other than wheat; colloidal chemistry and hydrogen-ion concentration; flour strength; the technic and the chemistry of the baking process; conditioning and the effect of heat on wheat and flour; composition of mill products; bleaching and flour improvers; dough testing machines; flour for purposes other than bread making; nutritive value of bread; cereal and balanced rations for livestock; the microbiology of cereals; moisture in wheats and cereal products; and methods of analysis.

Peptization of soybean proteins, A. K. SMITH and S. J. ORACLE. (U. S. D. A. and 12 expt. stas.). (*Indus. and Engin. Chem., 30 (1938), No. 12, pp. 1414-1418, figs. 4*).—The amount of nitrogenous matter extracted from oil-free soybean meal by hydrochloric, trichloroacetic, oxalic, sulfuric, and phosphoric acids, and by sodium and calcium hydroxides was determined over a wide range of pH values, and is compared with similar dispersion data for wheat, tepary beans, and Alaska peas.

Microscopy of starch by the Spierer lens, S. WOODRUFF. (Univ. Minn. and Univ. Ill.). (*Indus. and Engin. Chem., 30 (1938), No. 12, pp. 1409-1413, figs. 20*).—The Spierer objective $\times 90$ was found to reveal some details in the structure of the starch grain which the author saw less clearly when using the ordinary $\times 92$ objective, each being used with a $\times 12.5$ eye piece. Photomicrographs are reproduced with the paper.

Fats and oils, lipoids, waxes, resins, ethereal oils, edited by E. BAMES ET AL. (*Fette und Öle, Lipide, Wachse, Harze, ätherische Öle. In Handbuch der Lebensmittelchemie. Berlin: Julius Springer, 1939, vol. 4, pp. XXI+960, figs. 247*).—This volume deals with general analytical methods for food fats; preparation of fats and fat constituents; occurrence, production, and properties of the food fats; microscopical analysis of oil-yielding seeds and fruits; the lipoids; the waxes, resins, ethereal oils, and fruit esters; and the German and non-German legislation concerning fat products.

Chemical constitution of the oils from superior and inferior flaxseeds, R. A. GROSS and C. H. BAILEY. (Minn. Expt. Sta.). (*Oil & Soap, 14 (1937), No. 10, pp. 260-263*).—All seed oils of the Bison flax variety contained a higher percentage of oleic acids and a lower percentage of linolenic acids than the Abyssinian Yellow flax variety. The iodine number appears to be a varietal

characteristic, and the oils have a degree of unsaturation which can be varied by growing the flax under different environmental conditions.

Fruit jellies.—X, The rôle of pectin.—6, Viscosity of dilute pectin solutions as affected by metallic salts and pH, G. L. BAKER and M. W. GOODWIN (*Delaware Sta. Bul.* 216 (1939), pp. 40, figs. 7).—In this continuation of the station's work on pectins (E. S. R., 77, p. 4), it was found that pectin solutions, upon dilution without regard to H-ion concentration, gave viscosity values which agree neither with the relation of Einstein (η_{sp}/C) nor with that of Arrhenius ($\log \eta_r/c$). Upon dilution with adjustment of H-ion concentration to pH 2.6, such solutions gave viscosity values which agree very closely with the logarithmic relationship of Arrhenius ($\log \eta_r/c$). A correctional factor 0.2 in the formula of Arrhenius ($\log \eta_r - 0.2$)/c gave improved constants at concentrations of pectin sufficiently high to produce relative viscosities above 4. Maximum viscosities of dilute solutions of the low-ash pectin were obtained at pH 5.5. Either an increase or decrease of the H-ion concentration from this point caused a decrease in solution viscosity. Above pH 7.0, a decrease in viscosity with increase in alkalinity indicated depolymerization and decomposition of the pectin. Decrease in viscosity with increase in acidity was proportionately less as the concentration of pectin in solution was raised. Indications that specific viscosities vary directly with concentrations of pectin in solution at pH values above 5, $\eta_{sp}/c = k$, were observed.

Low concentrations of salt added to 0.125 percent pectin solutions did not affect solution viscosity below pH 2.75. Above pH 2.75, abnormally high viscosities in the pectin solutions resulted from the formation of complex hydroxides with the salts of copper, lead, ferric iron, and aluminum at H-ion concentrations at which the metallic ion is normally precipitated. Higher concentrations of the salt increased viscosity but in a narrower pH range. Above pH 2.75, the normal viscosity of the pectin solution was lowered by small quantities of those salts whose hydroxides are not precipitated in the pH range 3 to 7. Above pH 7 viscosities were less affected. Salts with dehydrating properties had the greatest tendency to lower viscosity. Results indicate that small quantities of metals present as contaminants in pectin solutions will cause abnormal changes in viscosity in certain pH ranges, but below pH 2.75 the effect will be negligible. Viscosity of dilute pectin solutions could be correlated with jelly grade below pH 2.75. There were indications that otherwise unexplained shifts from high to low viscosity : jelly grade ratios and vice versa are due to the presence of salts and lack of pH control.

The plant alkaloids, T. A. HENRY (*London: J. & A. Churchill, 1939, 3. ed., pp. VIII+689*).—Accumulation of information since the publication of the second edition (E. S. R., 52, p. 309) has necessitated rewriting of the entire book and much enlargement. The alkaloids are dealt with mainly according to a chemical classification, but the grouping according to botanical relationships of the plants in which the bases are found has been followed within the larger chemical groups.

A flexible gas thermoregulator, A. J. BAILEY. (Minn. Expt. Sta.). (*Science*, 86 (1937), No. 2240, pp. 525, 526, fig. 1; *abs. in Minnesota Sta. Rpt.* 1938, pp. 25, 26).—The device described may be made from a glass vessel of any shape for normal conditions of about 250-cc. capacity. The single outlet from this vessel consists of a tube rising vertically, then making a complete loop with the open end again rising vertically. In the lower part of this glass loop, a small amount of mercury is trapped. On the surface of this mercury, a tapered glass rod is floated. In the open end of the outlet tube, the proper adjustments and side tubes are provided for the outlet and inlet of the gas, the valve seat,

the bypass, and the temperature adjustment, combined in two pieces of glass. In operation, expansion of the gas in the bulb unit displaces the mercury in the loop, and in turn the glass floating on the mercury pushes against the valve seat and shuts off the gas supply to the burner. In operation, the temperature could be controlled accurately within a plus or minus 0.1° C.

An inexpensive microchemical filter crucible, A. J. BAILEY. (Minn. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 9 (1937), No. 10, pp. 490, 491, fig. 1).—Finding conventional microchemical filter crucibles either unsuitable or expensive, the author designed a crucible made from Pyrex tubing by molding in the flame to an orifice of roughly conical shape. A small unattached drop of Pyrex glass was used in this orifice as a plug. The final preparation of the crucible consisted of forming the conventional asbestos mat as with Gooch crucibles. The new type of crucible showed practically no loss of weight on ignition and was convenient for manipulations necessary to accuracy.

Laboratory columns packed with silicon carbide, H. J. HALL and G. B. BACHMAN. (Ohio State Univ.). (*Indus. and Engin. Chem., Analyt. Ed.*, 10 (1938), No. 9, pp. 548, 549).—The authors found that ordinary lump silicon carbide is not only cheap and chemically inert, but may be classed with the most efficient column packings now in use. No special care is required in handling, and a fouled packing can be cleaned with boiling acid cleaning solutions if necessary. Since distillations may be made with equal impunity using organic bases, corrosive sulfur compounds, or unstable halides, silicon carbide-packed columns are particularly recommended for general laboratory use.

The determination of the thermal conductivity of gases, C. M. MASON and R. M. DOE. (Univ. N. H.). (*Jour. Chem. Ed.*, 14 (1937), No. 4, pp. 182-184, figs. 2).—The authors have modified a familiar method, rendering it useful for use in the elementary physical chemistry laboratory. Directions for the construction and use of a simple thermal conductivity cell are given. The necessary calculations are indicated, and some results are stated.

Some critical studies of the phenoldisulfonic acid method for the determination of nitrates, E. M. ROLLER and N. MCKAIG, JR. (U. S. D. A. and S. C. Expt. Sta.). (*Soil Sci.*, 47 (1939), No. 5, pp. 397-407).—Clarification of the extract was accomplished most satisfactorily with calcium sulfate solution. The addition of calcium carbonate to the extract before evaporation prevented a loss of nitrates due to acidity and was the most satisfactory basic material tried. Ammonium hydroxide caused a loss of nitrates. The most satisfactory sample : water ratio was 1:2 by weight. The best time of contact of sample with water was 5 min. Concentrated hydrogen peroxide was the most effective decolorizing agent. Commercial superoxol was found generally to contain nitrates and was purified by vacuum distillation. When hydrogen peroxide was heated with common bases, peroxides were formed. These reacted with phenoldisulfonic acid, producing a pink-to-brown color upon neutralization of the solution with ammonium hydroxide. The color was prevented by decomposing the peroxides of the residue with carbonated water and evaporating to dryness to expel all H_2O_2 vapor before adding phenoldisulfonic acid. Spontaneous ignition of the residue, which is likely to occur when the extract is evaporated to dryness with hydrogen peroxide, and discoloration of the solution were prevented by the carbonated water treatment. Calcium carbonate was the only basic substance tested which produced a white residue and did not form a peroxide. Concentrated hydrogen peroxide oxidized ammonium hydroxide to nitrate but did not appreciably oxidize the nitrogen in several types of nitrogenous organic compounds.

A modified procedure, based on these observations, is detailed.

Comparison of methods of determining small quantities of HCN, O. H. COLEMAN and R. GARDNER. (Colo. Expt. Sta.). (*Soil Sci.*, 47 (1939), No. 5, pp. 409-413).—Of the methods studied, the modified alkaline method (E. S. R., 78, p. 446) of determining small quantities of HCN gave the most reliable results. The tin condenser is satisfactory for distillations of solutions of HCN. Autolysis in an Erlenmeyer with the resultant transfer of plant material to the distilling flask causes no apparent loss in HCN if the transfer is made with a reasonable amount of care. Good results were obtained by the modified alkaline method by titrating the entire distillate instead of an aliquot.

The detection, identification, and gravimetric determination of pentosans and pentoses, A. J. BAILEY. (Minn. Expt. Sta.). (*Mikrochim. Acta*, 2 (1937), pp. 35-46).—The utilization for identification of crystal habits, optical properties, and physical constants of sugars and their derivatives is suggested. A procedure for crystal identification by optical means is outlined. The methods of sugar estimation applicable to pentoses are discussed, and the errors of the standard pentosan determination are pointed out. An accurate gravimetric macrodetermination of pentoses was developed and reduced to a microbasis. This requires only equipment available in the laboratory, and high accuracy and precision were obtained on 3-mg. samples of wood and from 0.5- to 1-mg. samples of pentose materials.

Determination of moisture in wood chips, sawdust, and pulp, A. J. BAILEY. (Minn. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 9 (1937), No. 12, pp. 568, 569, fig. 1; abs. in *Minnesota Sta. Rpt.* 1938, p. 26).—The author substitutes tetrachloroethylene for toluene in the Bidwell-Sterling distillation method (E. S. R., 53, p. 805), thereby avoiding fire risk, causing the sample to float so that it is protected from overheating, and providing an easily read meniscus. The trap was modified so that the heavier tetrachloroethylene could be drained at will from underneath the water back to the flask.

The calcium-phosphorus ratio of the skins of canning peas and its relation to maturity, D. W. BOLIN and W. SCHROEDER. (Idaho Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 53 (1939), No. 8, pp. 631-636).—The authors present data which show a marked variation in the calcium and phosphorus content of the pea skin with the stage of maturity. Analyses of the skins showed that the calcium content and the calcium-phosphorus ratio increase, and the phosphorus content decreases, with approach toward maturity.

Manufacture of sweet potato starch in the United States, H. S. PAINE, F. H. THURBER, R. T. BALCH, and W. R. RICHIE. (U. S. D. A.). (*Indus. and Engin. Chem.*, 30 (1938), No. 12, pp. 1331-1348, figs. 18).—The chemical research and engineering involved in the erection and operation of a factory for production of starch from sweetpotatoes are described. The properties of sweetpotato starch were studied and evaluated from standpoint of use in various industries. The value of the byproduct pulp as cattle feed was established. A new method of dehydration was evolved, making possible the storage of sweetpotatoes and year-round operation of starch factories.

The cooking process: Butanol cooking of hardwoods and softwoods, J. M. McMILLEN, R. A. GORTNER, H. SCHMITZ, and A. J. BAILEY. (Minn. Expt. Sta.). (*Indus. and Engin. Chem.*, 30 (1938), No. 12, pp. 1407-1409).—The authors pulped six hardwoods and six softwoods with a mixture of equal volumes of water and normal butanol. They found that the hardwoods were all pulped satisfactorily, but the softwoods were only partially pulped. The softwoods have a much greater proportion of lignin resistant to butanol delignification than do the hardwoods. Birch and basswood are more efficiently delignified, and balsam is less efficiently delignified than other woods in their

respective classes. Aspen cellulose is recovered in higher yields than is the case with other hardwoods. All of the hardwoods yield pulps which, insofar as the analyses are concerned, would be commercially satisfactory. None of the softwoods yielded pulps with analyses which would be satisfactory commercially.

The cooking process.—X, Pulping wood with alcoholic nitric acid solutions, S. I. ABONOVSKY and R. A. GORTNER. (Minn. Expt. Sta.). (*Indus. and Engin. Chem.*, 29 (1937), No. 12, pp. 1431-1434, figs. 4).—In continuation of previous work (E. S. R., 77, p. 154), aspen and jack pine sawdust and chips were refluxed with aqueous and alcoholic (ethyl and *n*-butyl) solutions of nitric acid, and the acid-treated wood was boiled with dilute sodium hydroxide solutions. The concentrations of the acid and alkali as well as the duration of the treatment were varied. Cooks were also run with mixtures of aqueous and alcoholic nitric acid and with alcoholic solutions of sulfur dioxide and lithium bisulfite. The alcoholic nitric acid solutions gave much higher yields of good pulp than were obtained with the aqueous acid under similar conditions. Increasing the concentration of the acid resulted in lower total yields but gave larger yields of screened pulp. Dilution of the alcoholic solutions with water had little effect on the yields of pulp. Jack pine did not pulp as readily as aspen. Soda ash was not as efficient as sodium hydroxide in removing the compounds formed by the action of nitric acid on wood.

Adhesive properties of lignin and cellulose, A. J. BAILEY. (Minn. Expt. Sta.). (*Paper Indus.*, 19 (1938), pp. 1274-1276).—Removal of cellulose from thin sections of dense fiberboards destroyed the structure, while removal of lignin effected little change. Thin sections of paper containing high and low lignin contents behaved similarly, as did also sheets of the same paper. Fiberboards were prepared from purified pulp by pressing at room temperature and had properties similar to the commercial product containing lignin. The relation of these findings to industrial processing is pointed out, and changes, such as beating and chemical gelatinization, are recommended to increase strength.

Four new products made from lignin in wood waste (*Jour. Forestry*, 37 (1939), No. 6, p. 494).—Notice is given of the successful preparation of four byproducts obtained from lignin by treatment of the material under heat and pressure in the presence of H and a catalytic agent.

Research for new uses for farm commodities, T. H. HOPPER (*North Dakota Sta. Bmo. Bul.*, 1 (1939), No. 5, pp. 20-22, fig. 1).—This is an outline of the nature, organization, and projected work of the regional research laboratories (E. S. R., 80, p. 289).

AGRICULTURAL METEOROLOGY

Meteorology and agriculture, C. F. SABLE. (U. S. D. A.). (*Bul. Amer. Met. Soc.*, 20 (1939), No. 4, pp. 154-160).—In this address are discussions of investigations of long-range weather and crop forecasting, of the relationships of weather to growth and production of crops, and of agro-meteorology, with 14 literature references.

Recent trends in weather service, W. R. GREGG. (U. S. D. A.). (*Bul. Amer. Met. Soc.*, 20 (1939), No. 4, pp. 165-169).—A brief review.

Progress in applying new synoptic aids to day-to-day forecasting, R. H. WRIGHTMAN. (U. S. D. A.). (*Bul. Amer. Met. Soc.*, 20 (1939), No. 4, pp. 169-177, figs. 6).—A brief summary of recent advances.

Hydro-meteorological aspects of flood control and forecasting problems, M. BERNARD. (U. S. D. A.). (*Bul. Amer. Met. Soc.*, 20 (1939), No. 4, pp. 160-165).—A general discussion.

Indiana regional contrasts in rainfall intensity and some apparent effects thereof. S. S. VISHKE (*Ind. Acad. Sci. Proc.*, 53 (1937), pp. 147, 148).—An abstract.

Rainfall and run-off of New England. A. T. SAFFORD (*Jour. Boston Soc. Civ. Engin.*, 26 (1939), No. 2, Sect. 2, pp. 101, figs. 23).—This monograph is the result of an effort by the author to restudy the data on rainfall and run-off of New England and bring up to date the report¹ made in 1921. The figures obtained for the subsequent 15 yr. have been added to that material and the conclusions of the former report tested out from the old and new material and strengthened or questioned, and certain new conclusions drawn which are offered for discussion. The topics discussed are drought conditions in the United States, precipitation in the United States and on the Pacific Coast, calendar v. climatic years, precipitation—New England (including Weather Bureau and private records, 11 selected stations, comparison of records, average precipitation, dry periods and deficiencies, wet periods and excesses, dry and wet continuous 10-yr. periods, dry and wet cycles, and good and poor water power years), run-off (including New England run-off figures, New England streams by years chronologically and in order of dryness, run-off v. drainage area, Connecticut River tributaries—west v. east sides, good and poor water power years, and streams with large v. those with small storage), duration curves, evaporation, snow cover, effect of reforestation, and ratings.

A study of a century and more of precipitation records for 11 stations and a half century for many more appears to indicate that there is not much difference in the amount when averages for 10 or more years are compared. If there are cycles depending on conditions not now well known, it is believed that it will be many years before this can be demonstrated.

Dew-point hygrometer for use at low temperatures. C. A. WINKLER (*Canad. Jour. Res.*, 17 (1939), No. 2, Sect. D, pp. 35-38, fig. 1).—An apparatus is described providing for slow cooling of a metal mirror by circulating over it liquid from a vessel in a thermoregulated bath and the use of multiple thermocouple elements contained in the mirror, the set-up enabling dew-point temperatures to be approached gradually and to be accurately determined. Precise measurements of relative humidity at low temperatures, with the moisture content of the air low, therefore become possible. The author reports a precision of ± 0.5 percent relative humidity as readily attainable down to -15° C.

Comparative evaporation rates in normal forest, open park, and cleared areas. J. D. WILSON and R. R. PATON (*Ohio Sta. Bimo. Bul.*, 198 (1939), pp. 64-69).—Black and white atmometers were run for 4 yr. in a cleared area of uninterrupted air movement and sunshine, an open park in which there were scattered large trees but no undergrowth, and a normal forest which usually consisted of a stand of second growth trees of medium density in which there was the average amount of undergrowth. Use of the two types of atmometers made it possible to determine the influence of the light factor on evaporation independently of the other factors. In an average of the data from four stations, the radiant energy (B-W) which penetrated to the 4-ft. level in a normal forest and in a parklike area was only 10.5 and 41 percent, respectively, of that in the open, over a 16-week period from \pm June 1 to September 20. B-W values made up 29.6, 18.8, and 0.1 percent of the total loss from the black atmometer in the cleared, open park, and normal forest areas, respectively. White atmometers, which may be assumed to measure the evaporation due to all factors other than sunshine, lost 77 and 46 percent as much water in the open park and normal forest areas, respectively,

¹ *Jour. Boston Soc. Civ. Engin.*, 9 (1922), No. 8, pp. 167-212, pls. 6, figs. 10.

as in the cleared, or open, areas. The first value given represents the average of two stations and the latter an average of four.

A volumetric apparatus for measuring dew [trans. title], H. MROSE (*Ztschr. Angew. Met., Wetter*, 56 (1939), No. 5, pp. 137-149, figs. 3).—The author discusses the difficulty of measuring dew, reviews the earlier methods, describes and illustrates the apparatus here presented, and discusses the source of dew and the value of measuring it. There are nine references.

The droughts of 1930, 1934, and 1936 in the Corn Belt and associated areas, J. E. SWITZER (*Ind. Acad. Sci. Proc.*, 53 (1937), pp. 149-161, figs. 2).—These three droughts were widespread in the central part of the United States, but decreased in intensity and destructive effects towards the north and the south. The year 1930 was relatively moist in the western Great Plains area. In general, each drought was more devastating than the preceding one, and new high temperature records were established in most of the States. The intensity of the droughts was, in general, proportional to the extremes of high temperature and their duration. Excessive evaporation was as important a factor in the crop deterioration as was the deficiency in precipitation.

Duststorms and dust walls [trans. title], H. KOSCHMIDDER (*Naturwissenschaften*, 27 (1939), No. 8, pp. 113-122, figs. 8).—The author defines the terms, presents (with copious classified bibliography) the geographic distribution of duststorms, summarizes data on duststorms in the United States, the Sudan, the Sahara, Syria, Palestine, Mesopotamia, Iran, and Australia, and finally discusses warm and cold air duststorms and dust walls in general.

The agricultural significance of snow [trans. title], J. BRÜTHGEN (*Ztschr. Angew. Met., Wetter*, 56 (1939), No. 4, pp. 111-122, figs. 8).—A general discussion of the agricultural relationships in the broad sense.

SOILS—FERTILIZERS

An introduction to soil science, B. ISEUR (*Boston: Agr. Sci. Pub. Co.*, [1938], pp. XI+[3]+239, figs. 47).—"There are so many details included in most texts that the average student fails to gather the fundamentals. With this fact in mind, the author has attempted to set forth the fundamentals of soil science and has left with the instructor the filling in of whatever detail and illustration he may deem necessary."

The contents are a foreword; chapters 1 to 16, having the titles historical, some elements of chemistry, the origin of the earth, the rock-soil cycle, soil formations, soil separates and soil classification, soil texture and soil structure, tillage and tillage implements, soil surveys, plant nutrition and composition, organic matter and micro-organisms, soil acidity and lime, soil moisture, drainage and drainage systems, crop rotations, and fertilizers, respectively; soil diagnosis and soil diagnosis key; exercises; and a general index. The chapter on tillage and tillage implements is by C. H. Thayer (Mass. State Col.).

[Soil investigations by the New Haven Station]. (Partly coop. U. S. D. A.). (*Connecticut [New Haven] Sta. Bul.* 421 (1939), pp. 41-43).—These have included pasture soil studies and studies on soil management for vegetable crops, losses from the soil by leaching, and soil treatments in the forest nursery.

[Soil and fertilizer work at the Kentucky Station] (*Kentucky Sta. Rpt.* 1938, pt. 1, pp. 20, 21, 37, 38, 39, 54, 55).—This report discusses work on boron and other minor elements and soil fertility, field tests of phosphates, the effect of certain cropping treatments on the amount of nitrogen removed by cropping and drainage from lysimeters, greenhouse tests of availability of phosphates, the effect of phosphorus fertilization on the chemical properties of soils,

and lime and fertilizer experiments on eroded soil and soil of sandstone origin.

[Soil investigations of the Massachusetts Station] (*Massachusetts Sta. Bul. 355* (1939), pp. 12-14, 14, 15, 19, 20, 34, pl. 1).—This report contains notes on rates of decomposition of various sawdusts, shavings, cacao hulls, and peanut hulls by J. Zak and W. S. Eisenmenger; the use of nitrogen as an aid in decomposing old sod, by K. J. Kucinski, W. H. Bender, and Eisenmenger; the absorption by lettuce and cabbage plants of chemical elements important in human nutrition and magnesium requirements of plants, both by Eisenmenger and Kucinski; relationships of natural vegetation to physicochemical properties of soils in Massachusetts, by W. S. Colvin and Eisenmenger; soil erosion in Massachusetts, by Kucinski and Eisenmenger; effect on pH from adding sulfur to a soil, by R. W. Donaldson, W. G. Colby, and H. M. Yegian; the comparative nutritive effects of copper, zinc, chromium, and molybdenum, by H. R. DeRose, Eisenmenger, and W. S. Ritchie; and lignin and its relation to the absorption of minerals by plants, by E. Bennett.

[Soil investigations of the Wisconsin Station] (*Wisconsin Sta. Bul. 443* (1939), pp. 53-56, fig. 1).—This report contains brief notes on soil boron determination by means of the quinalizarin color reaction, by K. C. Berger and E. Truog; fertilizer value of activated sludge, by C. J. Rehling and Truog; and management of very shallow soils, by A. R. Albert.

[Soil Survey Reports, 1932 and 1936 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1932, No. 35, pp. 40, figs. 2, map 1; 1936, No. 1, pp. 67, pls. 2, figs. 3, map 1*).—These surveys were made in cooperation with the respective State experiment stations: 1932, No. 35, Armstrong County, Pa., R. T. A. Burke et al.; and 1936, No. 1, Mason County, Mich., C. H. Wonser et al.

Preservation of small core soil samples, R. W. GERDEL (U. S. D. A.). (*Soil Sci.*, 47 (1939), No. 5, pp. 353-355, pl. 1).—A method for preserving small core soil samples by impregnation with an unpolymerized plastic (commercially available) and subsequent polymerization has given very satisfactory results. This method of preservation permits frequent handling of the sample without disintegration of the structure, and a suitably collected and preserved series of samples permits direct comparison of structural changes throughout the season. The preserved samples retain almost all of the structural features which are observed in the fresh field samples, and in some soils these structural differences are greatly emphasized by this process of preservation. Since the plastic used is slightly water soluble in the unpolymerized state, it is miscible with the soil solution and apparently does not produce serious structural changes. Ground and polished faces of six cores so preserved are shown in a photograph.

Chemical characteristics of the soils of the rice area of Louisiana, J. F. REED and M. B. STURGIS (*Louisiana Sta. Bul. 307* (1939), pp. 31, figs. 6).—The soils of the Iberia and Lake Charles series show many resemblances. The theory of a common alluvial origin appears to be well founded. The two series might be united. The Calcasieu and Katy series developed on older terraces are very similar and should be united.

Flooding a virgin Crowley soil with distilled water caused increases in the pH and in the contents of soluble sodium and magnesium. Flooding also caused increases in the contents of iron and silica in the displaced solution. It was found that continual flooding and cropping to rice over a period of years breaks down to a measurable extent the water-stable aggregates of the soil and causes deflocculation. Improvement in the physical condition of a cultivated Crowley soil by various treatments was detected by measurements of the rate of percolation of water through the soil and by aggregate analysis. Leguminous organic

matter was the most effective treatment for physical improvement. Applications of gypsum, lime, and elemental sulfur were much less effective.

Soil macrostructure as affected by cultural treatments, R. C. COLE (Hilgardia [California Sta.], 12 (1939), No. 6, pp. 427-472, figs. 26).—The author elaborated a method for measuring quantitatively changes in the size distribution of aggregates and the volume weight of the soil and found that, in general, plowing caused a decrease in cloddiness and volume weight unless performed at excessive moisture contents. Harrowing usually broke up some clods. Disk and spring-tooth harrows seemed more effective than spike-tooth harrows in reducing cloddiness. Rolling and leveling increased the volume weight and had a pulverizing effect on the very dry soils, but moderately moist soils usually showed increased cloddiness after these operations. The cloddiness of soils worked up to a fine, highly pulverized condition was greatly increased by irrigation, often to a point far in excess of that before any tillage. Tilled areas that were left cloddy showed some increase in cloddiness, but not so much as those that had been thoroughly pulverized. Winter rains appeared often to have as great an influence on the size distribution of aggregates as the tillage operations or irrigations.

Capillary tension as a measure of the pore space unoccupied by water in some dense orchard subsoils, D. BOXTON. (Cornell Univ.). (Soil Sci., 47 (1939), No. 5, pp. 347-352, figs. 2).—On the basis of this study, it is concluded that the tensiometer can be used with caution to estimate the pore space unoccupied by water in certain dense orchard subsoils. Because of variations in soil texture and structure, the calibrations apply, however, only to apparently uniform layers in restricted areas and even then are subject to the possibility of error. Although the range of pore space covered by the tensiometer is small, it seems possible that the most critical range is covered insofar as the aeration of these soils is concerned.

Some factors influencing the heat of wetting of soils, H. A. WADSWORTH. (Hawaii Expt. Sta.). (Soil Sci., 47 (1939), No. 5, pp. 385-390).—A critical study of the behavior of two soils in determinations of their heat of wetting showed that the results of determinations of heats of wetting are of qualitative interest only unless unusual precautions are taken. The conventional cooling of oven-dried samples in ordinary desiccators may permit the adsorption of enough water prior to the determination of the heat of wetting to reduce materially the value of the result. The heat of wetting of a sample of soil at a specified moisture content appears to be a function of the temperature at which the determination is made. Increases of temperature at the time of determination result in decreases in the heat of wetting, and conversely.

Subsoil moisture under semiarid conditions, J. S. COLE and O. R. MATHEWS. (Coop. Mont., N. Dak., Nebr., and Kans. Expt. Stas.). (U. S. Dept. Agr., Tech. Bul. 637 (1939), pp. 71, figs. 14).—The authors find that within the zone of normal wheat-root development the soil of semiarid regions is usually dry at harvest time. If loss through weeds is prevented, however, accumulation takes place from harvest until the spring crop reaches the stage of a transpiration rate exceeding the rate of moisture supply by precipitation. "As a general rule, the entire annual cycle of charge and discharge is confined to only a portion of the zone where roots can develop freely, and no water reaches the underlying subsoil. In a few exceptional years at a few stations the entire root zone fills with water and a small quantity penetrates beyond the reach of wheat roots.

"The addition of fallow to the cropping system lengthens the period of water accumulation by a year, permits the wetting of the entire root zone in more cases than under continuous cropping, and increases the number of times when water reaches the underlying subsoil.

"Water charge and discharge are much the same under sod as under continuous grain production, although available water is removed completely to a lower depth under sod than under grain, probably because of the presence of deep-rooted perennial plants in native sod. The time element limits the depth to which the roots of annual crops can remove all the available water."

The subsoil was found to be generally less dry under continuous grain production than under sod. "The net result of the production of annual crops in the semiarid section has been an increase rather than a decrease in subsoil water."

A permanent loss to New England: Soil erosion resulting from the hurricane, H. H. BENNETT. (U. S. D. A.). (*Geog. Rev.*, 29 (1939), No. 2, pp. 196-204, figs. 14).—The author considers that erosion damage to productive soils may equal the total of all other storm damage. Where protective measures were in use damage was much less or was prevented entirely.

Erosion and related land use conditions on the Scantic River watershed, Connecticut-Massachusetts, P. H. MONTGOMERY (U. S. Dept. Agr., *Soil Conserv. Serv.*, 1939, pp. 27, pls. 21, fig. 1).—The Scantic River rises about 12 miles southeast of Springfield, Mass., and flows southwest to the Connecticut River about 7 miles north of Hartford, Conn. The watershed comprises about 71,129 acres.

Of the entire watershed, 8.2 percent showed no apparent erosion, 66.7 showed slight erosion, 20.6 moderate, 1 severe, and 0.1 percent very severe. The corresponding figures for cropland are 0.1, 65, 31.2, 0.7, and 0 percent. Like data were obtained from idle land, pasture, and woodland. Control measures are discussed, and a description of soil types is appended.

Soil and alkali problems. (Coop. U. S. D. A. et al.). (*Wyoming Sta. Rpt.* 1938, pp. 8, 9).—A year's record of the movement of total salts and of nitrates in the waters of the Big Horn River is noted.

Effect of dilution on the water-soluble and exchangeable bases of alkali soils and its bearing on the salt tolerance of plants, W. P. KELLEY. (Univ. Calif.). (*Soil Sci.*, 47 (1939), No. 5, pp. 367-375).—"The total amount of Na that is removed from an alkali soil by displacement procedure may be a few milliequivalents per 100 gm. less than that removed by 1:5 water extraction. This does not justify the conclusion that the exchangeable Na, as ordinarily determined, is seriously in error. The factors which influence the determination of exchangeable Na in alkali soils are so varied and numerous that a high degree of precision of method will probably serve no useful purpose. Dilution appears to affect to less extent the determination of water-soluble Ca and Mg than that of Na. Among the common anions of alkali soils, the total amounts of HCO_3 and SO_4 found are likely to be the most markedly affected by dilution, whereas Cl was scarcely affected in the soils investigated. The same was probably also true of NO_3 ."

It is pointed out that the solution displaced from an alkali soil differs substantially from the solution at the growing root-soil particle contact. The bearing of the data obtained on salt tolerance studies is briefly discussed.

The determination of the organic base-exchange capacity of soils, L. C. OLSON and R. H. BRAY. (Ill. Expt. Sta.). (*Soil Sci.*, 45 (1938), No. 6, pp. 483-496).—In the Illinois soils studied, the organic matter ranged from approximately 13,500 to 105,000 lb. per acre, and the organic base-exchange capacity varied from 0.6 to 16.3 milligram equivalents, constituting from 6.8 to 43.4 percent of the total base-exchange capacity of the soils. The end point in the destruction of the organic base-exchange capacity was reached by using a single 40-cc. treatment with 15 percent H_2O_2 . In the sample of peat studied, one treatment with 40 cc. of 22.5 percent H_2O_2 was necessary to reach the end point

in the destruction of the organic base-exchange capacity. Manganese dioxide interfered in acid, neutral, and alkaline suspensions. Manganous salts interfered in alkaline media. Calcium carbonate also made the complete destruction of organic base-exchange capacity difficult. "It is recommended that, in studying soils similar in nature to the soils included in the present work (the peat excepted), one treatment with 40 cc. of 15 percent peroxide be used in the method described. This recommendation is based on the fact that although weaker concentrations of H_2O_2 gave fair results, more peroxide should probably be used in routine work as a matter of precaution. This amount should be sufficient to take care of the likely variations in the upland prairie and timber types. With unknown soils, two or more concentrations or amounts of peroxide should be used in preliminary studies to determine the amount needed for decomposition."

Effect of organic matter on the water-holding capacity and the wilting point of mineral soils, G. J. BOUVOUCOS. (Mich. Expt. Sta.). (*Soil Sci.*, 47 (1939), No. 5, pp. 377-383).—The author shows that a high percentage of organic matter markedly increases the available water capacity of light soils and to a lesser degree than that of heavier soils. This relation held good whether the percentages were based on weight or on volume. Various organic materials and several soil types were used. The data given indicate that the wilting percentage was also increased by added organic matter but rose less rapidly in proportion to percentage of organic matter than did the water retention.

The geographical distribution of soil black pigment, W. S. GILLAM. (Nebr. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 5, pp. 371-387, figs. 10).—The author reports a study of the relation of humus content and soil pigmentation to temperature and precipitation conditions, reaching the following among other conclusions:

"Soils having a relatively high organic matter content do not necessarily have the highest pigment content, nor are they always the darkest in color. The second 6 in. of all samples studied were lower than the top 6 in. in relative pigment content. The relative humus color of the soil extract is proportional to the relative pigment content.

"In regions of approximately equal rainfall, a sigmoid is obtained when organic matter content or relative humus content is plotted against mean annual temperature. Equal differences in precipitation influence the relative pigment, organic matter, and humus contents of the soil more in eastern Nebraska than in western Nebraska. Generally speaking, it can be said that for every fall of 18° F. (10° C.) in mean annual temperature along the two isohyetal lines studied the average soil organic matter and humus contents are approximately doubled, the relative pigment content of the soil is increased [from] two to six times, and the relative humus color is increased [from] two to three times. Equal differences in mean annual temperature have a greater effect on the relative pigment, organic matter, and humus contents of the soil in the area of greater precipitation. With increasing precipitation along an isothermal line the average soil organic matter, relative humus content, and relative pigment content increase, the graphical nature of these relationships being a curve; but the relative humus color increases linearly. With increasing temperature along the isohyets, a linear decrease of relative pigment content and relative humus color was noted.

"The relative pigment content and relative humus color of soil or of sand cultures were not appreciably increased by the addition of organic materials and subsequent decomposition over a period of 62 weeks. Of all soil groups studied, the relative humus content was highest in the podsol sample, followed in order by the gray-brown forest soils, the red and yellow soils, the chernozem

samples, and finally the laterite. The relative pigment content and humus color, excluding the surface few inches of the podsol, were greatest for the chernozem soils, followed by the gray-brown forest soils, the laterite, and red and yellow soils. The laterite and red and yellow samples were fairly high in humus content but low in relative pigment content."

Factors influencing the occurrence of *Azotobacter* in Iowa soils, W. P. MARTIN and P. E. BROWN. (Iowa Expt. Sta.). (*Soil Sci.*, 45 (1938), No. 6, pp. 455-466, figs. 2).—A study of the growth of *Azotobacter* in Clinton and Grundy silt loams showed that an addition of lime to these soils was essential for the prolonged growth of the bacteria and that sufficient to raise the pH to near neutrality was all that was necessary to keep the bacteria active for at least 9 mo. No individual treatment other than lime was essential for the growth of the bacteria in these soils. Except for oat straw, no treatment other than lime, regardless of combination, seemed to have any influence. There was some evidence when lime was present, however, that other treatments may aid the growth of the bacteria, particularly the oat-straw treatment of Clinton silt loam.

It was found that at the same pH, Grundy silt loam presented a better medium for the growth and activity of the *Azotobacter* than did Clinton silt loam. This difference was attributed in part to the higher organic matter content of Grundy silt loam. The limiting pH value for the growth of the *Azotobacter* in these soils was shown to be about 6.0, but it is pointed out that "the actual limiting value for the different types undoubtedly varied with the general soil conditions."

Factors influencing the rate of decomposition of different types of plant tissue in soil, and the effect of the products on plant growth, M. F. SPAULDING and W. S. EISENMENGER. (Mass. Expt. Sta.) (*Soil Sci.*, 45 (1938), No. 6, pp. 427-445).—The average proportion of nitrogen was found greater in the dicotyledonous than in the monocotyledonous group, ranging in the former from 0.67 to 4.48 percent and in the latter from 0.53 to 2.54 percent. The content of pentosans ranged in the dicotyledons from 5 to 23 percent and in the monocotyledons from 12 to 27 percent. As the nitrogenous content decreased, the content of pentosans increased. The proportion of carbon was highest in the monocotyledonous group, ranging from 42 to 50 percent. In the dicotyledonous group it ranged from 36 to 48 percent, increasing with the content of pentosans.

As the proportion of carbon and pentosans decreased, the rate of decomposition (as shown by the amounts of ammonia and nitrates formed, and by the increased plant growth) increased. The structure of plants and their content of lignin and pentosans (which resist both grinding and decomposition) were also factors in the rate of decomposition. Plants of the dicotyledonous group were more easily ground than plants of the monocotyledonous group and were less resistant to decomposition. If the ratio of nitrogen to carbon is no more than 1:25-30 the plants decompose easily, but if the ratio is wider the incorporation of natural fertilizers in the soil results in a depression of the nitrates.

Maintaining soil fertility in south Jersey, A. W. BLAIR (*New Jersey Stat. (v. 383 (1939), pp. 441)*).—This is a popular discussion of the needs of the soils of the area named, which is for the most part well drained and in some need of organic matter and lime. For truck crops from 800 to 2,000 lb. per acre of fertilizers containing from 4 to 6 percent nitrogen, from 6 to 12 phosphoric anhydride, and from 4 to 10 percent potassium may be profitably utilized.

Effect of organic materials and fertilizer treatments upon the soluble nutrients in soils, R. E. STEPHENSON. (Oreg. Expt. Sta.). (*Soil Sci.*, 45 (1938), No. 6, pp. 467-475).—The author determined water-soluble plant nutrients in such organic matter as ground grass clippings, alfalfa hay, and wheat straw

before and after their decomposition in soils. He determined also the percentages of these nutrients fixed in water-insoluble form in the soil during the decomposition.

Micro-organisms appeared to play a considerable part in the absorption not only of nitrates but of potassium and calcium as well. "The liberation of nutrients depends largely upon biological processes and especially upon the solvent effect of the strong acids such as nitric acid. The concentration of cation solutes tends, in general, to follow the abundance of nitrates in the soils studied. The weak carbonic acid does not appear to cause much solvent action, particularly in acid soils. In neutral or alkaline soils the effect of carbonic acid is probably of greater significance. The greatest quantity of water-soluble nutrients is found in the surface soil, where organic matter is most abundant and where biological processes are most active."

Fertilizer experiments simplified (*Puerto Rico Col. Sta. Rpt. 1933, pp. 32, 33*).—A simplified system of fertilizer experiments is briefly reported upon by B. Capó.

The triple-analysis method of testing soil fertility and probable crop reaction to fertilization, H. LUNDEGÅRDH (*Soil Sci., 45 (1933), No. 6, pp. 447-454*).—The full test involves three complete analyses as follows: Analysis of the green leaves of the crop, collected before flowering; analysis of the surface soil (citric acid extract of a dry sample taken at a depth of about 15 cm.); and analysis of the subsoil (citric acid extract of a sample taken just below the upper limit of the subsurface layer). The subsoil sample may be omitted in many tests. The analysis comprises determination of H, K, Na, Ca, Mg, Mn, Fe, Cu spectrographically, and PO₄ by colorimetry. Nitrogen nutrition is not included in the test.

Rapid soil tests for estimating the fertility needs of Missouri soils, L. D. BAYER and F. H. BRUNER (*Missouri Sta. Bul. 404 (1939), pp. 16*).—As a result of an experimental study here reported upon, the authors found that no rapid soil test is universally applicable to all soil or soil conditions. Each test should be carefully investigated in relation to the soils of a given State or region. Rapid soil tests may give misleading results in the hands of those unqualified to interpret them. A standardization of sampling technic is necessary to obtain representative samples of the soils in question. Soil testing in the field, with the exception of the simpler and better known methods, is subject to considerable uncertainty. This is particularly true of those tests used as a basis for making precise recommendations as to the kind and quantity of fertilizer to apply. The authors believe that the use of the same extracting solution for the determination of all nutrients is less reliable than the use of a solution specifically designed for the extraction of each nutrient to be determined. Many of the rapid tests studied were found not to be wholly specific for the plant nutrient to be determined, and were therefore considered liable to disturbing effects of other ions present in the soil tested.

Where comparisons with data from experiment field plats are available, properly interpreted soil tests may be of great value in connection with fertility recommendations. When rapid soil tests have been more completely developed for different soil areas, their use on subsoil samples as well as samples of the surface soil, particularly in relation to the growth and treatment of deep rooted crops, should give valuable information.

The use of chemical data in the prognosis of phosphate deficiency in soils, J. S. BURN and H. F. MURPHY (*Hilgardia [California Sta.], 12 (1939), No. 5, pp. 323-340, figs. 2*).—The authors find that the causes of failure to obtain correlations between plant growth and the acid-extractable phosphate of soils

are partly inherent and partly technical. The roles of adsorption complexes, hydrogels, and acid buffers, as affecting the analytical figures obtained by acid extraction of soils, are outlined. It is pointed out that the specific "acidity effect" of reagents cannot be measured in soils containing substantial amounts of adsorbing colloids if the anion of the reagent is itself adsorbed by the soil. The chemical determinations found necessary in the prognosis of phosphate deficiency are stated. A critical analysis of the quantitative effects of the calcium ion and kaolinite in determining the phosphate solubility of a type soil is presented. Hydrogen-ion concentration, phosphate concentration, present degree of saturation, and adsorption capacity of the adsorbing complex are held to determine the removal of acid-dissolved phosphate both in vitro and in the field. Chemical data on 14 soils are analyzed in the light of the findings stated to illustrate how the physiological supplying power of the soil could be deduced from the data.

Reaction between ammonia and soils, A. N. PURI and A. G. ASGHAR (*Soil Sci.*, 45 (1938), No. 6, pp. 477-481, figs. 6).—The reaction of ammonia with soils containing various percentages of exchangeable bases as well as with an ordinary buffer solution was studied. The percentage of ammonia retained by the soils was found to be a function of the pH value and to represent the residual portion of the titration curves when the soil is partly neutralized with another base. There was no evidence of any retention by adsorption.

Potash availability studies in Pennsylvania orchard soils, E. C. DUNKLE, F. G. MEERLE, and R. D. ANTHONY. (Pa. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 5, pp. 438-458, figs. 4).—An analysis of soil and leaf samples from 47 orchards in various parts of Pennsylvania led to the conclusion that the surface soils were definitely higher than subsoils in replaceable potassium, and loss of top soil by erosion is a factor in increasing the potassium need. Certain soil series were found to contain more replaceable potassium than others. A few were notably low. The quantity of replaceable potassium is related to the organic matter content of the soil. The rapid method for determining replaceable potassium compares favorably with the quantitative cobalt-nitrite method and is satisfactory for determining the general level of soil potassium. Leaf analyses did not correlate with the replaceable soil potassium, but in some cases gave indications of the effects of potassium application which could not be detected by exchange analyses.

Influence of exchangeable cations on the availability of phosphate in soils, S. RAVIKOVITCH (*Soil Sci.*, 47 (1939), No. 5, pp. 357-366, figs. 2).—The greatest availability was observed when the PO_4 was adsorbed by the Ca soil. The combination of the soil complex with the PO_4 and exchangeable calcium proved to be very unstable, breaking down under the action of very weak acids. The availability of the PO_4 adsorbed by the H complex was low, and its liberation was associated with the partial destruction of the complex. The introduction of Ca into the H complex containing PO_4 in an adsorbed state increased the stability of the complex and decreased the degree of PO_4 liberation. The effectiveness of the various exchangeable cations in liberation of the adsorbed PO_4 was in the order $\text{Na} > \text{K} > \text{NH}_4 > \text{H} > \text{Mg} > \text{Ca}$. These cations, according to their effectiveness in PO_4 adsorption, were arranged in the reverse order. The contact of mineral and organic H complexes with $\text{Ca}_3(\text{PO}_4)_2$ dissolved the salt. The dissolved phosphate was in part adsorbed by the mineral complex, but it was not retained in any appreciable quantity by the organic complex.

A study of a correlation of chemically available phosphorus with crop yields, A. C. RICHIE and J. W. WHITE. (Pa. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 5, pp. 431-437).—Truog's method (E. S. R., 64, p. 212) having been used for the determinations of chemical availability, the authors

found no correlation of available phosphorus with crop yields in the comparison of plats receiving various carriers of phosphorus, such as superphosphate, rock phosphate, basic slag, and bonemeal. Plats receiving double or triple quantities of superphosphate showed only small increases in the available phosphorus extracted. The available phosphorus of rock phosphate-treated plats was directly proportional to the amount applied, but it was many times higher than that of plats receiving superphosphate in equivalent quantities. Truog's reagent dissolved considerably more phosphorus from soils treated with rock phosphate than is easily available to the plant as measured by crop yields. The same condition occurred with bonemeal treatments but to a lesser degree.

"The available phosphorus showed an excellent correlation with crop yields on one tier of the Jordan soil fertility plats. The only exceptions were the few plats receiving either bonemeal or manure. If these plats were omitted in the calculation, the coefficient of correlation was 0.91. This high correlation is due to the fact that the phosphorus carrier was always the same, namely, superphosphate, and that these plats are approaching a phosphorus equilibrium after more than 50 yr. of existence."

The rôle of kaolinite in phosphate fixation, H. F. MURPHY (*Hilgardia* [California Sta.], 12 (1939), No. 5, pp. 341-382, figs. 8).—Soils with a kaolinitic type of clay were found to have a high capacity to fix soluble phosphates, as shown by both chemical and greenhouse experiments, in accord with field results. Phosphate fixation by the various iron systems alone is not considered sufficient to account for all of the properties that these soils show with respect to phosphate availability. Kaolinite ground to colloidal dimensions has a high phosphate-fixing capacity greatest at acid reactions, which indicates that the H_2PO_4 ion is the most favored phosphate ion for the reaction. An increase in base-exchange capacity accompanies the increase in phosphate fixed. Greenhouse experiments show that the availability of the phosphate in "kaolinite phosphate" is directly proportional to the degree of phosphate saturation. This is taken to indicate that a light phosphate fertilizer application would be ineffective on soils containing a kaolinitic clay. Even a very low percentage of kaolinite, if in a colloidal condition in a soil, tied up phosphate and made it unavailable for plants. Greenhouse and laboratory data concurred in indicating that bentonite fixed much less phosphate in a nonavailable form than did colloidal kaolinite.

A foliar diagnosis study of the influence of calcium from two sources, lime and superphosphate, W. THOMAS and W. B. MAOK. (Pa. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 9, pp. 685-693, figs. 3).—The effects of calcium from lime and from superphosphate were similar, resulting in increased absorption of native soil nitrogen and depressed absorption of native soil potassium as well as of added potassium, with concomitant increases in the absorption of calcium and magnesium.

"Calcium from both sources reduced the intensity of nutrition with respect to nitrogen, phosphoric acid, and potash ($\text{N} + \text{P}_2\text{O}_5 + \text{K}_2\text{O}$) and also lowered the K_2O in the NPK unit from 20 to 8 (in round numbers). Liming resulted in an increase in the nitrogen of the NPK unit and in a relatively great increase in the P_2O_5 made at the expense, principally, of the potash. The yields of grain from the different treatments are classed in relation to the intensities of nutrition and the composition of the mean NPK units. The lowest yields of grain are associated not with treatments (check, dried blood) having the lowest intensity of nutrition but with the lowest P_2O_5 in the NPK unit. A reduction of 58 percent in P_2O_5 in the NPK unit of the check as compared with P brought about a reduction in yield of grain not offset by the accompanying increase of

142 percent in K_2O in the NPK unit which occurred at the expense, principally, of P_2O_5 ."

Sufficiency of atmospheric sulfur for maximum crop yields, F. J. ALWAY, A. W. MARSH, and W. J. METELEY. (Minn. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 2 (1937), pp. 229-238, figs. 4).—The annual fall of sulfur in rain, snow, and dust in Minnesota has been found to vary from a maximum of more than 100 lb. an acre in Minneapolis to a minimum of less than 5 lb. in a sulfur-deficient area in the northern part of the State. Where the collection of the water for analysis was made in vessels entirely or partly of a metal subject to attack by sulfur dioxide erroneously high values were found, the sulfates formed between rains on the interior metal surfaces being washed down into the collector and appearing as though brought down in the precipitation. An appreciable amount of sulfur dioxide was found in the atmosphere even in the most remote and most sulfur-deficient areas of the State. Its relative concentration was determined by absorption on a surface coated with lead peroxide. The amount absorbed in the course of 12 mo. per acre of exposed surface varied from more than 400 lb. of sulfur in Minneapolis to less than 5 lb. near the headwaters of the Mississippi River. The absorption of sulfur dioxide by soils was found to parallel roughly its absorption by lead peroxide, but likely to furnish less sulfur to crops than that brought down by the precipitation. It is computed that the sulfur dioxide absorbed by the leaf tissue of plants in sulfur-deficient areas will be of even much less significance than that absorbed by the soil.

Registration, labeling, and inspection of commercial fertilizers, 1938, M. F. MILLER, L. D. HATCH, and E. W. COWAN (*Missouri Sta. Bul.* 403 (1939), pp. 45).—The usual analytical data are here given for the 1938 season, with some related information. The total tonnage of mixed fertilizers increased from 1932 to 1936 and then fell off somewhat. The percentage of high grade mixtures has increased from 1932 through 1938.

Analyses of commercial fertilizers, fertilizer supplies, and home mixtures for 1938, C. S. CATHCART (*New Jersey Stat. Bul.* 657 (1939), pp. 35).—Tabulations and summaries of the results of the greater part of the 1938 inspection analyses are here given, the remainder in the bulletin noted below.

Analyses of commercial fertilizers and ground bone; analyses of agricultural lime, 1938, C. S. CATHCART (*New Jersey Stat. Bul.* 662 (1939), pp. 15).—This bulletin presents the data not included in the report noted above, together with a discussion of the year's fertilizer inspection work as a whole.

AGRICULTURAL BOTANY

[Abstracts of papers presented at Colorado State College of Education, 1938] (*Jour. Colo.-Wyo. Acad. Sci.*, 2 (1939), No. 5, pp. 29, 30, 31, 33, 34, 35, 36).—Abstracts of the following papers of interest to botany are included: Comparative Effects on Primordial Tissue of X-Radiation and Treatment With Certain Growth-Promoting Substances, by V. C. Irvine; Floral Development of Certain Species as Influenced by X-Radiation of Buds, by E. L. Johnson; Further Studies of High Frequency Irradiation Upon *Hordeum vulgare*, by C. R. Bitter; New Facts About Old [Alfalfa] Seeds, by A. M. Lute, and A Note on the Composition of Russian Thistle, by H. W. Reuszer and R. W. Monk (both Colo. State Col.); Life Forms of Plants in Colorado Sand Hills, by F. Ramaley; Is the Genus a Natural Category? by M. T. James (Colo. State Col.); Genesis of Earth Forms and Its Effect Upon Some Southwestern Delphiniums, by J. Ewan; and Rushing in Where Scientists Fear to Tread (New Avenues in Systematic Botany), by M. W. Pesman.

Kansas botanical notes, 1937, F. C. GATES. (Kans. State Col.). (*Kans. Acad. Sci. Trans.*, 41 (1938), pp. 97, 98).—This consists largely of seasonal notes, but includes brief references to a survey said to indicate red cedar, Chinese elm, and Osage orange to be the best trees suited for the semiarid conditions of western Kansas, and to a natural cross between Atlas sorgo and Johnson grass in which many fertile seeds were produced.

Woody plants, native and naturalized in Kansas, F. C. GATES. (Kans. State Col.). (*Kans. Acad. Sci. Trans.*, 41 (1938), pp. 99-118, figs. 208).—This check list is presented to replace *Trees in Kansas*,² but without descriptions, keys, or drawings. The 225 species, varieties, and hybrids included are grouped under 45 families. Of this number, the native flora is said to contain 107 kinds of trees, 50 of shrubs, and 20 of lianas. Indexes to families, genera, and common names, and 208 distributional maps are included.

Ecology in agriculture, H. C. HANSON. (N. Dak. Expt. Sta.).—(*Ecology*, 20 (1939), No. 2, pp. 111-117).—The author describes a few examples to illustrate the need for ecologists to conduct research in crop plants, the importance of climax or near-climax stages, and the special contribution of ecology to ferret out the relationships of man with his agricultural environment. "Permanent agriculture must be in adjustment with the environment."

The interrelation of soils and plant, animal, and human nutrition, E. C. AUCHTER. (U. S. D. A.). (*Science*, 89 (1939), No. 2315, pp. 421-427).—In this address the author outlines the cycle of energy exchange through soil, plant, and animal, discussing the mineral requirements of plants and animals, some soil deficiencies resulting in nutritional disorders of plants and animals, the production and use of energy, factors affecting the value of plants as food, and suggested investigations and objectives.

The individualistic concept of the plant association, H. A. GLEASON (*Amer. Midland Nat.*, 21 (1939), No. 1, pp. 92-110).—The author defines and discusses the individualistic concept of plant associations and compares it with other theories.

The unistratal concept of plant communities (the unions), T. LIPPMAN (*Amer. Midland Nat.*, 21 (1939), No. 1, pp. 111-145, figs. 11).—A review and discussion of this ecological concept, with a three-page bibliography.

Plant associations on land, H. S. CONARD (*Amer. Midland Nat.*, 21 (1939), No. 1, pp. 1-27).—This is a critical review of published works and concepts (with about four pages of references) on plant sociology, the goals of which are stated to be "an understanding of the order of nature" and "directions for the wisest use of land."

The biome, J. R. CARPENTER (*Amer. Midland Nat.*, 21 (1939), No. 1, pp. 75-91).—A critical review (with over three pages of references) of the ecological concept of the biome.

The climax and its complexities, S. A. CAIN. (Univ. Tenn.). (*Amer. Midland Nat.*, 21 (1939), No. 1, pp. 146-181).—This is a comprehensive, analytical review of climax vegetation, with about five pages of references.

Pollen analysis of a bog in northern Idaho, H. P. HANSEN (*Amer. Jour. Bot.*, 26 (1939), No. 4, pp. 225-228, fig. 1).—Five ecologic periods were indicated by this study, and the interpreted climatic sequence in this region apparently correlates closely with that farther south near Spokane, Wash., and to some extent with that in the Puget Sound region.

Marsh gas in the ecology of some peat-bogs, H. A. ALLARD. (U. S. D. A.). (*Science*, 89 (1939), No. 2319, pp. 533-535).—This is a discussion of the environal

² Kans. State Bd. Agr. [Quart.] Rpt., 47 (1928), No. 186-A, pp. 372, figs. 210.

relations of peat bogs, with special reference to a bog near Oxford, Mass., in which methane was observed to collect beneath the root layers of the sedge mat as a zone of bubbles. The plant life here would seem to substantiate the assumption of a relatively inactive physiological behavior of this gas. It may at least be an important factor under some conditions in helping to create a low oxygen atmosphere in the water and air surrounding the roots of a group of normal associations of these areas which are highly tolerant of such conditions.

The ecological problem of mycotrophy, L. G. ROMELL (*Ecology*, 20 (1939), No. 2, pp. 163-167, fig. 1).—The author reviews published data (17 references) on the mechanism of mycotrophy, concluding for conifers that, considering all the known facts, there seems to be scarcely an escape from assuming that the associated obligate mycorrhizal fungi are not saprophytes decomposing soil organic matter but are energetically parasites on their hosts. A root mass presenting the same surface and omnipresence would seem to require a much greater expenditure of assimilates. "If this is so, a sufficient root system would be more of a parasite on the tree than the mycorrhizal fungi are, and it is easy to realize how the mycorrhiza can be a 'beneficial disease.'" Reference is also made to the orchid mycorrhizas and to the ecology of the chlorophyll-free *Monotropas*.

Legume nodule development in relation to available energy supply, F. E. ALLISON and C. A. LUDWIG. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 2, pp. 149-158).—Considering recently published data and interpretations (19 references, including the authors'), the following conclusions are drawn: Although there are many special factors independently influencing nodule behavior, the amount of available carbohydrates reaching the roots is normally the chief influence affecting nodule formation under variations in photosynthesis and in the presence of either free or varying amounts of combined nitrogen. When there is no N assimilation, N is present in minimum and carbohydrate is not the controlling factor. The inhibiting effect on nodulation of large additions of fixed N is due chiefly to the resultant decrease in available carbohydrates. Growth of roots relative to tops is also lowered for the same reason. A small change in sugar concentration in the root sap may produce a change in nodule mass several times as large during a considerable growth period because the weight of the nodules, like the total dry weight of the plant, tends to increase exponentially. The carbohydrate supply theory is believed to account for varying degrees of nodulation under different growth conditions more simply, directly, and adequately than the subsequently proposed carbohydrate-nitrogen relation theory.

A relationship between pollination and nodulation of the Leguminosae, J. K. WILSON. (Cornell Univ.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 2, pp. 159-170).—The evidence presented indicates that a relationship may exist between pollination and nodulation in legume species. Those that are completely self-pollinating may not bear nodules, or when they do the number of *Rhizobium* strains with which they will symbiose is small. When cross-pollination is obligatory the number of strains with which the plant will symbiose is comparatively large. The *Rhizobium* strains symbiosing with self-pollinating species appear predominantly monotrichic, while those symbiosing with cross-pollinating species appear predominantly multitrichic, though both morphological types may be found symbiosing with the latter plants. Such relationships apparently do not correlate with the order, tribe, genus, or species of the plants, except as they may be influenced by pollination. If this suggested relationship proves valid it will place symbiosis on a heritable basis and in the same category with the inheritance of resistance to certain plant diseases.

Cell polarity and the differentiation of root hairs, E. W. SINNOTT and R. BLOCH (*Natl. Acad. Sci. Proc.*, 25 (1939), No. 5, pp. 248-252, fig. 1).—Using a technic recently described by Sinnott,^{*} root hair development was studied in *Phleum pratense*, *Poa trivialis*, *Chloris gayana*, and *Sporobolus cryptandrus*, and is described. Pronounced and regular differences between cells in their capacity to form root hairs, and between related genera in the time and character of root-hair differentiation, were found and should be taken into account in studies dealing with the factors responsible for root-hair development. Whatever the causes, it seems clear from the data presented that in related grass genera there are markedly different types of root-hair determination—in one, differentiation is early and strongly apical; in another, late and but slightly or not at all apical.

A developmental analysis of the relation between cell size and fruit size in cucurbits, E. W. SINNOTT (*Amer. Jour. Bot.*, 26 (1939), No. 4, pp. 179-189, figs. 14).—In 12 races of 4 cucurbit genera the cell diameter was measured in a series of tissues from the central region of the ovary to the outside and at many developmental stages from very small ovary primordia to mature fruit. In each tissue growth was found to occur at first chiefly by cell multiplication, but after attainment of a specific cell size division ceased and further growth was by cell expansion. The innermost tissues, as compared with successive outer ones, showed more rapid increase in cell size during the cell-division period, earlier cessation of division, and greater cell size at that time. In *Cucurbita pepo*, large-fruited as compared with small-fruited races typically showed no difference in cell size during early development, a longer period of cell division due to less rapid increase in cell size, greater cell size at the last division, a longer interval between cessation of division in successive tissues, and a greater cell expansion after cessation of cell division. Specific developmental differences between *Cucurbita* and the other 3 genera studied (*Lagunaria*, *Cucumis*, and *Citrullus*) are described, and possible mechanisms responsible for the differences in cell division and cell expansion among the various tissues in the various races are discussed. The problem of the size relations of cell and organ is noted as part of the more general problem of the factors determining growth and differentiation, and the first step in solving this problem is through descriptive analyses in quantitative terms.

Anatomy of the hypocotyl and roots of *Daucus carota*, L. HAVIS. (Ohio Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 8, pp. 557-564, pls. 7, fig. 1).—The carrot epicotyl is enclosed in a short cotyledonary tube, and lateral roots arise both from the lower hypocotyl and the primary root. The seedling transition zone is in the upper part of the hypocotyl and relatively short. Both primary and lateral roots are diarch. The edible part of the carrot is largely hypocotyl, though the upper taproot is also often enlarged, the relative amounts depending on the variety. At first the cambium and pericycle are active, and as the carrot develops further the xylem and phloem become meristematic, with considerable enlargement especially of the xylem parenchyma. The cortex is shed when the fleshy root and hypocotyl are 3-5 mm. in diameter, the cork cambium then being derived from the pericycle. The mature structure is composed largely of xylem, phloem, and pericyclic parenchyma. Lateral roots originate in the pericycle and at an angle of $\pm 45^\circ$ with the primary xylem cylinder, and also often at the periphery of the pericycle during early secondary growth and likewise after the cortex of the hypocotyl has disappeared. The latter type arises near the place of emergence of the endogenous lateral root.

^{*} *Natl. Acad. Sci. Proc.*, 25 (1939), No. 2, pp. 55-58.

A correlation between sulphydryl, mitosis, and cell growth in length in roots of *Phaseolus vulgaris*, F. S. HAMMETT and S. S. CHAPMAN (*Growth*, 2 (1938), No. 4, pp. 297-302).—Quantitative analyses for sulphydryl (SH) of root sections of sprouting beans established a positive correlation between proliferation activity and SH concentration, and a negative one between SH concentration and root growth by cell elongation. The order of increasing SH amount was mid-section, contiguous meristem, and terminal meristem. It is concluded that this finding agrees with the postulate that SH is specifically associated with cell increase in number as distinct from cell increase in size.

Diurnal cycle of heat resistance in plants, H. H. LAUDE. (Kans. Expt. Sta.). (*Science*, 89 (1939), No. 2320, pp. 556, 557).—This daily cycle was discovered in several field-crop plants, including corn, wheat, barley, sorghum, and alfalfa. The maximum resistance was attained about midday and continued during the afternoon, while the minimum prevailed early in the morning. The heat resistance increased on exposure to electric light and decreased in darkness. The degree of temperature required to distinguish differences in heat resistance depended on the species and the condition of the plants. Specific examples of the experimental results and suggested explanations of the phenomenon are given.

Bergey's manual of determinative bacteriology: A key for the identification of organisms of the class Schizomycetes, D. H. BERGEY, R. S. BREED, E. G. D. MURRAY, A. P. HITCHENS, ET AL. (Baltimore: Williams & Wilkins Co., 1939, 5. ed., pp. XI+1032).—Whereas the first edition included descriptions of 832 bacterial species with a reference to the original place of publication of 1,577 descriptions, this edition contains descriptions of 1,335 species with a reference to the original place of publication of 5,600 descriptions. These figures graphically indicate the development occurring since 1923. The chief changes from the fourth edition (E. S. R., 71, p. 28) occur in the Eubacteriales, where the number of recognized families has been increased from 3 to 12. The genus *Bacterium* has been retained to include species whose relationships are obscure. Nine new generic names are used: *Veillonella*, *Malleomyces*, *Noguchia*, *Microbacterium*, *Fusobacterium*, *Proactinomyces*, *Caulobacter*, *Pasteuria*, and *Blastocaulis*—the last three in the new order Caulobacteriales. It will be noted that in spite of the extensive rearrangement of genera and the use of nine new generic names, few new binomials have been formed, and no trinomials are used. Nearly all the species descriptions have been checked against the original descriptions, and the keys have been improved. See also a note by Burkholder (E. S. R., 80, p. 781).

After suggestions for use of the manual in classifying unknown organisms, there are the following general sections: Historical survey of classifications of bacteria, with emphasis on outlines proposed since 1923 (pp. 4-38), and rules of nomenclature (pp. 51-68), both by R. S. Breed (N. Y. State Expt. Sta.); and how bacteria are named and identified, by R. E. Buchanan (pp. 39-50) (Iowa State Col.).

Cytological appearances in a spore-forming bacillus: Evidence of meiosis, L. A. ALLEN, J. C. APPLEBY, and J. WOLF (*Zentbl. Bakt. [etc.]*, 2. Abt., 100 (1939), No. 1-3, pp. 3-16, pls. 2, figs. 5).—A bacillus isolated from grass, observed by a vital-staining technic, exhibited a cycle of changes in morphology and cytology as the culture progressed from extreme youth to old age, and these phenomena are discussed in detail and illustrated. Spores are said to be formed in several ways, one method involving well marked nuclear reorganization within the cell. Evidence of the presence of chromosomes and of structures suggestive of meiosis are reported to have been clearly seen preceding the

above type of spore formation, during germination of some of the liberated spores sown on fresh media, and in some of the liberated spores in the so-called "resting" condition.

Growth of microorganisms in shake cultures under increased oxygen and carbon dioxide tensions. J. W. WILLIAMS (*Growth*, 3 (1939), No. 1, pp. 21-33, fig. 1).—The changes, in general of the same order, are discussed without reference to individual organisms (*Escherichia*, *Pseudomonas*, *Staphylococcus*, *Protus*, *Bacillus*, and *Salmonella* species used). The depth of the upper limit of spectral growth (subsurface growth bands under increased gas tensions) was found to depend on O_2 and CO_2 tensions (pressure chambers used), time and temperature of growth and its initiation, number of organisms planted, percentage of nutrient, growth inhibitory factors, and reducing and oxidizing agents. Width and consistency of spectral growth depended on time of growth, percentage of nutrient, $O_2 : CO_2$ ratio, growth inhibitory factors, reducing and oxidizing agents, number of organisms planted, temperature of growth and its initiation, and substances encouraging anaerobic growth. Within limits, O_2 counteracted the inhibiting effects of CO_2 . The Eh and pH of the medium above the spectrum were similar to controls, but decrease usually occurred in and below the growth to a varying extent and depth with certain organisms. Changes in bromothymol and methylene blue in media were what would be expected from Eh and pH readings. All organisms studied were able to concentrate methylene blue to a variable extent in lines and bands in and directly above their spectrums, and some were able to change the blue to its various azures. Explanation of the various changes is suggested, and evidence is presented pointing to an O_2 diffusion gradient in the media studied. Most appearances produced with inanimate precipitates in gels were produced by bacterial growths in shake cultures.

It is believed that the great possibilities presented by growing microorganisms under increased gas tensions should win this method a place with anaerobic and aerobic methods of growth in bacteriological studies.

Optimum solutions as physiological reference standards in estimating nitrogen utilization by *Aspergillus niger*. R. A. STEINBERG and J. D. BOWLING. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 10, pp. 717-732, figs. 3).—Yield curves with graduated amounts of nitrogen were obtained with *A. niger* grown in optimum nutrient solutions for 4 days at 35° C. Of the duplicate cultures, 45 percent agreed within ± 1 percent, 68 percent within ± 2 , 82 percent within ± 3 , and 95 percent within ± 5 percent. On repetition, yields could be verified within ± 5 percent. Growth with NH_4NO_3 was studied at three carbohydrate-nutrition levels and compared to that obtained with NH_4Cl and with $NaNO_3$. The growth and total N curves obtained with 2.5, 5, and 7.5 percent of sucrose were proportional and identical in form when superimposed, and other results for these solutions were also practically identical. At intermediate N concentrations, NH_4Cl gave lower and $NaNO_3$ still lower yields than did NH_4NO_3 . Total N in the mycelial felts grown with NH_4NO_3 increased linearly with increasing N concentration. Values for total N in the felts could be computed within the limits of accuracy for the chemical determinations. It is assumed that the fungus invariably contained 2 percent of protoplasmic N, and that the balance of the N supplied was partitioned between the organism and the solution similarly to the distribution of a dissolved substance between two immiscible solvents. The values of yield curves with NH_4NO_3 could not be duplicated by computation with the Mitscherlich growth equation.

Influence of bile and bile salts on *Aërobacter aërogenes*. J. H. FULLER. (Mass. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 38 (1938), No. 4, pp. 507-

510).—The results of culturing 30 strains of *A. aerogenes* in media containing bile or bile salts were in favor of the stability of the culture reactions of pure established culture so far as the influence of these substances was concerned, and no evidence that this organism is a derivative of *Escherichia coli* was obtained.

Isoplanogametes in Blastocladia, E. A. BESSEY (*Mycologia*, 31 (1939), No. 3, pp. 303–309).—This type of sexual union observed in *Blastocladia* is compared with that by heteroplanogametes in the closely related fungus *Allomyces*.

Some *Pezizula* species and their conidial stages, J. W. GROVES (*Canad. Jour. Res.*, 17 (1939), No. 5, Sect. C, pp. 125–143, figs. 4).—"The following species of *Pezizula* have been cultured and the genetic connection of their conidial stages has been established: *P. carpineae* (Pers.) Tul. with the conidial stage *Cryptosporiopsis fasciculata* (Tode) Petr., *P. pruinosa* Farl. with the conidial stage *Sphaeronema prunosum* Peck, *P. corni* with the conidial stage *C. cornina* (Peck) Petr. and Syd., *P. rubi* (Lib.) Niessl with the conidial stage *Discosporiella phaeosora* (Sacc.) Petr., and *P. hamamelidis* n. sp. with the conidial stage a *Cryptosporiopsis* species. The form of the conidial spore is relatively constant in the different species, but the form of the conidial fruiting body is variable."

Growth of fungi in synthetic nutrient solutions, R. A. STEINBERG. (U. S. D. A.). (*Bot. Rev.*, 5 (1939), No. 6, pp. 327–350).—This comprehensive review (99 references) discusses the subject relative to carbon, nitrogen, mineral, and supplementary organic requirements, the protoplast-solution system, nutrient requirements for reproduction, and induction of variants with chemicals. It is pointed out that in recent years the trend has seemed to emphasize studies of accessory factors and mineral nutrition, with but little on the physiology of reproduction or on carbon requirements and little or none on enzymes of fungi. Certain suggestions and warnings concerning future investigations are given.

Root temperature effects in a nutrient solution, L. H. JONES and G. E. O'BRIEN (*Massachusetts Sta. Bul.* 355 (1939), p. 28).—A brief progress report on work with gardenia and soybean.

Further analysis of the pea test for auxin, F. W. WENT (*Bul. Torrey Bot. Club*, 66 (1939), No. 6, pp. 391–410, figs. 4).—In this study the method previously used (El. S. R., 78, p. 759) was simplified by marking the stems with a lanolin-lampblack suspension and transferring the marks, which do not dry up, to paper. The pea test curvatures, appearing when etiolated stems are split in the growing region and placed in auxin solutions, are due to differential tissue growth under the intact epidermis and the tissues bordering the wound. This is not an innate differential sensitivity, but is due to the rapid loss of sensitivity of the tissues near the wound. When auxin reaches the cells before the loss of sensitivity small pea test curvatures or none result. The author resolves the auxin effect in the pea test into a chain of two reactions—(1) the so-called preparatory reaction, which is independent of pH and can be induced by substances lacking growth activity (hemiauxins), indole compounds inducing this reaction in relatively high concentrations, and (2) the growth reaction proper, which follows (1) in time and requires a much lower auxin concentration. With these new data it is believed that a number of peculiarities can be explained. A greatly improved pea test for very low auxin concentrations is described.

Is auxin produced in roots? J. VAN OVERBEEK (*Natl. Acad. Sci. Proc.*, 25 (1939), No. 5, pp. 245–248, figs. 2).—Although under the conditions described in this preliminary report, using excised root tips of germinating peas on dextrose agar blocks, no evidence was found for auxin production, this is not taken

necessarily to mean that under natural conditions (intact roots) no production will occur. Attention is called to recent evidence by Addicott and Bonner (*E. S. R.*, 80, p. 600) that excised pea roots grown in vitro under sterile conditions in a complete medium (containing both vitamin B₁ and nicotinic acid) may be able to synthesize auxin.

Induced parthenocarp of watermelon, cucumber, and pepper, C. WONG. (Mich. State Col.). (*Science*, 89 (1939), No. 2314, pp. 417, 418).—A preliminary report on naphthaleneacetic acid-induced parthenocarp.

Properties of a new growth factor for lactic acid bacteria, E. E. SNELL and W. H. PETERSON. (Univ. Wis.). (*Jour. Biol. Chem.*, 128 (1939), No. 3, pp. XCIV, XCV).—An abstract.

The metabolism of amides in green plants.—III, The mechanism of amide synthesis, H. B. VICKERY and G. W. PUOHER. (Conn. [New Haven] Expt. Sta. et al.). (*Jour. Biol. Chem.*, 128 (1939), No. 3, pp. 703-713).—In continuation of the series (*E. S. R.*, 81, p. 186) and on the basis of a critical review (28 references), explanations that have been advanced for the formation under certain circumstances of asparagine and glutamine in plants are discussed. The Prianschnikow ammonia detoxication theory is found inadequate to account for the behavior of the amides in ammonia-rich rhubarb leaves or in tobacco leaves grown under conditions giving rise to high ammonia concentrations. It has been suggested that the Kiebs citric acid cycle theory proposed to account for carbohydrate respiration in animals might be applied to plants. This scheme of reactions provides means whereby oxaloacetic acid and α -ketoglutaric acid, the most probable precursors of asparagine and glutathione, respectively, arise from several sources. On this view the amide metabolism becomes a phase of the general respiratory activity of the tissues and undue ammonia on ammonia as a stimulant to the reaction is removed. It is shown that the amide behavior in leaf tissues cultured under various conditions agrees with this conception, the variations in the nature and rate of amide formation being explicable in terms of variations in the details of the respiratory mechanism.

Starch dissolution and amylolytic activity in leaves, H. A. SPOEHR and H. W. MILNER (*Amer. Phil. Soc. Proc.*, 81 (1939), No. 1, pp. 37-78, figs. 2).—"More precise knowledge of the conditions affecting certain enzymes in the living leaf is of importance for an understanding of the processes resulting in the accumulation and disappearance of the products of photosynthesis. For this purpose amylase deserves special consideration, because starch is the first visible product of photosynthesis and also serves as transitory reserve food material. Certain leaves are capable of undergoing starch dissolution in an atmosphere free of oxygen, although the rate of this activity under these conditions is lower than that in normal air. Starch dissolution does not occur in leaves which have been killed by means which do not destroy the enzyme. Higher concentrations of carbon dioxide exert a distinctly inhibiting effect on the rate of starch dissolution of leaves. Comparative determinations of the amylolytic activity of a number of different species of leaves have been made. These show great variation, and also considerable range in the pH of maximum activity of different species. Both starch dissolution and amylolytic activity are decidedly accelerated with the loss of water from the leaves. Also, with decreased temperatures some leaves exhibit an increased amylolytic activity and in some cases an increased rate of starch dissolution." There are 38 literature references.

The effect of zinc on the growth process, H. S. REED and J. V. BECK. (Univ. Calif.). (*Growth*, 3 (1939), No. 1, pp. 1-7, figs. 3).—Corn grown in tanks of Delhi, Calif., soil without added zinc developed deficiency signs comparable to those obtained in culture solutions of purified salts. In all three experiments reported the height and dry weight of the plants exhibited consistent differences

in favor of small amounts of Zn, while its deficiency curtailed the production of cobs and kernels more than that of stalks, leaves, and husks. The grand period of growth of the minus- and plus-Zn plants was about the same. The equations for the growth curves of the two lots of plants resembled each other, though the values of the constants representing final and half-time height were greater for the plus-Zn series.

The loss of carbon from excised rhubarb leaves during culture, H. B. VICKERY and G. W. PUCHER. (Conn. [New Haven] Expt. Sta. et al.). (*Jour. Biol. Chem.*, 128 (1939), No. 3, pp. 685-702).—Determinations of total and insoluble carbon in a series of rhubarb leaves are discussed in terms of C losses due to respiration occurring when the leaves are subjected to culture under various conditions. Respiration is shown to draw on components other than carbohydrates, even when leaves of reasonably high carbohydrate content are taken. With initial low carbohydrate content it was possible to demonstrate that an appreciable amount of C lost by respiration originated from the proteins of the leaf blade tissue. These were hydrolyzed promptly in all cases, and it is suggested that the residues remaining after oxidative deamination of the amino acids may be more or less completely oxidized subsequently. Leaf cultures in glucose solution or in water in the light had but little effect on the rate of hydrolysis of the protein except possibly to stimulate the initial phase, and, in spite of the additional carbohydrate supply to the leaves thus furnished, evidence that a part of the protein C was respired could still be obtained. Thus, even when carbohydrate is supplied to the leaves, respiration may still draw on a wide assortment of tissue components.

Speculative and highly generalized relationships of the carbohydrates, organic acids, and proteins with respiration have been recently suggested by Gregory and Sen (*El. S. R.*, 78, p. 605). With them the present results were found, in general, to agree, although no information with regard to detailed chemical mechanisms has been secured.

The effect of sterilization with calcium hypochlorite on germination of certain seeds, J. N. SPAETH and M. AFANASIEV. ([N. Y.] Cornell Expt. Sta.). (*Jour. Forestry*, 37 (1939), No. 5, pp. 371, 372).—"Although the retarding effect of calcium hypochlorite on the germination of seeds is not universal, the authors show that it not only retards the germination of certain forest tree [*Magnolia* and *Robinia* species] seeds but also greatly reduces the germination percentage."

A small hygrometer, D. E. HOWELL and R. CRAIG. (Univ. Calif.). (*Science*, 89 (1939), No. 2319, p. 544, fig. 1).—This sensitive and inexpensive hygrometer consists of the balance wheel, hairspring, and small parts of the bearing plates of a small jeweled wrist watch attached to a glass plate, with an ether- and alcohol-washed human hair as the indicator. It is said to be accurate, easily read without changing the humidity, and usable in very small spaces.

A simple mechanical thermoregulator, A. C. BRATTON (*Science*, 89 (1939), No. 2321, pp. 589, 590, fig. 1).—The apparatus described and illustrated uses the principle of controlled cooling for regulating the temperature of a bath. The advantages claimed over the usual electric types are its comparable sensitivity at lower cost, with its greater dependability and simplicity. Three types of bulb to be attached to the control head of the thermoregulator are described, with sensitivity ranging from $\pm 0.01^\circ$ to $\pm 0.003^\circ$.

Another photoelectric device for measuring leaf areas, R. E. GIBSON and C. H. GARDNER. (Purdue Univ.). (*Ind. Acad. Sci. Proc.*, 53 (1937), pp. 72, 73).—An abstract.

Vital-staining of plant cells, E. KÜSTER (*Bot. Rev.*, 5 (1939), No. 6, pp. 351-370).—This critical review (six pages of references) discusses the subject rela-

tive to cytoplasm, nucleus, plastids, chondriome, cell walls, vacuole, determining pH values of cells or their vitally stained parts, oxidation-reduction potentials, and general considerations.

GENETICS

Recent developments in our knowledge of chromosome structure and their application to genetics, T. S. PAINTER (In *Science in Progress*, edited by G. A. BAITSELL. *New Haven, Conn.: Yale Univ. Press; London: Oxford Univ. Press, 1939*, pp. 210-232, figs. 3).—Recent developments in cytogenetics, based largely on advances opened up by the salivary chromosome technic, are summarized.

Interpretation of Mendelian class frequencies, W. A. HENDRICKS, J. P. QUINN, and A. B. GODFREY. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 10, pp. 755-760).—A new chi-square table which facilitates the interpretation of Mendelian class frequencies is presented.

A graphic method for the rapid analysis of Mendelian distributions [trans. title], J. L. PEDELABORDE (*Rev. Argentina Agron.*, 6 (1939), No. 1, pp. 35-40, figs. 3; *Eng. abs.*, p. 40).—A graphic method presenting the relation of theoretical ratios to their probable errors is suggested for ready reference and rapid indication of what ratio best fits the observed data.

Genetics of chlorophyll deficiencies in red clover (*Trifolium pratense* L.), I, II, R. D. WILLIAMS (*Jour. Genet.*, 37 (1939), No. 3, pp. 441-482).—Two contributions are presented.

I. *Albinos* (pp. 441-455).—The characteristics, behavior, and linkage relations of eight simple recessive chlorophyll-deficient factors, w_1 to w_8 , inclusive, governing the formation of albino seedlings in red clover are reported. Most of these factors were shown to be genetically distinct from seven yellow lethal seedling factors noted below. Ten other white seedling types apparently due to simple recessive genes but not yet tested are noted.

II. *Yellow seedling factors* (pp. 459-482).—Seven simple recessive factors governing the production of yellow chlorophyll-deficient lethal seedlings in red clover were identified and designated y_1 to y_7 , inclusive. They were shown to be genetically different from each other and from the eight white seedling factors with which they were tested. Their characteristics, behavior, and linkage relations are described. Nine other yellow lethal chlorophyll deficiencies, also inherited on a simple Mendelian basis, were isolated.

Genetic studies with factors in the tenth chromosome in maize, M. M. and V. H. RHOADES. (U. S. D. A.). (*Genetics*, 24 (1939), No. 2, pp. 302-314, pl. 1, fig. 1).—The linkage data presented placed the gene (Rp) for resistance to rust (*Puccinia sorghi*) in the genetic map of chromosome 10, and also determined the linear order and map position of the li (linente) and d_7 (dwarf) loci. A previously undescribed character, designated sp_2 (small pollen), had a somilethal effect upon the male and female gametophytes. Pollen grains carrying sp_2 did not differ visibly from normal grains except that they were smaller, yet 96.6 percent of sp_2 grains could not compete successfully with normal pollen. Forty-four percent of sp_2 eggs were infertile and did not develop into mature kernels. Crossing over was reduced in adjacent regions when sp_2 was heterozygous. The data placed sp_2 approximately one cross-over unit to the left of R . Cytological studies at pachytene disclosed no chromosomal irregularity in $+sp_2$ plants. Other linkage data presented located another new gene l_2 (luteus) between li and g_1 .

The genetic map for chromosome 10 was extended from 32 to 84 units by the linkage data, which determined the sequence and map positions as follows:

<i>Rp</i>	<i>sp₂</i>	<i>li</i>	<i>l₆</i>	<i>o₁</i>	<i>R</i>	<i>d</i>
0	27	28	38	43	57	84

Earlier cytological observations had placed *Rp* in the distal one-fourth of the short arm of chromosome 10 (E. S. R., 73, p. 764) and the *R* locus in the distal 22 percent of the long arm (E. S. R., 71, p. 30).

Heritable characters in maize.—L. Vestigial glume, G. F. SPRAGUE. (Mo. Expt. Sta. and U. S. D. A.). (*Jour. Hered.*, 30 (1939), No. 4, pp. 143-145, figs. 3).—The series (E. S. R., 74, p. 181) is continued.

Appearing in corn from Belgian Congo, vestigial glume (*Vg vg*) was found dominant to normal. The plants are characterized on the tassels by reduction in glume size and exposure of anthers and on the cobs by reduced outer glumes and almost completely suppressed flowering glumes and paleas. Vestigial glume plants are fully viable, of normal size, and compare favorably with their *vg* sibs in yield. *Vg* belongs in the first linkage group in the suggested order *f₁-Vg-br-bm₁*. Since in certain types of canned sweet corn the whole grains are removed from the cob, often with portions of glumes adhering, introduction of *Vg* into sweet corn stocks is being attempted to eliminate this undesirable feature.

The occurrence of parthenogenetic diploids in tetraploid maize, L. F. RANDOLPH and H. E. FISCHER. (U. S. D. A. and [N. Y.] Cornell Expt. Sta.). (*Natl. Acad. Sci. Proc.*, 25 (1939), No. 4, pp. 161-164).—The parthenogenetic corn diploids in general resembled in appearance and breeding behavior the diploid stocks from which their maternal tetraploid parents were derived.

Incidence and inheritance of pollen sterility in the potato, F. A. KRANTZ, C. L. BECKER, and Z. M. FINEMAN. (Minn. Expt. Sta. and U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 8, pp. 593-601).—Studies on 2,786 individuals derived from 101 selfed lines of the potato indicated that 47.8 percent flowered and 60.9 percent of the flowering individuals set fruit. The failure of the remainder of the flowering individuals to set fruit, according to evidence from hand cross-pollinations, might have been due to environmental factors. The pollen and fruit setting for 514 individuals of 69 families showed association between amount of stainable pollen and number of individuals within the group that set seed. On the basis of the observations, 94.7 percent of the total population had viable pollen in adequate quantities for setting fruit naturally. Association was observed between percentage of stainable pollen and changes in environmental conditions. In studying the inheritance of pollen sterility in a cross between Lookout Mountain and Minnesota Accession 123, stainability was used to differentiate between viable and nonviable pollen. The segregation obtained could be explained by assuming the presence of a tetrasomic gene which, when present in the pollen in the homozygous condition, is lethal and, in the heterozygous condition, partly lethal.

Heritable variations in *Nicotiana tabacum* L. induced by abnormal temperatures, and their evolutionary significance, D. KOSTOFF and M. SARANA (*Jour. Genet.*, 37 (1939), No. 3, pp. 499-547, pls. 2, figs. 6).—Abnormal temperatures induced in *N. tabacum macrophylla* irregularities in mitosis and especially in meiosis, which led to numerical chromosome alterations, aneuploid and euploid, and also induced structural chromosome changes. Progeny of treated plants included structural and numerical variants of various kinds, and additional new variants were obtained by crossing the extreme variants and by further breed-

ing. Chiasma formations between normal and structurally changed chromosomes, between partially homologous unchanged, and probably also between non-homologous ones, conditioned secondary structural changes and variations. Certain variants are considered in connection with the origin of *N. tabacum* and its varieties, and the roles of abnormal temperatures and of other factors inducing hereditary variations in nature are discussed. An extensive bibliography is appended.

An interesting Texas cucurbit—*Cucurbita pepo* L. var. *ovifera* A.lef. (C. texana Gray), A. T. ERWIN. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 12 (1938), No. 2, pp. 253-261, pls. 3).—The author presents evidence that *C. pepo* existed in the southwestern United States ages ago, as shown by archeological remains, and that the Texas form of the same species has survived in the wild over a considerable range in this same region for over a century. It is believed that the preponderance of present evidence favors accepting *C. pepo ovifera* as the prototype of our cultivated forms of this species rather than, as hitherto some have supposed, an escape from cultivation.

Tetraploidy and octoploidy induced by colchicine in diploid *Petunia*, A. LEVAN (*Hereditas*, 25 (1939), No. 2, pp. 109-131, figs. 8).—By soaking seeds in aqueous solutions of colchicine or treating seedlings with colchicine agar, a considerable number of tetraploids, together with single octoploids, are reported to have been originated, the induced changes being somewhat more extreme by the first method. Preliminary data are presented concerning the comparative morphology of diploid, tetraploid, and octoploid petunias, and their interrelationships in general viability are discussed. The cytology of a large number of treated and control plants was studied, the artificial polyploids showing a similar chromosome morphology and a similar course of meiosis to the spontaneous tetraploids. Two types of deviation in meiotic behavior are described. Dissimilarities in reaction to colchicine among various plants are discussed, and as a contrast to the behavior of *Petunia* some experiments with *Beta* are briefly noted and possible causes of the differences obtained are considered. Sixteen references are included.

Tetraploid sugar beets from colchicine treatments, J. RASMUSSEN and A. LEVAN (*Hereditas*, 25 (1939), No. 2, pp. 97-102, figs. 3).—This is a preliminary report on the successful production of tetraploid sugar beets by use of colchicine.

Unfruitfulness in the tomato caused by male sterility, J. W. and M. LESLEY. (Calif. Citrus Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 3, pp. 621-630, figs. 2).—Stating that, because of the normal self-fertility in the tomato, pollen sterility may be a serious crop matter, the authors discuss the results of studies with partially unfruitful plants that occurred in an F_1 population from a simple trisomic F_2 having an extra $H(IV)$ chromosome. The pollen produced by the male-sterile plant was nearly normal in amount, but its development was arrested. A small proportion, perhaps from 2 to 3 percent, of fully developed pollen grains occurred, but apparently did not function successfully. Male sterility was completely recessive and depended on at least two recessive genes, ms_1 and ms_2 , both of which were necessary for male sterility. An apparent 7:1 ratio in one backcross suggested that parents may have differed in a third pair of male-sterility genes, the third dominant allele being introduced by male-fertile parents. The authors suggest that some of the unfruitful plants that occur in commercial tomato varieties may be male-sterile segregates from the selfing of fruitful and apparently normal heterozygous plants.

[Papers on animal genetics, physiology of reproduction, and lactation] (*Amer. Soc. Anim. Prod. Proc.*, 31 (1938), pp. 13-40, 54-57, 67-72, 77-83, 103-

107, 141-146, 223-259, 272-310, figs. 17).—Brief reports were presented on the following subjects before the American Society of Animal Production (E. S. R., 79, p. 318): The Endocrine System—Hormones Elaborated, Their Nature, Interrelations, and General Mode of Action, by L. E. Casida (pp. 13-17) (Wis. Expt. Sta.); Interrelations Between Endocrines, Metabolism, and Productive Efficiencies in Farm Animals, by S. Brody (pp. 17-19) (Mo. Sta.); The Endocrine Control of Growth, by H. H. Cole (pp. 20-26) (Univ. Calif.); Endocrines and Male Reproductive Behavior, by C. R. Moore (pp. 26-29): The Relation of Endocrines to Female Reproduction and Lactation, by C. W. Turner (pp. 29-33) (Mo. Sta.); Combating Sterility With Hormones, by S. A. Asdell (pp. 33, 34) (Cornell Univ.); The Importance of Endocrinology to the Animal Husbandman, by G. H. Hart (pp. 35-40) (Univ. Calif.); Estrus, Ovulation, and Artificial Insemination in Cattle, by G. M. Werner, L. E. Casida, and I. W. Rupel (pp. 54-57) (Univ. Wis.); Nicking in Dairy Cattle, by E. E. Heizer, M. C. Hervey, G. R. Barrett, and G. W. Brandt (pp. 67-72) (Ohio State Univ.); The Accuracy of Measurements and Scores of Draft Horses, by R. W. Phillips, E. B. Krantz, and W. V. Lambert (pp. 77-83) (U. S. D. A.); A Comparison of Several Methods of Measuring Performance in Beef Cattle, by W. H. Black and B. Knapp, Jr. (pp. 103-107) (U. S. D. A.); A Study of Two Methods for Scoring Certain Characters in Swine, by H. O. Ietzer and R. W. Phillips (pp. 141-146) (U. S. D. A.); Conference on Artificial Insemination, by R. W. Phillips and J. C. Miller (pp. 223-228); Variations in Estrus and Ovulation in the Mare and Breeding Results, by F. N. Andrews and F. F. McKenzie (pp. 228-232) (Mo. Sta., Mont. State Col., and U. S. D. A.); Artificial Insemination of Horses and Jennets for Horse, Mule, and Jack-Stock Production—A Preliminary Report, by V. R. Berliner, F. E. Cowart, R. H. Means, and J. B. Wright (pp. 233-237) (Miss. Sta.); Preservation of Fertilising Capacity of Horse Semen, by A. Walton (pp. 238-241); Problems in Long-Range Insemination of Livestock, by R. G. Schott, E. M. Gildow, and R. W. Phillips (pp. 241-246) (U. S. D. A. and Idaho Sta.); Some Factors Affecting Artificial Insemination in Cattle, by H. P. Davis (pp. 246-253) (Nebr. Sta.); Criteria of Fertility in the Bull.—I, The Exhaustion Test, by A. Walton and J. Edwards (pp. 254-259); Relation of Regression to Selection, by W. W. Yapp (pp. 272-277) (Univ. Ill.); The Relationship of Environment to Selection, by L. M. Winters (pp. 278-284) (Univ. Minn.); Some Observations on the Response of Purebred *Bos taurus* and *Bos indicus* Cattle and Their Crossbred Types to Certain Conditions of the Environment, by A. O. Rhoad (pp. 284-295) (U. S. D. A.); Oestrus Cycle of Jennets and Sperm Production of Jacks, by V. R. Berliner, E. W. Sheets, R. H. Means, and F. E. Cowart (pp. 295-308) (Miss. Sta.); A Preliminary Study of the Relation Between the Fleece Characteristics of Weanling and Yearling Range Sheep, by W. V. Lambert, J. I. Hardy, and R. G. Schott (pp. 308-303) (U. S. D. A.); Sex Ratios of Fetal Calves, by A. B. Chapman, L. E. Casida, and A. Cote (pp. 303, 304) (Wis. Sta.); Inbred Sows vs. Inbred Boars in Outcrosses, by O. S. Willham (pp. 304-307) (Okla. Sta.); and Reproductive Capacity of Rambouillet Ram Lambs as Indicated by Semen Tests, by C. E. Terrill (pp. 308-310) (U. S. D. A.).

Blood value of cross-breeds between the wild *Ovis polii karelini* Sew. and the domestic sheep, V. I. PATEUSHIEV (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 21 (1938), No. 1-2, pp. 63-67*).—Study of the blood factors of 345 sheep, including hybrids and backcrosses between the wild *O. polii karelini* and the New-Caucasian Merino, Prococo, and Kurdyuk, showed that in glutathione concentration, dry residue and specific gravity of the blood, and resistance of erythrocytes to solution the hybrids excelled the purebreds. These conditions seemed to be controlled by multiple factors. Crossbred lambs

between the wild *O. polii karelini* and the Merino were larger at birth than the Merinos or other crossbreds. Triple hybrids (*O. polii karelini* × Merino × Precocce) showed more rapid growth and were larger than the first crosses at 18 mo.

Investigations on twinning in German Improved sheep (Württemberg) with special reference to the Hohenheim strains [trans. title], K. BIEGER (Ztschr. Tierzücht. u. Züchtungsbiol., 42 (1938), No. 2, pp. 215-258, figs. 21).—Data are reported on the percentages of twins born in 13 Württemberger flocks from 1922 to 1936. Variations in the climatic conditions were noted but were not definitely associated with twinning. The tendency to twinning increased with the age of the ewes, and variations in twinning were associated with the sires and dams. The tendency seemed to be hereditary.

[Investigations in poultry genetics by the Massachusetts Station], F. A. HAYS and R. SANBORN (Massachusetts Sta. Bul. 355 (1939), pp. 91, 92, 93).—Results are briefly presented which show differences in the amount of broodiness, rate of production, mortality, and early feathering in selected strains of Rhode Island Reds.

Studies on sauropsid chromosomes.—V, The karyotypes of the quail and the duck, different from those reported by previous authors, K. OGUMA (Annot. Zool. Jap., 17 (1938), No. 3-4, pp. 612-623, figs. 17).—Continuing these papers, in part previously noted (E. S. R., 58, p. 218), reports are given on cytological studies of adult testes from the quail and duck and embryonic testes and ovaries from the duck. It was observed that the diploid chromosome numbers in ♂ were 78 and 80, respectively. The ♀ duck had 79.

The origin of the total albino variety of the shell parakeet, H. BUTZ and W. SCHNELLE (Ztschr. Tierzücht. u. Züchtungsbiol., 42 (1938), No. 2, pp. 259-268).—An explanation of albinism due to a sex-linked recessive gene.

Internal secretions in reproduction, E. ALLEN (In Science in Progress, edited by G. A. BAITSSELL. New Haven, Conn.: Yale Univ. Press; London: Oxford Univ. Press, 1939, pp. 180-209, figs. 18).—A summary of the endocrines related to reproduction and lactation is given.

The ovarian condition and sexual behavior in the female guinea pig, W. C. YOUNG, E. W. DEMPSEY, H. I. MYERS, and C. W. HAGQUIST (Amer. Jour. Anat., 63 (1938), No. 3, pp. 457-487, pls. 2).—Studies of the relation of the condition of the ovaries to sexual behavior in 17 immature and 207 sexually mature guinea pigs showed much variation, but important factors in the ovarian condition seemed to be the time required to complete ovulation; temporary or permanent variation in individual sensitivity to oestrin-progesterone, or other hormones; and action or reaction and number of ruptured follicles. In general in the guinea pig the ovary reflects the stimuli from the hypophysis, and its action is limited by the responsiveness of the somatic tissues on which its secretions act. Following removal of one ovary, the number of maturing follicles remaining in the other ovary was doubled.

Cellular changes in the anterior hypophysis during the reproductive cycle in the female guinea pig, C. W. HAGQUIST (Anat. Rec., 72 (1938), No. 2, pp. 211-229, figs. 5).—Variations in the percentages of the different cell types found in the hypophysis of ♀ guinea pigs at eight stages of the reproductive cycle commencing with the copulatory stage were not considered statistically significant. However, the Golgi apparatus hypertrophies during the first half and becomes fragmented during the second half of the cycle. Changes in the concentration of the mitochondria were associated with heat production. Pituitary conditions were not associated with the number and stage of follicular development.

A quantitative study of the influence of the ovarian hormones on hyperplasia by mitosis in the rabbit uterus in early pregnancy, W. D. CRANDALL (*Anat. Rec.*, 72 (1938), No. 2, pp. 195-210, figs. 2).—Hyperplasia of the circular muscle cells and associated connective tissue cells was found to occur by mitosis in the uterus of the rabbit during the first week of pregnancy. Studies of the effects of subsequent ovariectomy and the administration of oestrin or progesterone suggested that the hyperplasia is induced by the action of these hormones and that mitosis in the muscle cells was induced by progesterone and to a lesser extent by oestrin, whereas mitosis of the connective tissue cells resulted mainly from oestrin alone.

The manifold effects of prolonged administration of sex hormones to female rats, V. KORENCHESKY, K. HALL, and R. BURBANK (*Biochem. Jour.*, 33 (1939), No. 3, pp. 372-380).—Studies of the effects on the organs of spayed rats of injections for about 3.5 mo. of androsterone, transdehydroandrosterone, testosterone propionate, and oestradiol dipropionate, alone, or each of the δ hormones in combination with the ϕ hormone and with progesterone showed that the vagina could be completely restored but the uterus not entirely to normal weight by the administration of oestradiol dipropionate. Testosterone propionate alone produced pronounced progestational changes in the uterus and less strong ones in the vagina, whereas the other androgens had little effect on the uterus but the vagina and preputial glands were hypertrophied. Cooperative action between the δ and ϕ hormones in their action on the uterus was noted, but the addition of progesterone to the combination of testosterone and oestradiol inhibited the uterine weight increase. The influence of the hormones on other organs was observed. The effects of testosterone propionate on normal rats were similar to those observed in the ovariectomized ϕ ϕ .

Sperm formation and growth of accessory reproductive organs in hypophysectomized ground squirrels in response to substances from blood and human urine, L. J. WELLS and M. D. OVERHOLSER. (Univ. Mo.). (*Anat. Rec.*, 72 (1938), No. 2, pp. 231-247, pls. 2, fig. 1).—Treatment of hypophysectomized immature and mature δ ground squirrels with extracts of human δ urine, pregnant-mare serum, and pregnancy urine induced the formation of spermatozoa in the epididymis in the nonbreeding season. Accessory reproductive organs were stimulated, as judged by their size and histological characteristics.

Preliminary extraction of gonadotrophic principle from pregnant mare serum, H. RINDERKNECHT, R. L. NOBLE, and P. C. WILLIAMS (*Biochem. Jour.*, 33 (1939), No. 3, pp. 381-384, figs. 2).—A method for purification of the gonadotrophic hormone in pregnant-mare serum by precipitation with salicylsulfonic acid and subsequent fractionation and purification is described. The resulting water-soluble white powder represents about a thousandfold purification of the solids in the original serum.

The action of the dipropionate and benzoate-butyrate of oestradiol on ovariectomized rats, V. KORENCHESKY, R. BURBANK, and K. HALL (*Biochem. Jour.*, 33 (1939), No. 3, pp. 366-371).—Comparison of the effects of these substances in three weekly injections of 18 and 90 μ g. into spayed rats showed that the vagina and clitoris were more than restored to normal weight for a period as long as 106 days after treatment with the benzoate-butyrate ceased. The weight of the uterus was increased but was not restored to normal weight except in the group treated for 19 weeks with 300 μ g. of benzoate per week. During the long-continued effects after injections ceased, the structure of the vagina was changed from the oestrous to the progestational form, probably from the cooperative action of the small amount of oestrogenic hormone with progesterone from the adrenals. The effects of the treatment on other organs and tissues were also noted.

Stability of testis hormone, D. R. McCULLAGH (*Endocrinology*, 24 (1939), No. 3, pp. 326-330).—Studies were made of the capon comb development induced by testosterone and testis extracts before and after boiling. Testosterone was inactivated very slowly by boiling with 5 percent sulfuric acid for as long as 5 hr. Boiling the extracts for 15 min. with acid had variable effects. These results are taken to indicate the presence of more than one androgen in the testicular extracts.

Progesterone is androgenic, R. R. GREENE, M. W. BURELL, and A. C. IVY (*Endocrinology*, 24 (1939), No. 3, pp. 351-357, figs. 2).—Progesterone and prostestin were both found to stimulate growth of the prostates and to a lesser extent the seminal vesicles of immature normal and immature and adult castrated ♂ rats. Progesterone also stimulated growth in the size of the clitoris of mature ♀♀. Thus this substance seemed to have androgenic properties.

The effect of temperature on the response of Bantam capons to androsterone, A. M. HAIN (*Quart. Jour. Expt. Physiol. and Cog. Med. Sci.*, 28 (1938), No. 4, pp. 353-355).—Comb growth as determined by increase in the length and height in capon Bantams was found to be related to the dose of androsterone administered on 5 successive days. With 0.25 mg. of androsterone the average growth at a temperature of from 40° to 48° F. was 3.4 mm. as compared with 10 mm. with doses of 1.5 mg. at the same temperature. Temperature also had an important influence, as doses of 0.5 mg. of androsterone caused comb growth of 5.75, 3.3, and about 2.5 mm. when the temperatures of the house ranged from 40° to 48°, 50° to 64°, and 53° to 74°, respectively.

Comb atrophy after adult castration (Bantam cocks), A. M. HAIN (*Quart. Jour. Expt. Physiol. and Cog. Med. Sci.*, 28 (1938), No. 4, pp. 349-352, figs. 3).—Data are reported on the regression in height and length of the combs of 100 Bantams following adult castration. Regression in the length was close to 40 percent, but the regression in height varied with the initial size. The heights to which the combs of adults regressed were much greater than the heights of the combs of immature castrates.

Influence of parity on litter size as well as relation of litter size and parity to mortality in white mice during the suckling period [trans. title], S. WANKE (*Ztschr. Tierzucht. u. Züchtungsbiol.*, 42 (1938), No. 2, pp. 269-280).—Study of 7,916 litters of white mice showed that second litters were largest and experienced the lowest mortality during suckling.

Blood value of Yaroslavl cattle in correlation with body weight and yield of milk, V. I. PATRUSHEV (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S.*, n ser., 21 (1938), No. 1-2, pp. 89-93, figs. 3).—Age and sex differences in the blood analyses of Yaroslavl cattle were noted, but on the average greater body weight was associated with higher resistance of the red cells to solution, higher concentrations of glutathione, and higher specific gravity and dry residue in the blood characteristics. The catalase activity and resistance of erythrocytes were associated with milk yield.

The influence of domestication of silver foxes on their anatomical characteristics [trans. title], G. MÜLLER (*Ztschr. Tierzucht. u. Züchtungsbiol.*, 42 (1938), No. 2, pp. 281-302, figs. 10).—The weights and measurements of various organs and parts of 58 silver and red foxes are presented and discussed.

Prenatal and postnatal sex ratio in sheep, W. L. HENNING. (Pa. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 8, pp. 565-580, fig. 1).—From 1923 to 1937 there were 875 ♂ and 867 ♀ lambs born in the station flocks of all breeds, a sex ratio of 50.2 ± 1.20 percent ♂. Sex ratios of Southdown lambs registered confirmed the assumption that only a portion of the rams are recorded, but there seemed to be a greater tendency to select rams born as twins

than as singles. Sex ratios of 972 fetuses of various ages from packing house and other material showed 50.9 ± 1.60 percent ♂♂. Timed fetuses and fetuses of different lengths and weights did not show significant differences in the sex ratios. There was greater mortality of both sexes in the larger litters. Growth curves for weight and length were calculated from data on 38 fetuses of known intra-uterine age.

Contribution to the knowledge of sexual reproduction in Karakul sheep in reference to artificial insemination [trans. title], U. HÖCKER (*Kühn Arch.*, 47 (1938), pp. 27-77, figs. 2).—Concerning the fertility of ewes and rams, studies were made of the motility of semen from different ♂♂ by the use of recommended methods of artificial insemination with collection of semen in an artificial vagina and preservation of it at from 6° to 10° C. A total of 54.2 percent of the artificially inseminated ewes lambed as compared with 31.8 percent following normal matings.

The possibility of early sex determination in fowls [trans. title], J. FORSTHOFF (*Ztschr. Tierzücht. u. Züchtungsbiol.*, 41 (1938), No. 1, pp. 28-39).—A review is given of early sex determination in fowls and the methods whereby sex may be identified at hatching by the use of sex-linked genes in suitable crosses.

FIELD CROPS

Productive farm crops, E. G. MONTGOMERY (*Chicago: J. B. Lippincott Co.*, 1938, 5. ed., rev., pp. IX+521, [pl. 1], figs. 203).—A fifth and revised edition of a book noted earlier (E. S. R., 60, p. 635).

[Agronomic experiments in Connecticut] (*Connecticut [New Haven] Sta. Bul.* 421 (1939), pp. 38, 39, 42, 43-45, 46).—Progress results are again (E. S. R., 79, p. 321) noted briefly from breeding work with corn and corn hybrids, fertilizer tests with potatoes and sweetpotatoes, and tobacco investigations at Windsor (see p. 509), including studies on the role of yeasts in tobacco fermentation.

[Field crops work in Kentucky] (*Kentucky Sta. Rpt.* 1938, pt. 1, pp. 19, 21, 25, 26, 35-37, 38, 39-44, 50, 52, 53, 55).—Research with field crops (E. S. R., 79, p. 471) reported on again from the station and substation included variety tests with corn, wheat, potatoes, alfalfa, and red clover; breeding work with corn (and hybrids), wheat, tobacco for low nicotine, and bluegrass; rotation, fertilizer, topping and suckering, and curing experiments with tobacco; nitrate level in soil under Burley tobacco and effects on growth; fertilizer and variety tests with sorgho for sirup; response of wheat, clover, tobacco, and corn to liming; fertilized and limed crop rotations; studies of the relation of variety, starch storage and utilization, and soil productivity to red clover failure; determinations of the phosphorus contents of corn, wheat, buckwheat, pasture herbage, and other variously treated crops; and pasture experiments.

[Field crops experiments in Massachusetts], W. S. EISENMENGER, K. J. KUCINSKI, W. G. COLBY, R. W. DONALDSON, L. S. DICKINSON, H. M. YEGIAN, and C. E. CROSS. (Partly coop. U. S. D. A.). (*Massachusetts Sta. Bul.* 355 (1939), pp. 10-12, 17-19, 20, 41-43).—Investigations for which results are again (E. S. R., 79, p. 471) reported briefly included variety trials with potatoes and alfalfa; effects on yield and quality of tobacco due to several spacings, to different treatments to old hay sod preceding tobacco, and to the influence of different weeds, crops, and vegetables, especially as to lignin content, when preceding tobacco (E. S. R., 79, p. 327); comparisons of hay seeding mixtures and effects of potash top dressing on meadows; influence of time of cutting on yields and of the use of potash in preventing winter-killing of alfalfa; pasture experiments, including tillage, fertilizer, and reseeding; use of calcium cyanamide to control

crabgrass in Kentucky bluegrass lawns; and chemical control of cranberry bog weeds.

[Field crop experiments at the Puerto Rico College Station], A. ROQUE, J. ADRIAR, J. PASTOR RODRÍGUEZ, F. MÍNDIZ, L. A. SERRANO, C. J. CLAVELL, F. CHARDÓN, P. RICHARDSON KUNTZ, E. MOLINERY SALLS, F. J. JULIÁ, and A. RIOLLANO (*Puerto Rico Col. Sta. Rpt. 1938*, pp. 46-48, 64, 66-71, 73-75, 76, 77, 78-80, 81, 83, 85, fig. 1).—Experimentation with field crops (El. S. R., 79, p. 618) reported on from the station and the Isabela Substation included variety, uniformity, irrigation, fertilizer, soil reaction, trash disposal, and green manuring (*Crotalaria striata*) tests, all with sugarcane; forage production of variously fertilized grasses on hillsides and lowlands; fertilizer tests with corn, beans, alfalfa, and potatoes; breeding work with corn, cotton, beans, tobacco, and sugarcane; and variety trials with tobacco, sweetpotatoes, soybeans, beans, legumes for cover crops and green manure, cassava, yams, and yautias.

[Field crops investigations in Wisconsin, 1937-38]. (Partly coop. U. S. D. A. et al.). (*Wisconsin Sta. Bul. 443 (1939)*, pp. 3-5, 6, 7, 8, 43, 44, 58-77, figs. 7).—Progress reports are made again (El. S. R., 79, p. 618) from agronomic research at the station and substations, comprising curing by artificial heat and fertilizer and rotation experiments, both with tobacco, by W. B. Ogden and J. Johnson; comparative trials of Chippewa, Sebago, and other potato varieties, by G. H. Rieman; time of culing tests with alfalfa, by E. M. Searls, with feeding tests with dairy heifers on the several cuttings in cooperation with G. Bohstedt, I. W. Rupel, and B. H. Roche; effects of plowed under combine grain straw on the following crops, and seeding, cultural, fertilizer, and management practices for alfalfa in the Hancock area, both by A. R. Albert; use of the cultipacker seeder in improving stands of meadows, by H. L. Ahlgren, O. S. Aamodt, and F. W. Duffee; breeding of improved varieties of Sudan grass, particularly for reduced HCN content, by Ahlgren, P. Hogg, and Aamodt; comparative resistance of domestic ryegrass and timothy to Wisconsin winters, by Ahlgren and Aamodt; yields of foreign v. American and Canadian red clover, by Aamodt and J. H. Torrie; merits of sweetclover-alsike-timothy as a hay mixture in central Wisconsin, by E. J. Delwiche; research on seed formation in alfalfa (El. S. R., 80, p. 613), by R. A. Brink and D. C. Cooper; the value of white clover in pasture and its response to culture, fertilizers, and grazing, by Ahlgren, F. W. Tinney, and Aamodt; response of bluegrass pasture to rotational grazing and nitrogen fertilization, by Aamodt, Ahlgren, Rupel, Bohstedt, E. J. Gaul, and Tinney; varieties of oats, barley, spring and winter wheat, and rye outstanding in tests in northern and central Wisconsin and date of seeding tests with winter wheat and other small grains, by Delwiche, A. L. Bibby, D. H. Holt, E. Hirsch, and W. Carlson; breeding work with barley, by H. L. and R. G. Shands, with oats by Shands and Torrie, and with winter and spring wheat, all for yield and resistance to disease and other qualities, and with potatoes, by T. C. Allen and Reiman, for resistance to hopperburn; corn hybrid investigations, by N. P. Neal, A. H. Wright, Delwiche, and A. M. Strommen, concerned with the relative merits of Wisconsin and introduced hybrids and progress of the use of hybrid corn in the State, and the development of hybrid corn for northern Wisconsin; methods of handling seed corn, including improvement in a slatted floor seed corn drier, development of a seed corn grader, and studies of effects of storage conditions, especially moisture content and chemical dusts, on germination, by Wright and Duffee.

[Experiments with field crops in Wyoming]. (Partly coop. U. S. D. A.). (*Wyoming Sta. Rpt. 1938*, pp. 3-5, 6, 20, 30, 31, 31-33, 34-38, 39, 40).—Agronomic experiments (El. S. R., 79, p. 43) at the station and substations, reported on

briefly, included variety tests with winter and spring wheat, oats, barley, flax, corn, potatoes, alfalfa for yield and wilt resistance, field peas and miscellaneous forage grasses and mixtures; dry land v. irrigated potato seed and spray treatments and tuber index tests with potatoes; cultural (including planting) experiments with winter and spring wheat, barley, oats, corn, potatoes, sugar beets, crested wheatgrass, brome grass, and alfalfa; fertilizer trials with potatoes (phosphate), alfalfa, and sugar beets; ordinary, manured and fertilized, and pastured crop rotations; methods of preparing seedbeds for different crops; trials of alfalfa in mixtures with grasses; response of alfalfa to cultivation and manure; pasture studies; and control of quackgrass.

Diurnal cycle of heat resistance in plants, H. H. LAUDE. (Kans. Expt. Sta.). (*Science*, 89 (1939), No. 2320, pp. 556, 557).—A daily cycle of heat resistance in plants was observed in corn, wheat, barley, sorghum, and alfalfa. The daily maximum resistance to heat was attained by plants at about mid-day and continued during afternoon. The minimum resistance prevailed early in the morning. Resistance to heat increased when plants were exposed to light and decreased in absence of light. One hour of light following normal darkness of night was long enough for plants to acquire a measurable and, in some cases, marked resistance to heat. Ordinarily plants reached their daily maximum heat resistance within 4 hr. after exposure to daylight following normal night. Plants exposed to electric light during the night were more resistant to heat in early morning than those kept in the dark during the night. Loss of heat resistance in plants when exposed to darkness was slower than gain of resistance in the presence of light.

Some effects of temperature on the growth and chemical composition of certain pasture grasses, E. M. BROWN. (Coop. U. S. D. A.). (*Missouri Sta. Res. Bul.* 299 (1939), pp. 76, figs. 33).—Established cultures of Kentucky and Canada bluegrasses, orchard grass, and Bermuda grass were grown in thermoregulated growth chambers, and effects of temperature treatments (40°, 50°, 60°, 70°, 80°, 90°, and 100° F.) on growth and chemical composition were determined for periods approximating 8 weeks.

The bluegrasses and orchard grass made considerable growth at 40°, while Bermuda grass made no growth at 40° and very little at 50°. Optimum temperatures for herbage production were between 80° and 90° for the bluegrasses and 70° for orchard grass. Bermuda grass made more herbage at 100° than lower temperatures. For root and rhizome production the optimum was 60° for Kentucky bluegrass and 50° for Canada bluegrass. Orchard grass made maximum root growth at 70°, while root growth by Bermuda grass increased with each 10° rise to 100°. The bluegrasses and orchard grass especially were severely injured by a continuous air and soil temperature of 100°, largely due to the high soil temperature. Rhizomes of Kentucky bluegrass tended to remain below the soil line at 80° or lower and those of Canada bluegrass at 50° or lower. Higher temperatures stimulated emergence of growing points of rhizomes above the soil line.

In the bluegrasses and orchard grass the percentage content of nitrogen-free extract declined but increased in Bermuda grass with rising temperature. In all four grasses the crude fiber content rose with the temperature from 40° to 60° and changed little with further rises in temperature. The crude protein percentage declined slightly in the bluegrasses and orchard grass as temperature rose from 40° to 60° and then increased slightly as the temperature went above optimum for growth. Crude protein content in Bermuda grass was much greater at 50° than at 60°. When plants were exposed to variable temperature effects of high day temperature appeared to be counter-

balanced by low night temperature as to the chemical composition of the plant. This was also true for the growth of orchard grass, but the other three grasses responded to diurnal temperature variations as high day temperature exerted more influence than low night temperature on growth.

A review of literature on effects of temperature on the growth and chemical composition of plants includes 28 titles.

The utilization of water by alfalfa (*Medicago sativa*) and by bluegrass (*Poa pratensis*) in relation to managerial treatments, V. G. SPRAGUE and L. F. GRABER. (Wis. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 30 (1938), No. 12, pp. 986-997, figs. 2).—Water use by alfalfa and Kentucky bluegrass was compared in the greenhouse with optimum moisture conditions and under frequent and deferred cutting treatments, with and without nitrogen fertilization. The daily rate of water use was low in vegetative growth stages but increased directly with the rate of top growth accumulation, was very high with plants approaching maturity, and was low and quite constant with weekly clippings which maintained a vegetative state of growth. Weekly defoliations of well-established, high-reserve alfalfa greatly reduced the total water used and water requirement during the first 65 days of growth. Such defoliations also reduced the total water used by bluegrass, but water needs were not affected greatly.

After-effects of nine weekly defoliations, which lowered the food reserves of alfalfa moderately and those of closely clipped bluegrass very severely, were evident in markedly reduced subsequent top growth and total amount of water used to produce it, and increases in amount needed to produce one unit of dry top growth. The tendency was noted for nitrogen fertilizations to increase total water used but to decrease water needed per unit of dry matter produced. In periods pending drought, early cutting of alfalfa and close early grazing of bluegrass would tend to maintain a greater moisture reserve in the soil for subsequent growth than would prevail with deferred grazing or cutting. See also an earlier note (E. S. R., 79, p. 187).

The effect of different fertilizer ratios on Colonial, creeping, and velvet bent grasses, J. A. DEFRAE. (R. I. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 773-780, figs. 2).—Study of the effects of different fertilizer ratios on three bentgrasses, 1933-37, showed that the most vigorous growth was obtained from fertilizers high in nitrogen and phosphorus, with no increase in vigor from addition of potassium. Varying amounts of nitrogen influenced color ratings the most, addition of phosphorus and potassium having little beneficial effect. Low nitrogen, in general, developed the finest textured turf, the reverse from the highest ratings of color, density, and vigor from use of high nitrogen. The densest turf resulted from high nitrogen and the thinnest from the low nitrogen. High phosphorus plats of Piper and Rhode Island bent surpassed all but the high nitrogen plats. Nitrogen appeared to be mainly responsible for density, with phosphorus assisting to some extent.

Although the high nitrogen fertilizer gave the highest quality ratings for vigor, color, and density, the turf grew too rapidly and was too spongy for practical putting green conditions. While the low nitrogen plats had the highest rating of texture, they were more susceptible to invasion of clover and weeds, had a hard surface, and were more subject to drying out than were other plats. A complete mixture, as 10-6-4 or 10-12-4, with nitrogen from both organic and inorganic sources seemed best for general application as a top dressing fertilizer.

The high phosphorus and low nitrogen favored growth of clover, while high nitrogen discouraged the invasion of clover, crabgrass, and plantain. Broad-leaved plantain was the most troublesome weed other than crabgrass in the first 2 yr. Very few weeds of any kind appeared during the last 3 yr. Large brown

patch disease was least severe on the high potassium and low nitrogen plats. On Rhode Island and Washington bent, dollar spot was most severe on the low nitrogen and least severe on the high nitrogen plats. Piper velvet was 100 percent resistant to dollar spot.

Piper velvet bent was outstanding and appeared more satisfactory than Rhode Island Colonial bent or Washington creeping bent in quality ratings based on density, texture, and color and weed and disease resistance.

Growing grass under trees, H. B. SPRAGUE. (N. J. Expt. Stas.). (*Shade Tree*, 12 (1939), No. 4, pp. [2, 3]).—Practical suggestions on species and cultural and fertilizer practices.

Studies on the nitrogen, phosphorus, and mineral requirements of alfalfa, A. W. BLAIR and A. L. PRINCE. (N. J. Expt. Stas.). (*Soil Sci.*, 47 (1939), No. 6, pp. 459-466).—Alfalfa was grown 1935-38, inclusive, on $\frac{1}{4}$ -acre plats of Sassafras loam that had received no phosphorus since 1924 and on plats receiving varying amounts of phosphorus annually. Potassium was applied uniformly to all plats, but nitrogen was limited to a small amount at seeding.

Yields from check plats averaged about the same as those receiving the highest amount of phosphorus. The hay tended slightly toward a higher percentage of phosphorus with increase in phosphorus applied, which did not influence the percentages of nitrogen, ash, CaO, and MgO in the hay. The percentage of CaO was from five to seven times as high as the percentage of MgO. Soil taken from the plats in 1932, 1935, and 1937 showed a tendency toward a slight increase in the total phosphorus content with increase in the amount applied. Profile samples from soil receiving the maximum phosphorus application showed slightly more phosphorus in the 6-in. layers down to 30 in. than soil receiving no phosphorus. Indications of a reservoir of phosphorus in the 42-in. layer amounting to from 10,000 to 12,500 lb. P_2O_5 per acre suggested an explanation for the failure of alfalfa to respond to phosphorus treatment. The results reported are for the experimental conditions and are not to be taken as endorsing the omission of phosphorus from alfalfa fertilizers.

Starch reserves in the roots of pastured alfalfa when grown alone and in mixtures, H. C. RATHER and C. M. HARRISON (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 4, pp. 281-291, figs. 4).—Certain of the problems involved in grazing alfalfa and alfalfa-grass mixtures were studied at Augusta by biweekly examination of alfalfa roots for starch reserves and by measuring ewe and lamb gains during the pasture season.

Alfalfa roots were lowest in starch reserves during the period of most active growth in the spring. The reserves became depleted with close grazing or following a close cutting. Alfalfa or alfalfa and smooth brome grass in mixture returned far greater net gains per acre with sheep than did any native pasture plants when compared on a season-long grazing basis. Alfalfa and orchard grass mixture was poor because of difference in palatability of the plants and resulted in over-grazing and consequent death of the alfalfa. The difference in palatability of orchard and smooth brome grasses could be judged by the condition of the alfalfa roots when orchard grass was unpalatable in relation to brome grass. Starch reserves in alfalfa roots previous to killing frosts were necessary to prevent carbohydrate starvation and subsequent winter-killing. Alfalfa, grown alone, stored starch in the roots much more readily than in mixture with grass.

Sheep gains were the largest in the first part of the grazing season when forage was succulent and produced much faster than a reasonable number of animals could graze it.

Curing and storage of alfalfa hay, E. R. HENSON (*Iowa Sta. Res. Bul.* 251 (1939), pp. 46, figs. 7).—Results of experiments on methods of curing and

storing alfalfa hay are reported, with a review of literature on various aspects of these subjects embracing 78 titles.

Alfalfa hay cured more rapidly in the swath than in the windrow and faster in the windrow than when cocked. Hay one-fourth, one-half, or three-fourths cured in the swath prior to windrowing cured faster than hay windrowed at once, and the longer the hay remained in the swath the less time it required for curing. Cocking hay at once or after partial swath or windrow-curing delayed curing. Green hay in large cocks heated and lost its color, yet good quality hay was made by cocking after partial swath or windrow-curing. Turning average sized windrows with the rake in good curing weather was slightly detrimental, although turning large windrows or windrows wet by rain resulted in faster curing and a better quality of hay. Tedding hay had no advantages in these tests and was detrimental to the quality of the hay. Complete swath-curing resulted in the greatest loss of leaves, three-fourth and one-half swath-curing were next, while windrowing at once and one-fourth swath-curing followed by windrowing resulted in the least loss. Leaf loss in swath-curing hay was increased by the tedder, and turning of the windrow with the rake caused additional loss in windrow-cured hay.

The evidence and theories on heating of hay indicated that heating is due largely to chemical oxidation processes. These processes may be aided by respiration of the living cells in the plant up to 40°-45° C. and by the work of microorganisms from air temperatures to 70° in producing unstable, unsaturated compounds. Beyond this point the heating seemed due entirely to chemical processes. The presence of living cells in the stems and leaves of field-cured hay plants was shown.

Although hay placed in the mow ranged from 20 to 58.7 percent of moisture, the degree of heating was not directly proportional to moisture content. Hay with below 30 percent of moisture ordinarily may be considered safe from destructive or dangerous heating, and hay with less than 27 percent of moisture may be expected to retain its green color. The hay generally heats immediately on being mowed, then cools. In a second heating period which follows, the highest temperature usually is reached in from 8 to 10 days after mowing, after which the hay cools gradually. The amount of carbon dioxide present in the mow is deemed a fair indication of the degree of heating. Its accumulation in the presence of moist, hot material results in a transformation of the chlorophyll, accompanied by a change in color from green to brown. The green color of hay usually was destroyed when heating exceeded 50°. Clean, brown hay was formed by heating quickly to 55°, while prolonged heating at 50° or lower and later heating to above 55° resulted in dusty hay. In general, moldy, grayish-brown hay resulted from heating to between 40° and 50° during storage. Marked benefits from salting hay occurred in only one of six trials. No detrimental heating occurred when hay baled from the field with 23 percent of moisture was carefully stored.

Seed corn, M. T. JENKINS (*U. S. Dept. Agr., Farmers' Bul. 1822 (1939), pp. 11-14, figs. 7*).—Intended primarily for the grower who maintains and endeavors to improve his locally adapted strain of open-pollinated corn by careful mass selection, this bulletin discusses choice of strains, improvement by mass and field selection, desirable plant characteristics, drying and winter storage of seed corn, germination tests, shelling and grading, prevention of injury by weevil or grain moths, and seed treatments. The publication supersedes *Farmers' Bulletin 1175 (E. S. R., 44, p. 230)*. The breeding and development of corn hybrids is discussed elsewhere (*E. S. R., 73, p. 36*).

Sand culture of cotton plants, H. S. OLCOCK (*Science, 89 (1939), No. 2322, pp. 608, 609*).—Technic and a nutrient solution are described.

The effect of length of dormant period of seed Irish potatoes on yield, W. D. KIMBROUGH. (La. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 590-592).—Respective average yields of No. 1 tubers grown, 1936-38, from northern grown (5 months' dormancy), Louisiana spring grown (9 mo.), and Louisiana fall grown (3 mo.) were for Katahdin 253.7, 220.5, and 173.3 bu.; Chippewa 218.3, 98.3, and 172; Honna 216.5, 110.1, and 115.9; and Triumph 190.5, 116.6, and 132.9 bu. Differences in sprouting and plant production are described. "For best results the dormant period should be long enough for the seed pieces to sprout rapidly when planted and the resultant plants to grow vigorously, but not long enough to produce multiple sprouting and stunted early maturing plants."

Effects of certain chemicals on apical dominance and rest period of Russet Burbank potatoes, G. W. WOODBURY. (Idaho Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 601-604, fig. 1).—Russet Burbank potatoes, treated with 4 percent aqueous solutions of potassium thiocyanate and thiourea, gave marked increases in sprout production. Evidence of shortening of the rest period, shown in earlier plantings, gradually disappeared until the normal termination of the rest period. Similar treatments to seed potatoes planted in the field resulted in increased number of stems and tubers per hill with a reduction in tuber size.

Fertilizer placement for potatoes, G. A. CUMINGS and G. V. C. HOUGHLAND. (Coop. Me., Mich., Ohio, N. J., [N. Y.] Cornell, and Va. Truck Expt. Stas. et al.). (*U. S. Dept. Agr., Tech. Bul.* 669 (1939), pp. [2]+48, figs. 22).—Experiments on the placement of fertilizer for potatoes (E. S. R., 76, p. 620; 81, p. 305) were made, 1931-37, in Aroostook County, Me., on Long Island, N. Y., in central New Jersey, on the eastern shore of Virginia, in northeastern Ohio, and in western Michigan. Fertilizers of both single- and double-strength grades were applied at the usual rates per acre and at other rates on typical potato soils of each district.

Fertilizer placed in a band at each side of the row usually produced the most rapid emergence of sprouts, most vigorous plant growth, and highest yields of primes and total yields. The preferable placement from a practical viewpoint was in a band 2 in. to each side of and on the lower level of the seed piece. Placement in a band at only one side of the row gave lower yields than a band at each side, and placement in a band immediately under, or above, or mixed with the soil around the seed piece usually resulted in delayed sprout emergence and reduction in yield. Single- and double-strength fertilizers supplying equivalent amounts of plant food gave similar results in actual potato yields and order of yields for various placements. Hill placement of fertilizer in short bands at each seed piece or hill had no advantage over comparable placements in continuous bands for seed spacings ranging from 12 to 16 in.

Storage treatment of soybeans with ethylene and carbon dioxide gas, C. H. WORSHAM, C. C. WADDELL, and F. C. VILBRANDT (*Va. Engin. Expt. Sta. Bul.* 36 (1939), pp. 34, figs. 15).—Field run soybeans were treated in gas-tight silos through which mixtures of gases varying from 90 to 35 percent ethylene and from 10 to 65 percent carbon dioxide and air were recirculated to mature and stabilize the beans and to prevent peroxidase action, the latter being blamed with imparting the offensive odor and taste to the oil and meal. Whole beans treated for 24 and 48 hr. at 24°, 37°, and 50° C. were then rolled flat in a roll mill and expressed at 45°-60° in a hydraulic press at 10,000 lb. per square inch.

Oil from soybeans treated with ethylene and carbon dioxide mixture kept better than oil from those treated with air, remaining in good condition at

least 8 mo after processing. Soybeans treated with a high concentration of ethylene gave oil with the best taste and odor, which declined very slightly with lower concentration of ethylene. Whole beans treated with ethylene at 24° gave the best oil, slightly superior to that from beans treated at 37°. Soybeans absorbed varying amounts of ethylene and carbon dioxide, depending on the gas concentration and the water removed. The rate of drying by air was considerably less than the drying rate when ethylene and carbon dioxide were used.

Studies of gaps in sugarcane rows and their effect upon yield under Louisiana conditions. G. ARCENEFAUX and I. E. STOKES (*U. S. Dept. Agr. Cir. 521 (1939), pp. 20, figs. 5*)—Under conditions prevailing in southern Louisiana, the extent of gaps in sugarcane has been found to vary widely under different conditions and with different varieties. With the previously grown P. O. J. varieties, gaps in plant cane to as much as 30 to 40 percent of the row space were generally found. As a group the C. P. and Co. varieties currently grown showed much lower percentages of gaps than ordinarily were found in the P. O. J. canes, but under certain conditions even they have given very imperfect stands. In controlled experiments the loss in sugar yield resulting from a gap of a given length was shown to be considerably less than the normal production of sugar from the area the gap occupied, indicating that extensive compensatory growth is made by stools adjoining gaps. The actual value of the yield-reduction factor, i. e., the extent to which observed loss in sugar yield from a given gap approaches the normal production of the area involved, was found to depend on length of the gap, variety involved, and crop year. Short gaps reduced yields much less than equivalent space in longer gaps. Co. 281 showed the greatest relative yield loss from a given gappage and Co. 290 the least. The highest yield loss from gaps of plant-cane origin occurred in the plant-cane crop. A formula is suggested for estimating losses in yield of sugar per acre from gaps under specific conditions.

Further studies and technic in sweet potato breeding in Louisiana. J. C. MILLER (*La. Expt. Sta.*). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 665-667).—The technic described is based on experiments in the field and greenhouse during 1937 and 1938 on comparative methods of producing seed and seedling sweetpotatoes. The plants are carried over the winter in the greenhouse in from 10- to 12-in. pots and are moved to the field when danger of frost is past. Vines are trained fan-shape to a wire trellis about 7 ft. high. Plants are spaced about from 8 to 10 ft. apart in the row, and as soon as the vines become established in the field after moving, the plants are girdled by cutting the vine about two-thirds through about 6 in. from the ground. Uniform moisture supply is maintained at all times. When flowering occurs, a paper clip is placed late in the afternoon over the tip of the flowering bud to open the following day. Between 5 and 6 a. m. on the following morning the flower is emasculated and again closed by placing the clip over the tip. Crossings are made between 8 and 10 a. m. and the flowers tagged, and the clip replaced to prevent insect visitation. Seed capsules about two-thirds grown are covered with a small cloth bag until the seed is mature. The seed can be planted at once or stored. At planting time the seed should be treated for 20 min. with concentrated sulfuric acid to insure immediate germination and then washed thoroughly to remove all acid before planting.

Sweet potatoes: A summary of results of recent fertilizer experiments. R. SCHMIDT. (*N. C. Expt. Sta.*). (*Com. Fert.*, 58 (1939), No. 3, pp. 12-14).—Review of recent fertilizer experiments with sweetpotatoes, largely noted earlier, showed plant food needs to differ extensively with locality.

The influence of nitrogen on grade and shape of Triumph sweetpotatoes in Mississippi, W. S. ANDERSON. (Miss. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 605-608).—Increasing the nitrogen content of the fertilizer from 2 to 8 percent, with phosphorus held at 8 and potash at 4 percent, had no apparent effects on the proportions of the various grades nor on the shape of the roots of Triumph sweetpotatoes grown on different soils, 1935-38 (E. S. R., 79, p. 624), at Laurel, Miss.

Influence of lime and calcium chloride applications on growth and yield of sweetpotatoes, C. E. STEINBAUER and J. H. BEATTIE. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 526-532).—That as many as five heavy annual applications of lime to a soil originally quite acid may not significantly change color, or edible quality, but may slightly reduce yields of sweetpotatoes and markedly alter the soil reaction, was observed in tests, 1933-37, at Beltsville, Md. There were some indications that heavy applications of calcium chloride under the same conditions might increase the total yield and the proportion of large size sweetpotatoes in certain varieties without altering root color or edible quality. The results confirmed suggestions of others that sweetpotatoes are not very exacting as to soil acidity. Apparently they do best in a slightly to moderately acid soil, and yields may be somewhat decreased when the soil becomes neutral or alkaline.

Curing temperature in relation to storage quality of three varieties of sweet potatoes, H. B. CORDNER. (Okla. A. and M. Col.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 569-571).—Roots of Nancy Hall sweetpotatoes shrank least in storage and kept satisfactorily following curing at as low as 70° F. Porto Rico roots kept best after curing at 92° with slightly greater storage losses following curing at 80°. The greatest storage losses were found in roots of the Maryland Golden, where it seemed imperative that a high curing temperature, about 90°, be used. Some attention evidently should be paid to relative humidity in the storage environment to avoid shriveling of roots of Maryland Golden.

Tobacco Substation at Windsor, report for 1938, P. J. ANDERSON, T. R. SWANBACK, and O. E. STREET (*Connecticut [New Haven] Sta. Bul.* 422 (1939), pp. 49, figs. 23).—Fertilizer and cultural investigations with cigar leaf tobacco (E. S. R., 79, p. 328) are reported on again, with accounts of the incidence and control of diseases and insects noted on pages 530 and 540 of this issue. The 1938 season was very disastrous for tobacco growers in New England. Excessive rains in June and July were followed by the hurricane of September 21 and flood which destroyed many full curing sheds and their contents. While the Tobacco Substation sustained no serious loss to buildings or equipment in either case, the heavy summer rains so reduced the yield and quality of the crop that most fertilizer and cultural field tests were either ruined or results were unreliable.

Losses of fertilizer constituents by leaching during an abnormally wet growing season, M. F. Morgan and O. E. Street (pp. 6-16).—Rainfall totaling 16.28 in. during the growing season of tobacco set May 26, 1938, was chiefly concentrated in four storm periods in June and July, aggregating 13.50 in. The resultant leaching of 8.8 in. of water from areas cropped to tobacco removed from 100 to 120 lb. of nitrogen per acre from the entire soil column. The tobacco crop could obtain only from 40 to 60 lb. of nitrogen per acre of the 160 lb. liberated during the growing season under favorable conditions on soils normally fertilized, or less than half the quantity ordinarily used by an average crop. The conditions were compared with those of 1934, which had favorable rainfall distribution, 7.95 in. from May 26 to August 4, about normal, except for a 2-week dry period in mid-July.

Lysimeter data showed that in the 1938 growing season, normally fertilized sandy loam in tobacco lost through leaching nitrogen approximating 100-150 lb. per acre, potash 50-75, lime 140-160, and magnesia 30-40 lb. Leaching losses were generally in inverse proportion to the weight of crop. Intensive leaching from normally cropped and fertilized soils during the 1938 growing season caused losses exceeding amounts removed by heavy fall rains following the normal 1934 season approximating nitrogen 85-130 lb. per acre, potash 20-35, lime 100-120, and magnesia 25-30 lb. Both dry weight of the tobacco crop on lysimeters and percentage composition as to nitrogen were materially less in 1938 in all corresponding nitrogen treatments. Nitrogen taken up by the crop was usually about one-half that of 1934. In 1934 nitrate nitrogen leaching was materially less than the nitrogen in the crop and the 1938 leaching greatly in excess. Evidently in 1934 the leaching represented nitrogen not used by the crop, while in 1938 the nitrogen in the crop was chiefly a residue from leaching.

Calcium deficiency, T. R. Swanback (pp. 16-18).—Calcium deficiency observed in numerous fields of tobacco was attributed to excessive leaching rains. Soil under calcium-starved plants did not show unusually low pH values (about 5.0), but was negative for replaceable calcium. Growers had supplied little or no liming materials either for 1938 or, in some cases, for many years. In restoring the calcium supply of depleted soil, not more than 500 lb. of agricultural lime should be applied the first year in order to prevent fixation of minor elements, and up to 500 lb. per acre land plaster also may be applied.

Value of top-dressing the growing crop with additional fertilizer (pp. 19, 19).—Profitable results in yield and grade of leaf followed top dressings of 114 lb. additional nitrogen per acre in three applications on a very light soil and 90 lb. in two applications on a medium heavy soil.

Further trials with soybean oil meal (pp. 19, 20).—The merits of soybean meal compared with cottonseed meal were shown again, although the crop was greatly reduced in yield and quality. Averages, 1936-38, showed a higher yield and grade index and 13 percent higher crop value for soybean meal.

Time of harvesting Havana Seed tobacco, IV (pp. 20-22).—Findings, 1935-38, indicated that Havana Seed tobacco should remain in the field at least 3 weeks after topping and often up to 4 for optimum yield and grading. The same rule probably should apply to Broadleaf.

Variations in chemical composition of leaves according to position on the stalk (pp. 22-26).—Leaf-by-leaf analysis of tobacco of the 1936 crop (Havana Seed No. 211) revealed a gradual and regular increase in the percentage of total nitrogen from bottom to top, with the uppermost leaves containing about three times as much as the lowest. Since this increase was accompanied by corresponding increase in nicotine, the upper, darker leaves make a "stronger" smoke and must be more thoroughly fermented before they are satisfactory for cigars. Calcium and magnesium, higher in the lowest leaves, decreased regularly in each successively higher leaf until the percentages at the top were about one-half that of the bottom leaves. Potash also tended to decrease toward the top of the plant but the trend was not so definite. Analysis of a composite sample of all of the midribs stripped from the same leaves showed the nitrogen and magnesium percentages about the same as the average for the leaf blades, the potash extremely high, showing heavy translocation from the blade to the midrib during curing, and the calcium as low as in the top leaves, showing no translocation of this element into the midribs.
